inquiry brought out some very interesting and somewhat unexpected results. In the case of men engaged in heavy work the reduction in the number of hours actually worked weekly from fifty-eight to fifty-one increased the relative real output from 100 to 139, and the relative total output from 100 to 122. The results with women were similar but less striking. Speaking generally, the investigation showed that a reduction in the weekly hours of actual work, varying from seventy to twenty a week, in no case resulted eventually in more than an insignificant diminution of total output, and on the average produced a substantial increase. The fact that this change did not come about at once but was gradual, extending frequently over four months, is held to nullify the suggestion that the effect upon output was a mere consequence of the desire to earn the same weekly wages as before the hours were shortened. The true explanation, it is suggested, is that the worker finds, unconsciously and gradually by experience, that he can work more strenuously and quickly for a short-hour week than for a long-hour week. Another factor in the result is that the amount of time lost in commencing and stopping work was diminished. The memorandum recalls Professor Loveday's conclusion that the proportion of lost time due to sickness and other unavoidable causes is, as a rule, greatly under-estimated in factory records, and the proportion due to slackness consequently over-estimated. It was also his conclusion that long hours, much overtime, and especially Sunday labour, exert a pernicious effect upon health, especially in the heavy trades. Another point he brought out, which was known to some employers a good many years ago, is that to work before breakfast is a mistake; from the factory point of view the necessary reduction of hours may be compensated for, or even outweighed, by reduced absences, reduced waste of time, and greater vigour after taking food; the effect of hunger work upon health is bad. The Committee in its new memorandum expresses the opinion that, speaking generally, the hours of work should be fewer than those it originally thought justifiable. It does not lay down any general rule, but suggests that a scheme for each factory should be determined after consideration of a number of different factors, such as the exertion, physical and mental, involved in the work, and the individual capacity; and the factory conditions as to temperature, ventilation, and organization. Under the last named are included the efficiency of welfare supervision, the sufficiency and suitability of the food, canteen accommodation, and so on. Mention is also made of the influence of the arrangement of the hours of work, and of breaks and pauses, and of the housing accommodation and available means of transit to and from work. It is pointed out also that allowance should be made for the fact that the best hours of employment will not be the same for all processes in the same factory, and for the extent to which the pace of the work is governed by the machine.

THE EIGHT HOUR DAY OF THE INDIAN HUSBANDMAN.

THE affection of the late Sir George Birdwood for India and its inhabitants was so great that he was perhaps a little disposed to idealize the life of the Indian husbandman, but it is not without interest to note that he asserted that in the division of the twenty-four hours the Deccan *rayat* has for the past three thousand years realized the ideal of the English artisan, and at a twelfth of the cost: "Eight hours' work, eight hours' play, eight hours' sleep, and eight pennies (not shillings) a day." His justification is given in his essay on the Mahratta plough, published a quarter of a century ago, and republished a couple of years ago in a collection of his essays entitled, *SVA*. The Deccan husbandman, "the house father," is the first to rise. Just before dawn he arouses the bullocks and oxen, stalled either in a yard behind the house or in the porch in front.

Having got the cattle out into the road, and lit his cigarette of tobacco rolled in a leaf of the *apta* (*Bauhinia tomentosa*), and taken up his breakfast of *javari* or *bajri* cakes, cooked by his wife the day before, and tied up by her overnight in a cloth with an onion, or some pickle, he strolls off at daybreak, keeping his oxen before him, to his fields. There yoking the oxen, and stripping to his work, whether it be to plough and to sow, or to reap, he works on for a steady hour until eight o'clock; and again, after ten or twenty minutes spent in eating his breakfast, for four hard fagging hours more until midday. The wife, after grinding the corn and attending to the house, cooks the dinner, consisting of fresh-baked cakes of *bajri* or *javari* meal, and either a mess of pulse porridge or a pot of highly spiced pulse soup, and takes it to her husband by twelve o'clock. The cultivators within hail of each other generally take this meal together, spending from half an hour to an hour. Then up to two or half-past two the men lie down to sleep. When the men awake they re-yoke the oxen and resume their work for three hours more, or until the sun sets, at which signal they return in long winding lanes towards their respective villages, walking along leisurely, chatting and laughing, and always keeping their oxen before them. On reaching their homes they at once tie up the cattle, and then, after bathing and again worshipping the household gods, the husband at eight o'clock partakes of his supper of pulse porridge. He spends the rest of the evening in visiting the village shrines, gossiping with his neighbours, and in consulting the village astrologer as to the right day and hour for sowing different kinds of crops. By ten o'clock everybody is in bed. If we leave out the time taken in getting out and taking home his cattle and going to and from the field, this programme gives about eight hours' work. Sir George Birdwood claims that the Deccan *rayat* has realized, in its fullest security, the ideal co-operative life of the day-dreams of the socialists of the West, and that this co-operative agricultural life of the people of India is high farming in its noblest sense.

THE WASSERMANN REACTION.

THE public health department of the London County Council has issued to metropolitan medical practitioners a memorandum on the interpretation of the Wassermann reaction. It was originally drafted by the pathologist of one of the London hospitals, for use in the venereal department of that institution. It has since been submitted to the pathologists of the other London hospitals in which examinations are carried out under the scheme now in force, and the present leaflet embodies certain additions suggested by them. The opening paragraph admits that universal agreement has not been reached with regard to certain points, but claims that the enormous number of tests made during the past ten years leave no doubt as to the meaning to be attached to definitely positive or negative results in the great majority of cases. Since the Wassermann reaction is quantitative, there will always be border-line reactions, which, when they occur, must be carefully considered in relation to all the known facts of the case in question. The definite statement is made that a well-marked positive reaction, obtained with the full technique, or with a modification involving only unessential details, justifies a definite diagnosis of syphilitic infection, provided that leprosy, yaws, and perhaps sleeping sickness, can be excluded—conditions which can seldom enter into consideration in this country. A positive Wassermann reaction is sometimes obtained in malarial cases, where there is a complete absence of symptoms of syphilis and no suggestion, in history or otherwise, of a previous taint; and this point must be taken into consideration in certain cases. The memorandum goes on to consider the subject under the headings of "the reaction in diagnosis"; "the effect of treatment on

the reaction"; "the reaction on the control of treatment"; and on "the reaction as a criterion of infectivity." Under the last head it is stated that if a positive reaction is well marked it is, with the reservations outlined above, undoubted evidence of syphilitic infection, but that if weak it has little diagnostic value and must always be considered in relation to all the known facts of the case. With regard to a single negative result it is said that it has no diagnostic value during the first few weeks of the disease, nor in a patient undergoing treatment. A negative result in an untreated case exhibiting suspected secondary lesions almost excludes syphilis, but never absolutely. In the later stages, with certain exceptions, a rather higher proportion of undoubted syphilitic cases give negative results, so that such a result, while contraindicating a diagnosis of the disease, especially if previous antisyphilitic treatment can be excluded, must be regarded in relation to all other available evidence. In using the reaction to control treatment, the ideal aimed at should be a persistently negative reaction following a prolonged and thorough course of treatment. This result, combined with the absence of all clinical signs, is the best evidence of non-infectivity.

THE TREATMENT OF MALARIA.

PROVISIONAL instructions for the treatment of cases of malaria in the United Kingdom, printed in the *Journal of the Royal Army Medical Corps*, September, 1917, are based upon work done in special malaria wards in England during the preceding five months by a number of specially qualified medical officers. No line of treatment yet tried (and more than twenty different lines have been tried) has sufficed to eradicate the infection entirely in more than a small percentage of cases, and no clear indication has yet been obtained that any one line of treatment is much better in this respect than any other. A series of new instructions is given as regards dosage and other points. It has been decided that every case of malaria should be given sixty grains of quinine every week until he has been free from malarial fever for at least sixty days. The dose may be administered intramuscularly or by the mouth in the form of sulphate, hydrochloride, or bi-hydrochloride, and it may be given at the rate of ten grains daily on six days in the week, or of fifteen grains daily on four days in the week, or of twenty grains on three days in the week, or of thirty grains on two days of the week, on consecutive days or not. The individual dose may be five grains, ten grains, or more, in solution, powder, or tablet, as convenient. It will thus be seen that it is not easy to stamp out the infection of malaria. This is pretty much what the old clinicians found and taught. The only way to ensure success is to continue the drug over long periods, and the plan of giving sixty grains a week is useful, but it must be kept up for two months or for three if possible. The difficulty in dealing with large bodies of men is to be certain that they will go on taking the drug regularly; it is in private practice that the best results of quinine treatment are obtained. A word of warning may be given as regards pills and tablets; they may, especially if sugar-coated or old, pass quite unchanged, and in such a case the patient is not being treated at all. Fresh tabloids not sugar-coated seem to dissolve very well, however, but if symptoms of fever continue the possibility that they are not being dissolved should be borne in mind.

THE INTERESTS OF ABSENT COLLEAGUES.

DR. J. C. VERCO, in his presidential address delivered at the annual meeting of the South Australian Branch of the British Medical Association, made many interesting references to the part played by the medical men of South Australia in the war. The medical profession of the State is so completely organized, and individual practitioners have come forward in such numbers, that the principal medical officer has so far been able to meet the demands of the Director-General, Medical Services, as they have

arisen. Should it be decided to conscribe the whole medical profession of Australia for service at home or abroad the position in South Australia would be scarcely changed, since almost every medical man has already offered himself for military service. In this connexion Dr. Verco paid an eloquent tribute to those of his colleagues who are now serving with the Australian Forces or in the Royal Army Medical Corps, and especially to those who have given their lives for their country and those who have returned broken in the war. He made an appeal for the highest standard of loyalty towards the professional interests of practitioners absent on active service. Those remaining at home should put themselves as completely in the place of their absent colleagues as they can, in the delicate circumstances of private practice, in contract work, in salaried posts, and in all positions of prestige and public importance connected with charitable institutions. In the absence on military service of those who by right of seniority would naturally obtain hospital posts as they fell vacant, there came a chance for the man on the spot to "jump the claim." None but the most selfish and unpatriotic would, however, seize such an opportunity, and Dr. Verco suggested that the proper course for the institutional authorities would be to fill vacancies on their staff temporarily by the appointment of acting physicians and surgeons, deferring all permanent appointments until the war is over. "It will hearten the men at the front," he said, "to know that their interests are being conserved by their medical brethren and close competitors, as well as by the boards of management of the institutions. We are glad to see that the Adelaide Hospital management are acting upon this honourable and patriotic principle. In an equal degree does this apply to the lecturers, demonstrators, tutors, etc., in connexion with our university. . . . All absent men should be made to feel and led to know the security of the university posts they so reluctantly left, and which they so highly prize." In the interests of the younger men who have gone away almost immediately after qualification without even the advantage of holding a resident appointment, Dr. Verco proposed that some scheme should be devised whereby advanced teaching, especially of a practical character, should be given them on their return. He suggested further that a fund should be established within the Branch for the purpose of helping in every reasonable way members who have been to the war and require assistance on their return. Out of this fund grants might be made for the support of those who went away immediately after graduation and who wished to fit themselves further for their life's work; financial aid could be given to those who have lost their health or who come back to ruined practices, and others in temporary need could be helped to make a start in life.

OTHAEMATOMA AS A DISEASE OF PRISONERS.

FROM the bad hygienic and dietetic conditions in the German prison camps many infective and dietetic diseases, such as typhus, scurvy, general oedema, eruptions, sub-acute nephritis, and day blindness, occur. P.-L. Marie,¹ who for nearly ten months looked after fellow prisoners of various nationalities at Zossen, noticed that day blindness was confined to Russians, who were in a much worse condition of health than the French. In April, May, and June, 1915, he saw ten cases of othaematoma among French and Belgium prisoners who were perfectly sane, had not received any local injury, or recently had any serious disease. It appeared at a time when general nutrition was very low and cases of scurvy were occurring. As the cases ceased to appear when green vegetables became obtainable it is probable that this condition was at least favoured by scurvy due to improper food. Othaematoma, or haematoma auris, occurs so frequently in the insane that it has been called "insane ear." It follows

¹ P.-L. Marie, *Arch. de méd. et de pharm. mil.*, 1917, lxxvii, 501-505.

some slight injury, and, according to Ford Robertson, the primary lesion is degeneration of the cartilage of the ear, followed by the formation of cysts, which degenerate and become filled with blood. By the continuance of the haemorrhage the perichondrium is stripped off and the swelling increases in size. The pathology of othaematoma in prisoners is probably somewhat different, but trauma may play some part in it, for a similar condition is sometimes seen in footballers.

NOTIFICATION OF INFECTIOUS DISEASES.

WE hear that medical officers of health in various parts of the country are complaining of the failure on the part of many medical practitioners to notify cases of infectious disease. It is unnecessary to point out the importance of prompt notification, which is a key to the control of the spread of infectious disease. We are well aware of the strenuous conditions under which most civilian practitioners are now working, but this duty must be fulfilled at all costs. It is against all public interest that any avoidable risk should be run of undermining our defences against epidemics. The lowering of the notification fee from 2s. 6d. to a shilling was a paltry piece of economy, which the Local Government Board probably regrets by now. The medical profession quite properly protested against it, but no excuse must be given to the enemies of medicine for the suggestion that carelessness in the public duty of notification is due to resentment at the size of the fee.

Medical Notes in Parliament.

Midwives (Ireland) Bill.—The Chief Secretary for Ireland, Mr. Duke, introduced the Midwives (Ireland) Bill in the House of Commons on November 12th. The bill is substantially on the lines of the English and Scottish Midwives Acts, but owing to the difference in the conditions of medical practice in Ireland there will be some fundamental variations in its administration. Clause 1 (2) provides that from and after January 1st, 1924, no uncertified woman shall habitually and for gain attend women in childbirth otherwise than under the direction of a registered medical practitioner unless she be certified under the Act. To this clause, which is identical with the corresponding section of the English and Scottish Acts, Irish dispensary doctors took exception some time ago when the Irish Bill was being drafted. In Ireland there is no difficulty in summoning the dispensary doctor on a visiting ticket under the Medical Charities Acts. Fully 50 per cent. of the parturient women in Ireland can command the services of the Poor Law medical officers, who receive no extra fees for their attendance in midwifery cases. The dispensary doctors fear that, should the Midwives (Ireland) Bill become operative with the clause, uncertified midwives, in order to protect themselves from the penalties provided under paragraph (2) of Clause I, will in all cases secure their services under the Medical Charities Acts. At the present time dispensary doctors are only summoned to attend abnormal cases. It appears that the warning issued by the General Medical Council in connexion with medical practitioners attending midwifery cases with uncertified nurses under the English and Scottish Acts, would also apply to dispensary doctors under an Irish Midwives Act. The Irish Poor Law Committee made strong representation to the Local Government Board on this point, but it would seem now without effect. By Clause 16 the council of a county or county borough will be the local supervising authority, but may delegate its powers to a committee, consisting wholly, or to the extent of two thirds or more, of members of the authority; women are eligible to serve on such committees. In every county borough the medical superintendent officer of health shall be the medical officer for the purposes of the Act, with such additional remuneration as the council may, with the approval of the Local Government Board, determine. The council of any county may appoint a registered medical practitioner having such qualifications as may be approved by the Local Government Board. Clause 22 (1) provides that in case of an emergency a midwife shall call into her

assistance a registered medical practitioner, and the local supervising authority shall (unless the patient is entitled to relief under Section 9 of the Poor Relief (Ireland) Act, 1851) pay to such medical practitioner a fee according to a scale to be fixed by the Local Government Board.

Fees for Post-mortem Examinations.—Mr. Ingleby asked the Home Secretary if he was aware that in cases where a patient was brought into hospital in a moribund condition and a *post-mortem* examination had to be made and an inquest held, the medical officer who undertook the necropsy and subsequently attended the inquest to give evidence was precluded by Section II, Clause 22, of Part II of the Coroners Act, 1887, from receiving any fee, whereas if the patient was dead before being received into hospital the medical officer was, under Section I, entitled to receive £2 2s. for his services. Mr. Ingleby further asked if the Home Secretary was aware that coroners had from time to time expressed their opinion in court as to the injustice suffered by the medical profession in this matter, and whether he would introduce a short bill repealing Section II of the Act referred to. Sir George Cave replied that he believed that the facts were as stated in the question, but he did not see his way to propose legislation on the subject at present. Mr. Ingleby asked whether the matter had not been dealt with in the report of a Departmental Committee of the Home Office seven or eight years ago. Sir G. Cave: I cannot say without reference; but I think it is a matter which has been discussed on both sides for some years. Sir William Collins asked whether it was not the case that the disability referred to in the question dated from the time of the Burke and Hare murders, and whether the condition of things then obtaining was not rendered obsolete by the Anatomy Act, 1832. Sir G. Cave: That may be so.

Public Health Legislation.—On November 19th, in reply to Mr. Anderson, the President of the Local Government Board said that he had already forwarded a request that he might be allowed to introduce a bill to give the local authorities in England and Wales the same powers that the Scottish local authorities had in matters relating to maternity and infant welfare. In reply to a further inquiry on November 20th, Mr. Bonar Law said that the introduction of legislation was under consideration, but he could not at present see an opportunity for a discussion of the subject in the House as Mr. Anderson desired.

Insurance Amendment Bill.—It is understood that if the Government is successful in securing the second reading of the National Health Insurance amending bill, it will be referred to Grand Committee.

Medical Certificates for Wheaten Flour.—In reply to Sir William Collins, the Parliamentary Secretary to the Ministry of Food said that every application for permission to use wheaten flour was considered and dealt with on its merits. In view, however, of the fact that these applications showed a considerable increase in number and frequently appeared to be based on insufficient grounds, it was determined, after consultation with the War Bread Medical Subcommittee of the Royal Society, to issue the memorandum published on October 20th in the BRITISH MEDICAL JOURNAL and the *Lancet*. Applications were considered in the first instance by the scientific adviser to the Food Controller; doubtful cases were referred to Sir Thomas Barlow and Dr. Robert Hutchison, who had agreed to act as honorary medical referees.

Care of the Blind.—In reply to Mr. Acland Allen, Mr. Hayes Fisher said that in order to carry into effect the main recommendations of the Departmental Committee on the Blind the Cabinet had decided to authorize the setting up of special departments in the Local Government Board and in the Local Government Board for Scotland respectively and the establishment of an Advisory Committee for England and Wales and of a separate Advisory Committee for Scotland, and had sanctioned the necessary expenditure for the immediate administrative expenses consequent on their decision.

British and Turkish Prisoners of War.—Mr. J. Fitzalan Hope, in reply to Mr. George Lambert, stated on November 19th that the British Government had heard after much delay that the Turkish Government were willing to send delegates to Switzerland to discuss the whole question of prisoners of war with British representatives. There was a great preponderance of Turkish prisoners in British hands, their numbers being at present probably 45,000 as against about 8,000 British and Indian in Turkish hands, who were believed to have survived the rigours of their captivity.

THE WAR.

MACEDONIA.

THE dispatch from Lieut.-General G. F. Milne, C.B., Commanding-in-Chief British Salonica Force, dealing with the period from October 9th, 1916, to October 1st, 1917, was published in the *Supplement* to the *London Gazette* of November 13th. From November 29th, 1916, the British Force has occupied the front covering Salonica from the east and north, and extending from the mouth of the river Struma to the river Vardar, a distance of approximately 90 miles. The holding of this long line placed a considerable strain on the endurance of the troops, especially during the winter months, when, owing to unprecedented rainfall, the mountain roads became almost impassable, so that the difficulty of maintaining supplies was overcome only by the energy and determination of all concerned. In spite of the fact that the whole of the force was in the line without relief for over a year, with only occasional limited opportunities for training, and without the encouraging effect upon them of offensive action, a very high standard of efficiency and moral was maintained.

A limited advance was made on May 8th, but on May 24th instructions were received from General Sarraill that offensive operations were to cease all along the front. As summer was commencing, the best means of maintaining the health of the army during a period when malaria and dysentery are more or less prevalent in the low-lying areas had to be considered. In view of the experience gained in the previous year, and in spite of the fact that a considerable amount of antimalarial work had been carried out in the valleys during the winter, General Milne decided to abandon the forward positions on the right and centre of the line, and to retire to the foothills on the right bank of the Struma river, and to the south of the Butkova valley. This withdrawal was carried out by June 14th without interference by the enemy. In 1915, apart from two partially-metalled roads, one to Monastir and the other to Seres, both in bad condition, no roadway possible for mechanical transport existed. These two roads have been improved, widened, and drained; cross roads have been cut through the hills, new roads in base and forward areas constructed, and old ones repaired. Another main route has been constructed from Salonica to Kukus, and thence to the front on either side of Lake Doiran. New railways have been constructed, the dock system supplemented, and hospitals expanded. With regard to the health of the troops, General Milne writes as follows:

The health of the troops has been on the whole satisfactory. With the advent of the cold weather malaria abated rapidly, and the sick rate remained low during the winter. Preparations for the next summer in the form of antimalarial work were, however, steadily pursued, drainage of swamps and canalization of streams were extended, and the personnel for technical work strengthened; but what proved of almost greater importance was the instruction of all ranks in the value of field sanitation and the prevention of disease in the field. The results have been most satisfactory, and, while giving full credit to the various ranks of the medical services and to the devoted band of nursing sisters, I consider that the great diminution in disease in this army as compared with last summer is due chiefly to the fact that the value of preventive measures is fully realized by all ranks, and that the whole army has profited by the experience of last year.

The arrangements for retaining all sick and wounded in this theatre have worked most satisfactorily, and the decision has, in my opinion, much to recommend it. The arrival of sufficient transport and the opening up of new roads has permitted the establishment in the hills of hospitals and convalescent camps, where, under trained instructors, convalescents are put through a graduated course of physical drill before returning to the depôts.

As regards the general work of the Royal Army Medical Corps and the assistance afforded by the British Red Cross Society and the Order of St. John, I can only reiterate the remarks contained in my last dispatch.

General Milne concludes his dispatch by stating that in due course he proposes to submit a list of officers, non-commissioned officers, and men whose distinguished and gallant services specially deserve mention and reward.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

CAPTAIN J. FOX-RUSSELL, M.C., R.A.M.C.(T.F.).

Captain J. Fox-Russell, R.A.M.C.(T.F.), was killed in action on November 6th. He was the eldest son of Dr. Fox-Russell of Holyhead, and was educated at the Middlesex Hospital, taking the diplomas of M.R.C.S. and L.M.S.S.A. in 1916. For some time before the war he had held a commission in the 6th (Carnarvonshire and Anglesey Territorial) battalion of the Royal Welsh Fusiliers, in which he attained the rank of captain on January 27th, 1915. On qualifying he transferred to the R.A.M.C., and after serving for some time as medical officer to a brigade of field artillery, was transferred in the same capacity to his old regiment. He had recently received the Military Cross for gallantry in the field.

CAPTAIN R. A. IRELAND, C.A.M.C.

Captain R. A. Ireland, Canadian Army Medical Corps, was reported as killed in action, in the casualty list published on November 14th.

CAPTAIN E. PHILLIPS, R.A.M.C.

Captain Edwin Phillips, R.A.M.C., was killed in action on November 6th. He was educated at the Newcastle-on-Tyne school of medicine and at the London Hospital, and graduated M.B. and B.S.Durh. in 1913, also taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in the same year. After acting as emergency officer at the London Hospital, and as house-physician of the Poplar Hospital, he entered the army as lieutenant on July 31st, 1914, and was promoted to captain on March 30th, 1915.

Died of Wounds.

CAPTAIN G. E. CHISSELL, R.A.M.C.

Captain George Edwin Chissell, R.A.M.C., was reported as having died of wounds, in the casualty list published on November 14th. He was educated at the Middlesex Hospital, took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1916, and subsequently took a temporary commission as lieutenant in the R.A.M.C., being promoted to captain after a year's service.

Died on Service.

LIEUTENANT E. S. BAILLIE, I.S.M.D.

Lieutenant Edwin Stirling Baillie, I.S.M.D., died suddenly of heart disease at Lahore on September 10th. He entered the I.S.M.D. as a hospital apprentice in 1880, passed through the Calcutta Medical College in 1881-85, and attained the grade of senior assistant surgeon and the rank of lieutenant on November 2nd, 1908. He served for four years, 1885-89, in the Burma war, but had put in most of his service in civil employ in the Punjab. He retired on May 1st, 1911, but rejoined for service during the war in 1915, and was posted as assistant to the civil surgeon of Lahore.

LIEUTENANT H. F. RANSOME, R.A.M.C.

Lieutenant Herbert Fullarton Ransome, R.A.M.C., died on November 14th, at Queen Mary's Hospital, Whalley Lancashire, in which he was serving as surgeon. He was educated at Owens College, Manchester, and at St. George's Hospital, and took the diplomas of M.R.C.S., L.R.C.P.Lond. and L.S.A. in 1892. After filling the post of honorary assistant medical officer to the Manchester Hospital for Consumption and Diseases of the Throat, he went into practice at Bowdon, Altrincham, where he was surgeon to the Altrincham Hospital and Dispensary. He had only recently taken a temporary commission as lieutenant in the R.A.M.C.

LIEUTENANT G. TAYLOR, R.A.M.C.

Lieutenant G. Taylor, R.A.M.C., was reported as having died on service, in the casualty list published on November 17th.

Wounded.

Major W. Bapty, Canadian A.M.C.

Major A. V. Meehan, Australian A.M.C.

Captain J. Dunbar, R.A.M.C. (temporary).

Captain H. F. Dunstan, Australian A.M.C.

Captain G. D. Eccles, R.A.M.C. (temporary).

Captain O. J. Ellis, Australian A.M.C.

Captain T. G. Featherstonhaugh, R.A.M.C. (temporary).
 Captain J. H. Fletcher, D.S.O., M.C., R.A.M.C. (temporary).
 Captain J. M. Forsyth, M.C., R.A.M.C. (temporary).
 Captain H. W. Gush, R.A.M.C. (temporary).
 Captain W. Harmens, R.A.M.C. (temporary).
 Captain A. J. Howard, Australian A.M.C.
 Captain F. R. Joscelyne, M.C., R.A.M.C. (temporary).
 Captain D. G. Kennard, R.A.M.C. (temporary).
 Captain J. Morgan, Australian A.M.C.
 Captain J. P. Peake, Canadian A.M.C.
 Captain M. P. Power, R.A.M.C. (temporary).
 Captain H. G. Rice, R.A.M.C. (temporary).
 Captain G. S. Sutherland, R.A.M.C. (temporary).
 Captain R. M. Thomson, Australian A.M.C.
 Captain J. Young, R.A.M.C. (temporary).
 Lieutenant J. Avery, R.A.M.C. (temporary).
 Sister M. Stewart, Q.A.I.M.N.S.R.

DEATHS AMONG SONS OF MEDICAL MEN.

Almon, John Egan, Lieutenant Canadian Infantry, younger son of the late Dr. T. R. Almon of Halifax, Canada, killed November 1st.

Bennett, Vivian Wilfrid, Lieutenant Royal Engineers, eldest son of Lieut.-Colonel V. B. Bennett, I.M.S., killed October 21st, aged 21. He was educated at Westward Ho! and at Malvern, entered Woolwich in 1916, got his commission six months later, was wounded at Armentières in September, 1916, and returned to the front in September last.

Cox, Claude E. Lane, Private Canadian Infantry, eldest son of A. E. Cox, M.B., of Grange-over-Sands, late of Southport, killed November 1st, aged 24. He had been slightly wounded two days before but remained on duty.

Devlin, Francis Cecil Cochrane, Lieutenant West Africa Frontier Force, youngest son of Captain T. P. Devlin, R.A.M.C., of Balfour, British Columbia, killed in East Africa, October 16th, aged 19.

Finlay, George Malcolm, Captain Hampshire Regiment, late Leinster Regiment, youngest son of Colonel Finlay, R.A.M.C. (retired), killed November 5th.

Harris, King Davie, Corporal Hussars, attached Royal Warwickshire Regiment, younger son of the late Colonel F. W. H. Davie Harris, R.A.M.C., killed October 26th, aged 29.

McRae, Alec Mackenzie, youngest son of Dr. Donald McRae of London, killed October 28th.

Spence, Geoffrey Shalders, Second Lieutenant South Wales Borderers, son of the late Dr. W. J. Spence, of Bedford, died of malaria contracted on the Salonica Front on April 15th, 1917, at Millbank Hospital.

Streatfeild, Thomas Basil Maryon, Second Lieutenant Royal West Kent Regiment, only son of Dr. Thomas Streatfeild of Folkestone, killed November 7th, aged 19. He was educated at Sherborne, got his commission on September 18th, 1917, and went to the front on October 15th.

Waller, Thomas Henry Whalley, Lieutenant Gloucestershire Regiment, only son of Dr. A. W. Waller of Stroud, Gloucestershire, killed October 22nd, aged 21. He was educated at Malvern, and had registered as a medical student, intending to proceed to Cambridge, but got his commission direct from the Malvern O.T.C. He had served in France for eighteen months, including the battle of the Somme.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SPECIAL Supplement to the *London Gazette*, issued on November 19th, contains a further list of awards for gallantry and distinguished service in the field. The acts of gallantry for which the decorations are bestowed will be announced at a later date. The following medical officers are awarded the decorations indicated:

Distinguished Service Order.

Majors: Sydney Vere Appleyard, A.A.M.C., and William Wallace Stewart Johnston, M.C., A.A.M.C.

Temporary Captain Gordon Watson Armstrong, R.A.M.C.

Bar to the Military Cross.

Captain William McMeekin Chesney, M.C., M.B., R.A.M.C. Spec. Res. (M.C. gazetted June 23rd, 1917).

Temporary Captains: Robert Welton Hogg, M.C., M.B., R.A.M.C. (M.C. gazetted December 11th, 1916); Maurice Bertram Lawrie, M.C., S.A.M.C. (M.C. gazetted July 26th, 1917); Hubert Francis Wilson, M.C., M.B., R.A.M.C. (M.C. gazetted September 26th, 1917).

Military Cross.

Captains: Bernard Gordon Beveridge, R.A.M.C., Vernon Carlisle Brown, A.A.M.C., George Eustace, M.D., R.A.M.C., Frederick George Harper, M.D., R.A.M.C., Charles Hallily Kellaway, A.A.M.C., Harold Howard Leeson, R.A.M.C., James Stewart McConnachie, R.A.M.C., Patrick Joseph Francis O'Shea, A.A.M.C.

Temporary Captains: Dimock Stanley Cassidy, M.D., R.A.M.C. (late C.A.M.C.), James Jack, M.B., R.A.M.C., Charles Fellowes MacLachlan, R.A.M.C., Peter Malcolm MacLachlan, M.D., R.A.M.C., Alexander Waugh Young, M.D., R.A.M.C.

The King has conferred the Albert Medal upon Surgeon Probationer Robert Sydney Steele Smith, R.N.V.R.

Surgeon Probationer Smith was medical officer of one of his Majesty's ships which was torpedoed by an enemy submarine. When the enemy torpedo struck the ship Surgeon Probationer Smith was in the ward-room aft with the first lieutenant. The explosion wrecked the ward-room and rendered the first lieutenant unconscious. All other exits being blocked, Surgeon Probationer Smith piled the wrecked furniture under the skylight, and got the first lieutenant through this on deck. He then attended to a petty officer who was lying on deck with a broken arm and leg, adjusted and blew up his life-belt, and after doing the same for the first lieutenant got him overboard, as the ship was then foundering. The first lieutenant was by then partially conscious, but was again stunned owing to an explosion when the vessel foundered, and when he was picked up by the boat he was apparently dead. Surgeon Probationer Smith applied artificial respiration until the first lieutenant showed signs of life; he afterwards attended to the injured in the boat so far as the circumstances allowed, until they were picked up forty-three hours later.

The Distinguished Conduct Medal has been awarded to two non-commissioned officers and four privates of the R.A.M.C., four non-commissioned officers of the A.A.M.C., and two of the C.A.M.C.

The Military Medal has been granted to twelve non-commissioned officers and twenty-nine privates of the R.A.M.C., two non-commissioned officers and two privates of the A.A.M.C., and three non-commissioned officers and three privates of the C.A.M.C.

FOREIGN DECORATIONS.

Mr. James Berry, F.R.C.S., has received the King's permission to wear the Insignia of the Fourth Class of the Order of the Star of Rumania (with swords), and the Insignia of the Third Class of the Order of St. Sava, conferred upon him by the Kings of Rumania and Serbia respectively in recognition of services rendered to the sick and wounded during the present war.

The King of Italy has conferred the silver medal for military valour upon Deputy Surgeon-General Octavius W. Andrews, M.B., R.N., and Fleet Surgeon George E. Duncan, R.N., for distinguished services during the war.

TUBERCULOUS SOLDIERS.

An Army Council Instruction states that in all cases in which officers or soldiers have developed pulmonary tuberculosis during overseas service, it will be regarded as caused or aggravated by military service. The same assumption will apply to all other cases unless the military board is satisfied that pulmonary tuberculosis was present previous to the man's enlistment, or to the granting of the officer's commission, or that it was not aggravated by his service.

England and Wales.

OPHTHALMIA NEONATORUM: VENEREAL DISEASE IN MENTAL DEFICIENTS.

THE Public Health Committee of the London County Council has reported an interview it had held with a deputation from the British Medical Association (Metropolitan Counties Branch) urging the necessity for arrangements being made for the treatment of ophthalmia neonatorum in London. The committee decided to consider the matter in connexion with the arrangements for 1918 for the treatment of venereal diseases under the Council's scheme. The question of the treatment of venereal diseases in mentally deficient persons was also to be considered in connexion with the arrangements for 1918. The committee reported that expenditure not exceeding £5,000 had been authorized in respect of the supply of salvarsan substitutes during the year 1917-18.

PROPOSALS FOR A MINISTRY OF HEALTH.

The President of the Local Government Board received two deputations on November 17th with reference to the proposals for the establishment of a Ministry of Health.

The first was representative of various women's organizations. Miss Llewellyn Davies, who introduced the deputation, said that its object was to appeal to the Local Government Board to take action towards establishing a Ministry of Health, and to ask that extended powers should be given to local health authorities. The basis of the new ministry should be the public health side of the Local Government Board; it should take into partnership the National Insurance Commissioners, and dissociate itself from the Poor Law system.

Mr. Hayes Fisher, in reply, after observing that in relation to the health of the people housing was at the root of almost everything, said that the Local Government Board, if it were reorganized, might perfectly well be the central

authority to direct and carry out the new health policy. The Board was not wedded to Poor Law administration. The Poor Law was in the melting pot; it was being considered by a Subcommittee of the Reconstruction Committee. The local authorities had a rival in the Insurance Committees, and the Government would have to decide between them. He considered that fuller powers should be given to urban local authorities and that the same powers that had been given to Scottish and Irish local authorities should be given to those in England and Wales. The difference between the departments concerned should be settled by an independent body before which the Local Government Board would urge that it should be the chief advising authority of all the local authorities in administering health policy. The Board hoped to bring forward schemes for the extension of infant welfare and maternity, and these could be carried out within six months of the cessation of war. The question of some form of union between the Board and the National Insurance Commissioners was now before the Cabinet.

The second deputation was from the Society of Medical Officers of Health and the Association of County Medical Officers of Health. It was introduced by Dr. Charles Sanders of West Ham, President of the Society, and the speakers included Dr. John Robertson (Birmingham), Professor Bostock Hill (Warwickshire), Dr. Allan (Westminster), and Colonel J. R. Kaye, Medical Officer, West Riding.

Mr. Hayes Fisher, in his reply, while admitting that the scheme for co-ordination at the centre was good, said that a perfect scheme for a new Ministry of Health on such lines would mean the taking of certain powers from one department and adding them to another. If he asked for transfer to the Local Government Board he would be accused of poaching, and if he suggested that the health powers of the Local Government Board should be vested in a new body and the Board left with the administration of the Poor Law he would be performing *hara-kiri*. The Local Government Board desired to obtain a bill that would enable local authorities in England and Wales to do all that was being asked by the proposed Ministry of Health. The bill had not made progress because the National Insurance Commissioners were asking for similar powers in respect of infant welfare and maternity. Whatever happened, the responsibility for the carrying out of the new powers would rest with the medical officers of health; as their responsibilities increased their tenure of office should be made certain against any reaction on the part of the authorities, and they should have the right of appeal to some responsible body, remuneration for extra duties, and proper and adequate salaries.

THE LIVERPOOL MEDICAL INSTITUTION.

At the ordinary meeting on November 15th, Mr. Charles J. Macalister in the chair, Captain Keith W. Monsarrat read a note on infected gunshot wounds of the knee-joint, based on experience of cases among Serbian and Bulgars which came under his observation at Salonica. Dr. Glynn gave a paper, entitled "The teaching and practice of medicine of my student days and of the present time contrasted." Many of his old students of the Faculty were present and appreciated his vivid contrasts between student life of over fifty years ago and present-day students. Dr. Glynn, who entered St. Bartholomew's Hospital in 1860, passed in rapid survey the doctrines in medicine then taught by Watson and other physicians, their rehabilitation or disestablishment in the light of recent research. He illustrated this statement by quoting from Watson's *Principles and Practice of Physic* the author's views on tubercle and scrofula, and said that he had witnessed also the introduction of the clinical thermometer and of the microscope. Dr. Glynn's observations on these aids to clinical medicine and the rancorous discussion they sometimes provoked between those who approved of and those who frowned upon the innovations caused much amusement. The paper was a critical survey interspersed with anecdotes of medicine over fifty years ago, and was much enjoyed by those present. Drs. Caton, Stookes, and Humphreys also contributed experiences of their student days.

CENTRAL MIDWIVES BOARD.

At a meeting of the Central Midwives Board on November 15th, Sir Francis Champneys in the chair, it was decided that at the next revision of the rules

consideration should be given to the opinion of a London coroner that the prescribed form of sending for medical help ought not to specify any doctor by name. With reference to a communication from the General Secretary of the Medical Defence Union, it was agreed to reply that "where a complaint for which an appropriate remedy is provided by due course of law is made against a midwife, it is contrary to the practice of the Board to deal with the midwife until the complainant has exhausted his remedy at law." At special meetings of the Board, on November 14th and 15th, fourteen midwives were cited to appear, and ten of these were struck off the roll; the charges included nine of neglect in cases of ophthalmia neonatorum. Most of the women were bona fide midwives, their ages ranging from 60 to 78.

Ireland.

IRISH NURSING BOARD.

DR. T. P. C. KIRKPATRICK, Fellow and Registrar of the Royal College of Physicians of Ireland, in a very comprehensive lecture recently delivered in the Dublin Metropolitan Technical School for Nurses, said that in Ireland a great effort had been made this year to improve the teaching of nurses, although the idea, started by the Hon. Arthur Stanley, Chairman of the Joint Committee of the Red Cross and the St. John Ambulance Societies, of a voluntary college and register for nurses, seemed to be excellent in many ways; the methods by which it was proposed to give effect to it were not so satisfactory. In the first place, the control of the college and of the nurses was to be largely in the hands of persons who were not themselves nurses, and who did not appear to be directly conversant with the needs of the nursing profession. The nurses were to be regulated, not to regulate themselves. These defects were so serious that many nurses felt that they could not join the college; the result has been the formation of the Irish Nursing Board under the approval of the Royal College of Surgeons in Ireland. This board consists of four medical men, elected by the College of Surgeons, and of twenty-two nurses elected by nurses. Thus the conduct of its business will be almost entirely in the hands of nurses. The board has two chief objects in view: first, the formation of a voluntary register of all trained nurses; and, secondly, the improvement of the training of those who seek to become nurses. Registration by the Irish Board will, it is hoped, confer two great benefits on the individual nurse: first, the certificate of registration will be a valuable diploma. It will be a guarantee to the public that the holder has satisfied the board as to her qualifications and training as a nurse. The second will be the fixing of a proper standard of training for nurses, ensuring that those whose training does not come up to this standard shall not be permitted to enter for the examination which admits to the register.

The honorary secretary of the Irish Nursing Board (Miss Carson Rae), in replying to the question of the secretary of the College of Nursing, Limited, why the Irish nurses should not throw in their lot with the latter body, states (1) that the council of the Irish Nursing Board has been elected not nominated; (2) that Irish nurses object to the College of Nursing on the grounds that it is a limited liability company, with memorandum and articles of association subscribed by seven laymen, who nominated the first council which framed the rules for the nursing profession; (3) that the College of Nursing proposes to issue two kinds of certificates (a) certificates of proficiency; (b) certificates of training and proficiency, thus mixing up trained nurses with other women workers in hospitals, to whom also they propose to grant certificates.

THE work of the Subsidiary National Health Board, supported by the New York Rockefeller Foundation for the eradication of hookworm, has, in co-operation with the Government, been extended to eight Southern States and fifteen foreign countries. The new fields of operation were Salvador, Brazil, Ceylon and Siam, and early in 1917 work was begun in the Fiji islands, Papua, and Queensland (Australia).

Correspondence.

HOW IS THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS TO BE MADE?

SIR,—A communication from the Halifax Insurance Committee has been received this week by the local panel practitioners, referring to the diagnosis of pulmonary tuberculosis; in it we are informed that they are of the opinion "if only cases of tuberculosis were notified in their early stage and application made to the Insurance Committee for Sanatorium Benefit, better results could be obtained," and then, "since the inception of the National Health Insurance a large number of insured persons in an advanced stage have applied for sanatorium benefit . . . and they feel that the time has come when it is essential, *if any good is to be obtained*, that they must have cases in their earlier stages." (The italics are mine.) As a supposed assistance to us, there is enclosed a memorandum by Dr. Sutherland, tuberculosis officer to the Manchester Insurance Committee.

One may not appreciate the evident desire of an Insurance Committee to act as literary advisers to the faculty, or the, possibly unintentional, insult to our medical training; but, those on one side, the communication and memorandum certainly call for comment.

In regard to the memorandum, I do not know how far it satisfies the wish of those Manchester practitioners mentioned in the memorandum who have expressed a desire that they should be helped to recognize cases of tuberculosis at an earlier stage than at present. It certainly does not satisfy mine. If we exclude the modern methods of diagnosis, which we are assured are of little value, the memorandum consists mainly of a description of the physical signs which can be obtained in any textbook of the past century, and there are the same generalities when describing those earlier complaints which may be all-important in the answer to the question, How can we recognize at an earlier stage than at present cases which are developing pulmonary tuberculosis?

There is now among panel practitioners a well-established feeling that the sanatorium benefit under the Insurance Acts is a failure. The routine treatment appears to be: The patient applies for sanatorium benefit. (In early or advanced cases the result is the same.) After a period ranging from one to two months (it may be different in other districts, I am writing of what I know) the patient is granted eight weeks' sanatorium benefit, usually extended to twelve. He is then discharged, looking better, and the physical signs usually pointing to some slight improvement. He is then placed on domiciliary treatment, and does his best to try and live on 10s. a week. Very soon, however, he returns to his former employment, and *ipso facto* ceases to visit at the surgery. After a short period he again calls, and in a worse condition than the first time that he came under treatment, and he will not have anything more to do with sanatorium benefit.

The failure is now to be attributed to our lack of diagnostic power. That may be, but it is not due to carelessness or the lack of appreciation of the physical signs, as suggested by Dr. Sutherland. I can supply cases from my own practice where the patient was informed of his illness the first time he called at the surgery, with no history of previous visits, and cases extending over several years where the condition was suspected and the patient repeatedly examined (stripped to the waist, as Dr. Sutherland suggests), and no physical sign was revealed, and then the end coming like a thunderclap. But what perhaps is even more deplorable, I am at present attending a boy of 17 suffering from tuberculous ulcers of the leg, whom I advised after his discharge from the local infirmary four months ago to apply for sanatorium benefit, but he was refused admission because they "do not treat surgical cases at the sanatorium." So his mother informed me, and, in view of the lapse of time, I expect the statement was correct. He was granted domiciliary treatment—eggs and milk, and a fortnightly visit by a nurse. His leg is improving, but (and most of us would watch for this) the first faint signs of pulmonary involvement are appearing. If past experience is any guide, his chances of recovery now are as good at home. And the Insurance Committee writes us to ask for earlier notification, and encloses a memorandum.

Dr. Sutherland states in his memorandum that in some cases the patient seeks medical advice for anaemia, gastric trouble, morning cough, persistent tiredness and languor, repeated colds, loss of weight, and suggests that if these are carefully examined pulmonary lesions may be found. That is true; but what he may not know is that the most careful examination may fail to find the lesion, and it is only after the patient has come many times for these apparent trivial complaints that the lesion presents itself in an early stage. What is the significance of those earlier complaints?

The whole subject is full of difficulties which only a general practitioner can appreciate. For example, I saw at least a thousand insurance patients last year in whom the complaint was of those indefinite symptoms mentioned; a few of these had tuberculosis, and a certain number of them may have had that irregular temperature mentioned as a valuable diagnostic sign—but how was I to gain that information? Anyone can make such statements in books. If someone would tell us from his own practical experience in general practice how it can be accomplished, it would be of some service.

Insurance practice has many discouragements, but it appears to have opened up a new field of medical research, and many of the problems which now confront us in the need for earlier diagnosis of most diseases may yet be solved. But in that field of research the general practitioner will be little benefited by the irresponsible comments of a lay committee or the condescending advice of the so-called specialists, who seem to be as ignorant of the subjects as we are ourselves.—I am, etc.,

Halifax, Nov. 16th.

A. GARVIE.

PRIMARY EXCISION OF GUNSHOT WOUNDS OF THE ELBOW-JOINT.

SIR,—I have read Lieut.-Colonel Mansell Moullin's article on primary excision of gunshot wounds of the elbow (BRITISH MEDICAL JOURNAL, November 3rd, p. 583) with great interest, particularly as he entirely supports the view I put forward in a paper advocating primary excision of the elbow-joint for severely infected gunshot injuries, read before the Surgical Section of the Royal Society of Medicine on March 14th, 1917. In this paper (published in full in the *Transactions* of the society, and in the *Lancet* of April 7th, 1917) were given notes of eight cases in which I had performed primary excision of the elbow-joint for extensive gunshot injuries complicated by fracture of the articular ends of the bones and by sepsis, and since that date I have operated upon five more. Of these thirteen cases the result in ten was most satisfactory, a free range of movement with good muscular power being obtained; in two the range of movement was limited to about 45 degrees from the formation of callus around the sawn surface of the bones, whilst the remaining case required subsequent amputation through the arm for the spread of sepsis in a highly infected wound.

Colonel Mansell Moullin apparently bases his opinion on the results of five cases of excision performed for injury in civil practice, conditions which are not strictly comparable with those of gunshot injury in the present war. In the latter there is much more comminution of bone, small fragments being forcibly driven into the surrounding tissues by the impact of the missile, whilst the infection with anaerobic and aerobic organisms rapidly spreads in the lacerated muscle planes. However, as he points out, the operation of excision permits of free drainage, and the adoption of frequent irrigation by which sepsis is controlled, whilst the operation materially shortens the period of convalescence, and gives the patient a chance of a freely movable joint with good muscular power in place of a joint ankylosed in such a position that its utility is much impaired, and in which healing is only obtained after a long interval, and frequently then only after several operations for sepsis, or for the removal of necrosed fragments of bone.

Colonel Mansell Moullin emphasizes the point that sufficient bone should be removed. I prefer to resect the humerus just above the epicondylar line, and the ulna and radius at the level of the neck of the latter, leaving an interval of two inches between the sawn surfaces when the limb is fully extended. The actual line of resection must, however, depend to a certain extent upon the conditions present, particularly the lines of fracture in the

lower end of the humerus, from which too much must not be removed for fear of a flail-joint remaining; in one case I divided the humerus three-quarters of an inch above the upper limit of the olecranon fossa, but only removed the olecranon through its base, leaving the coronoid process of the ulna and the whole of the head of the radius intact, with an excellent result. As much as possible of the comminuted fragments of bone driven into the tissues should be removed, as these may cause trouble from subsequent necrosis or from foci from which ossification may occur and limit the free movement of the joint. In my earlier cases I used at the most two sutures to approximate the ends of the incision, leaving the remainder open for free drainage and irrigation, but in the more recent cases, after checking the oozing with hot saline and treating the area with spirit, I have smeared the surfaces with bipp and closed the wound with a few deep sutures.

Colonel Mansell Moullin suggests that these primary excisions should be performed at the casualty clearing stations. Whereas theoretically this might be an advantage, in that the operation would be performed before the infection became marked, the extent of the damage to the bones and to the joint must be first ascertained by thorough radiographic examination, etc., which could hardly be done when a rush occurred. Further, I feel that the after-treatment of the case is of equal importance as the operation, and that both should be under the eye of the operator if possible. Care must be taken by appropriate splinting to prevent any inward displacement of the bones of the forearm upon the lower end of the humerus, and passive movements should be commenced as soon as the wound permits of it.

I cannot too strongly urge, with Colonel Mansell Moullin, that if primary excision of the elbow-joint was performed for severe gunshot injuries involving the articular ends of the bones, we should put the wounded man in a better position for earning his future livelihood, would materially decrease his pain and shorten his convalescence, as well as save the State much of the expenses of prolonged hospital treatment.—I am, etc.,

R. H. JOCELYN SWAN, M.S.Lond., F.R.C.S.,

Major R.A.M.C.

Senior Surgeon, Royal Herbert Hospital, and Consulting Surgeon, Woolwich District.

SIR,—I can heartily endorse Colonel Mansell Moullin's advocacy of excision of the elbow in gunshot wounds involving the joint, when, as he says, "the wound becomes septic, and the bones are badly comminuted." Three cases of excision have been under my care in Exeter during the last two and a half years. Two were excised by Mr. Marmaduke Sheild, and the results were excellent. The wounds healed readily, and the joints were freely movable and strong. The third case was lately excised in France, and is promising equally well.

During the same period I have had charge of three excisions of the shoulder. Two were done by Mr. Marmaduke Sheild and one at the front. The results were less impressive, as in two cases the deltoid was paralysed by the original injury. As an operation, however, it appears to me of nearly equal value with excision of the elbow. Well-controlled movement is obtained in certain directions, and healing is comparatively uncomplicated. The arm is much more useful than if allowed to ankylose at the shoulder, recovery is easier, and the patient takes a more hopeful interest in its progress.—I am, etc.,

Clyst St. George, Devon, Nov. 19th.

D. W. SAMWAYS.

A MINISTRY OF HEALTH.

SIR,—In your leading article of October 27th on the bill for the constitution of a Ministry of Health recently drafted by organizations interested in health insurance you state that "the position of the approved societies is fully and amply safeguarded." This is true, and I think it requires to be more strongly emphasized that the bill under consideration is an effort to retain and amplify power already in the hands of lay officials associated with insurance. You rightly indicate that the interests of the medical profession are not sufficiently safeguarded.

The approved societies, in a sense, represent the health interests of the working class, but not necessarily its corporate opinion on social and economic problems, and it

would probably be safe to say that the promoters of this bill were expressing the views, not of labour, but of those with interests vested in insurance. Labour is organized in different ways for different purposes. For an expression of the most advanced thought on industrial problems of the present day the medical profession would be well advised to watch the modern trade union movement, for it may have lessons for us. It aims at self-government of industries by the workers. The trade unions in congress have adopted this policy, which is seen in its most highly developed form in the propaganda of "national guilds" toward the conduct of industry and public service generally on democratic lines, for the benefit of the State, by those who do the work.

If we apply the idea to medicine, we can conceive a medical service organized for the benefit of the State, but administered and conducted by the medical profession, and something of the kind is the only form of State service that the profession should countenance.

Admittedly this ideal is a long way from attainment, but the imminent reorganization of sections of the health services may bring it nearer if the profession applies the weight of its influence in the right direction at the proper time. The essential thing is that we should know what we want, and that we should not want something which the electorate, and particularly the wage-earning majority, will not let us have. It is clear that the laity is out for a State service sooner or later and that if the profession is intransigent the trend of legislation will be toward wider development of the present whole-time services and consequent narrowing of the field of general practice. It means ultimately a State service coming after the gradual growth of a department or departments has created and entrenched powerful vested interests which are not those of the profession generally. Are we not told by Lord Rhondda that the requisite condition for a Ministry of Health is "that the Local Government Board and the National Health Insurance Commissioners should come to an agreement"? (BRITISH MEDICAL JOURNAL, November 3rd, 1917, p. 588.) Is either of these bodies greatly concerned about the status of the medical profession?

The Association appears to be alive to some of the dangers, but for a remedy to pin its faith on the creation of an Advisory Board to guide the footsteps of the new Minister. It is certain that such a board would carry little weight. I believe that the profession would strengthen its position if it went "all out" for radical reorganization of all the relations of medicine with the State and with local representative bodies. For health purposes power might be vested in local boards of health of the personnel of which the profession would form one-half. The medical representatives would be appointed by their local brethren and would constitute the only medical advisers to the boards, forming executive committees to carry out their policy.

The carrying out of national policy and the control of local boards might be the functions of a Central Board of Health, the medical members of which, forming half its personnel, would be appointed from local medical representatives by the medical profession, either meeting in congress or in some other way. The Minister of Health would be the chairman and the link between Parliament and the board.

Some such scheme, I believe, would not be opposed by the bulk of the profession if they once realized that the alternative is gradually increasing lay control of the kind they have experienced in panel practice. I do not think that labour would resist very strongly, if its adequate representation on the local and central boards was ensured and the profession showed itself sufficiently enlightened to recognize similar organization of the wage-earning employees who would form so large a part of the staffs of expanded health departments—for example, nurses and clerks. In future, the opposition or support of labour is an important matter for us.

It may be said, as it was said at a recent meeting of the Medical Guild in Edinburgh, that we ought to commit ourselves to no scheme till the men on service return. It does not appear that Government departments or insurance societies and committees will be actuated by any quixotic regard for the interests or opinions of the profession in the army. Moreover, it may be answered that reorganization is a solution of the very problem of medical

demobilization to which you devote your leading columns of November 3rd.

Would it not meet the need for an expression of corporate opinion if the Association circularized all medical men, on service or otherwise, asking for specific answers to three questions, which might be put thus—

1. Will you oppose a State Service on any terms?
2. Do you favour a service resembling in organization the Civil Service or the Indian Medical Service?
3. Would you approve of a service in which the local and national interests of the profession were safeguarded by adequate representation on local and central governing bodies, the medical representatives being appointed by the profession?

The opinions thus obtained would enable the Association to face the insidious introduction of bureaucracy in medicine with a policy which would be based on the views of the profession as a whole. If we do not control the present movement we shall drift into a State service in which the control will come from above, where the profession's own representatives will not be found. Speaking in Parliament on November 1st, Sir Eric Geddes said, "The theory underlying my reorganization of the Board of Admiralty has been to decentralize but at the same time to strengthen the control of the Board over the business of the Admiralty as a whole." The position of the Board of Admiralty—an executive board largely expert—and the policy of its new head might be taken for an example by us.—I am, etc.,

November 5th.

CONTROL.

LAY RADIOGRAPHERS AND ELECTRO-THERAPEUTISTS.

SIR,—The Medico-Political Committee of the Association is to be congratulated on having taken up the subject of lay radiographers and having recommended that the practice of radiography by unqualified persons "ought not to be encouraged." I would go much further and would suggest that the practice of radiography by laymen be made a penal offence, and that laws be passed which will render it impossible for the practice of radiography to be carried out by other than skilled and trained medical experts. The war has called into existence hundreds of assistants, both male and female, in the x-ray departments of the numerous war hospitals, both at home and abroad. Many of these were, prior to the war, absolutely ignorant of the elementary details of x-ray technique, and as a rule they were chosen to fill the posts because they had had some experience in photographic developing and printing. After the war many of these assistants will no doubt try to practise radiography on their own account. The same remarks apply to those who are now applying electricity for medical purposes, and unless steps be taken to prevent such practice we shall, after the war, have thousands of men and women setting up as experts, with the result that these valuable diagnostic and therapeutic agencies will fall into the hands of unqualified persons, to the detriment of the public at large.

As assistants to radiographers and electro-therapeutists these persons will serve a useful purpose, but, beyond the small number which will be required, it should be plainly made known to them that they will stand no more chance of earning a livelihood from the knowledge they have gained during the war than a private in the Royal Engineers will have of setting up as a consulting engineer. In the x-rays we have a power which, if unskillfully used or used with malice, may be productive of the greatest possible harm, and on occasions may even cause death. The fact alone that sterility can be brought about by their agency is sufficient in itself to warrant the passage of laws to prevent their being used at random. I am sorry to have to admit that the necessity of restrictive laws has been largely brought about by the actions of unthinking members of our profession. Prior to the war there were many x-ray departments, especially in small and country hospitals, where x-ray treatment was administered by lay assistants under no medical supervision, and I am still more sorry to have to admit that in a few of our war hospitals the x-ray departments are entirely run by laymen whose diagnostic reports are accepted by the medical and surgical staff. I do not think that this is done with the full cognizance of the War Office, but the fact that such a state of affairs exists is sufficient in itself to prove that the physicians and surgeons concerned do not or will not recognize that the practice of radiography and electro-

therapeutics are legitimate branches of professional work. Now is the time to take decisive steps, and I trust that those interested will not leave a stone unturned to rid us of the dangers which threaten us.—I am, etc.,

November 19th.

J. H. E.

VENEREAL DISEASE AND BLINDNESS.

SIR,—In the concluding paragraph of a note on the welfare of the blind, on page 592 of your issue of November 3rd, it is assumed to be erroneous to say that 50 per cent. of all blindness is due to venereal disease, and the writer suggests that such a statement may be made use of "by persons who do not trouble to verify their references, to make a mischievous and unwarranted reflection on the blind."

It would be interesting to know upon what evidence this view is based. The relation of venereal disease to blindness is as difficult to ascertain from statistics as its relation to the death-rate (see Osler, Lettsomian Lecture, 1917). Statistics as a general rule do not state the actual cause with sufficient exactness. The almost negligible amount of blindness from trachoma and small-pox in this country renders most Continental statistics to a great extent valueless for purposes of comparison. It should also be remembered that venereal diseases shorten the lives of their victims, so that the accumulation of the venereally blind is retarded, and a certain number of these cases never come to be included in any returns.

Owing to this tendency of venereal subjects to die, to the occurrence of other forms of blindness, and to the varying incidence of ocular manifestations of venereal disease in the successive decades, the proportion of venereal blindness to other blindness varies considerably. In early infancy it must be very high, and in spite of the action of the factors mentioned the appalling proportion of 58.35 per cent. is still present (Harman) in blind schools. After this age accidents as a cause of blindness become more important, and in successive decades the amount of non-venereal blindness increases. But syphilitic eye conditions only reach their maximum in the third and fourth decades, and are responsible for many cases of optic atrophy and other conditions which check the decline in the venereal proportion. Venereal subjects now tend to die out, and amongst the very old blind there must be few whose blindness is of venereal origin. Could corrected statistics be obtained, altered so as to give subjects of venereal blindness the average lives of other blind persons, some light might be thrown on the true relationship of venereal disease to blindness, and a 50 per cent. estimate might turn out to be not unduly high.

With regard to the final sentence of the article in question, may one express the hope that, in this more enlightened and, we trust, more charitable age, we shall all be able to divest ourselves of the old attitude towards venereal diseases, the attitude which associates a stigma and a reflection on the unfortunate sufferers, and has all along been the real obstacle to remedial measures either preventive or curative? The success of the present antiveneral campaign depends very largely upon the extent to which this attitude can be got rid of. To designate as venereal disease, whether mistakenly or correctly, the cause of blindness in any case should be no more considered to imply a reflection than if any other diagnosis had been made. Hitherto patients have been too often "accused of" or "taxed with" venereal disease which they in turn "denied" or "admitted." Such expressions are not used in connexion with other diseases. Prudery, reticence, and affectation have signally failed; our faith must now be pinned to sympathy, candour, and thoroughness.—I am, etc.,

Edinburgh, Nov. 13th.

H. M. TRAQUAIR.

* * The paragraph to which Dr. Traquair refers criticized a misquotation. The *Report* of the Departmental Committee on the Welfare of the Blind stated, on the alleged authority of the *Report* of the Royal Commission on Venereal Diseases, that over 50 per cent. of all blindness was due to venereal disease. Reference to the cited paragraph of the latter report showed that the figures concerned children alone. Neither the *Report* of the Departmental Committee nor that of the Royal Commission gave any data as to the part played by venereal diseases in the production of blindness at all ages. Against

the arguments and conclusions set out by Dr. Traquair may be set the following: Of the cases of blind children in Mr. Harman's list 31.3 per cent. were certainly, and, in addition, 2.8 per cent. probably, due to syphilis; 24.35 per cent. were due to ophthalmia neonatorum. In adults there are no gonorrhoeal forms of blindness comparable in frequency with ophthalmia neonatorum. Of syphilitic blindness uveal effects and optic atrophy may or may not be comparable in children and adults, there is no sufficient evidence either way; but interstitial keratitis, so prolific a cause of blindness in the inherited syphilis of children, is a rare cause in the acquired syphilis of adults. On the other hand, cases of accidental blindness are few in children and many in adults. Similarly, blindness from glaucoma and cataract heavily weight the scale for adults. Finally, it is unsafe to argue from data gathered from children under 16 years of age to all ages, for blind children of this age group form but a small part of the total of the blind (about one-twentieth). An attitude of frankness in dealing with the causes, prevention, and treatment of venereal diseases does not affect the objection to an erroneous quotation which we have reason to believe will give pain to the blind.

TREATMENT OF WAR NEUROSES.

SIR,—At a large conference of neurologists which recently met at the War Office a scheme in which I am interested was rejected.

My scheme, now known as the "Country Host Institution," was originally intended for the benefit of pensioners, and the Ministry of Pensions and the London War Pensions Committee have sanctioned it experimentally to the extent of thirty cases. Half that number of pensioners have already been sent off, and the early reports are very satisfactory.

I sincerely hope that the conference may yet consider my scheme, for I have every reason to believe that the patriotic hosts on whom its success must depend could be found in very large numbers.

Medical experience and common sense agree that (1) country life and conditions tend more towards the cure of neuroses than the noise and rush of towns, and that (2) nervousness is extremely communicable. If these premisses are admitted, a very little thought should be sufficient to convince every unbiassed person, whether neurologist or layman, that it is wrong to congregate nerve-shattered men in hospitals, unless the severity of their symptoms renders in unavoidable, and that it is unpardonable to keep even those serious cases in a town, especially in London, where air raids are frequent.

It seems obvious that, however convenient for the authorities, it is exceedingly harmful to the men that they should be congregated, the mild along with the severe, and perhaps within an air-raid area. The following extract from a letter sent me by Archdeacon Dray will give an experienced eye-witness's impression of the effect of air raids on nerve-shattered men:

Last night we had a repetition of former experiences in these schools, where 200 men in varying stages of helplessness act and react upon each other day by day, and during the raids are nearly frantic with terror, numbers of them writhing under their beds or falling back into their former palsied condition, their eyes transfixed and their twitching faces wearing a look of abject horror. It is pitiful to hear their repeated appeals: "Why can't I go into the country, somewhere where it is quiet and restful? Is a man who has gone through what we had at the front to be kept in this hell until he loses his reason," etc. The nurses are simply splendid in their calm bravery, but I seriously wonder how long some of them can stand the spectacles presented.

The ideal treatment, for all the milder cases at any rate, is to send them singly to the country, where they may recuperate in peace and quietness, performing suitable tasks in the open air and with healthy mental influences round them. The Country Host Institution could send over 200 men to excellent country houses within a week or two.

It will very greatly further the views expressed above if any medical men who are in sympathy with them will communicate with me.—I am, etc.,

THOMAS LUMSDEN, M.D.

13, South Eaton Place, Belgrave Square,
S.W.1., Nov. 19th.

THE REMUNERATION OF RURAL PRACTITIONERS.

SIR,—I was pleased to see in the *BRITISH MEDICAL JOURNAL* of November 10th the letter from "A Country Doctor," also your article on the subject.

My experience is much the same; before the war my practice was doing some £1,100 per annum *gross*, now the receipts are below £600 and the expenses as large as formerly. Decreased panel list, owing to enlistments and removals to munition areas and retrenchment by the better-class patients, help to account for this. I find it means greatly lessened receipts, very little proportionate decrease of expenses (actually they are not decreased at all, owing to rise of prices).

"A Country Doctor" is most conservative in his estimate of the expense of attending the discharged soldier. I do some 12,000 miles per annum by car; before the war the cost of running a car was at least 5d. per mile, now it is considerably more, even for the smallest light car. Standing charges, such as depreciation and licences, should be reckoned when counting cost per mile, to get a fair estimate.

Perhaps now that the rural practitioner is waking up a little we may gradually get some attention drawn to the conditions in the country. The town doctor may take some scattered country houses round into his net, but he does not show much eagerness to take a panel patient three miles from anywhere, the last mile or so perhaps across fields; the country doctor must accept all in the district.

Rural practitioners are usually much in the minority at all British Medical Association meetings, and also on local committees; as, under present conditions, payment for mileage would mean less for the town members, how can we hope to carry the point?—I am, etc.,

November 19th.

ANOTHER RURAL G.P.

THE CURE OF INGUINAL HERNIA.

SIR,—Nearly two years ago I had the privilege of seeing Lieut.-Colonel Hull operate on several cases of hernia, and I was much impressed by the simplicity of the operation and the excellence of the immediate results. To me the technique was quite new.

From the experience gained by operating on some hundreds of patients by this method I can fully corroborate what Lieut.-Colonel Hull says about the advantages of his operation in the vast majority of cases. Very seldom indeed was there any delay in finding the sac, and once found there was no difficulty at all in ligaturing it high up.—I am, etc.,

Newbury, Nov. 12th.

W. B. HEYWOOD.

SIR,—I do not wish to appear unappreciative of Colonel Hull's technique, but when he says "the essential principle is that the sac is not dissected out, it is merely incised, and the peritoneum is grasped from within the sac at the level of the internal abdominal ring," I cannot agree with him as to his interpretation of his own operation. The level of the internal ring cannot be reached without pulling down the sac after he has cut it across. Colonel Hull really does this by blunt gauze dissection outside the sac.

I would suggest that Colonel Hull is mistaken in his idea that he originally grasps the sac at the level of the internal abdominal ring; for the latter is covered over by the fibres of the internal oblique.

I should be sorry to accept Colonel Hull's condemnation that other operations (and operators) end at the point where he begins, for my sole contention was that the whole sac should be removed. This can only be done with certainty by pulling down the sac until a collar of extraperitoneal fat appears around it. This shows that the parietal peritoneum has been reached. Ligation below this point would assuredly leave a small portion of sac, and the operation would be useless.

The essential principle is that the whole sac should be removed.—I am, etc.,

London, W., Nov. 18th.

JOSEPH CUNNING.

RECURRENCE OF ADENOIDS AND TONSILS.

SIR,—It is pleasant to learn that Dr. A. M. Barford takes such a rosy view of the results of operative treatment of nasal obstruction in young children.

¹BRITISH MEDICAL JOURNAL, November 17th, p. 672.

Daily work in a tuberculosis dispensary exhibits children of all ages whose chests do not bear witness to successful results of surgery of the septum and turbinates. But operations on young people over 16 years of age, and on cases of military age referred for examination, have shown encouraging results in the shape of reduced number of attacks of nocturnal dyspnoea and generally improved respiratory function.

Apparently heredity plays such a prominent part that several generations must pass after the operation before the final disappearance of this deformity, which produces such unfortunate results, and does the mischief, as the sower of tares, while folk sleep.—I am, etc.,

Newport, Nov. 18th.

J. LEWIS THOMAS.

Obituary.

EDWARD BURD, M.D., M.C.CANTAB., J.P.,
SHREWSBURY.

On November 15th, at Newport House, Shrewsbury, died Dr. Burd, in the 91st year of his age. He was born in 1826; was educated at Shrewsbury School under Butler; at Caius College, where he was Tancred student and Caius scholar; and at St. Bartholomew's Hospital. He was a son of Henry Edward Burd, F.R.C.S., of Shrewsbury. He took his M.B. in 1851, his M.D. in 1859, and his M.C. in 1863. He was the first man in England to be examined for, and to receive, the degree of Master in Surgery; and was afterwards an examiner for that degree in Cambridge. He was on the staff of the Salop County Hospital for more than half a century—many years on the visiting staff, afterwards on the consulting staff. By right of age his name was first on the roll of burgesses, and first on the lists of Shrewsbury School; and he was one of those remaining officers of the Volunteer Corps, commissioned in 1859–60, who were presented to King Edward VII in 1910. He was twice married; his wife, and his family by his first marriage, have outlived him. He was buried at Shrewsbury on November 19th. All Shrewsbury had been proud of him, and was in mourning for him.

He was, indeed, a great physician; he had not only profound experience, but insight, judgement, and wisdom: he had to perfection that incommunicable power of "looking at a case all round," which seems, in men like him, so natural that foolish people call it intuitive or instinctive. In the exercise of his incessant practice he was honourable and he was generous. But a man may have all these gifts, yet fail to make every stroke of his work tell; he may lose some of his effectiveness by unmethodical habits, or by undue self-effacement, or by a mere trick of levity or solemnity. Dr. Burd was of stronger temperament. His influence and his authority were in everything that he did or said; he was not afraid of anybody; he won the confidence of his patients by masterful sincerity and plain speaking.

He would have made his mark in London; it is probable that he would have been one of the foremost of London consultants; and for some years of his life he used to wish that he had chosen this path to success. Perhaps, in the long run, he would not have been happier. For his name became a household word, far and wide, not only in Shrewsbury but throughout the county, and beyond. He was the recognized head of his profession in that part of England, and he lived to be, as it were, the Father of the Town, its oldest and most honoured representative. He had been president of the Shropshire and Mid-Wales Branch of the British Medical Association. He worked hard, both at the Salop Infirmary and in civic affairs, to promote many good plans for the public welfare; and he was, especially, a zealous guardian of that very beautiful church, St. Mary's, Shrewsbury. For ninety years Shrewsbury had been his one and only home; and by the time that he was an old man he had drawn to himself, in a very remarkable way, the love and the admiration of men. In the earlier years he had built up and maintained, by incessant toil and indomitable will, his great practice, beginning with what was left of his father's practice. He had been associated in work with Mr. Henry Fenton, and later with Mr. H. J. Rope: but he had of himself borne such a burden of work as some of us could hardly tolerate. Now and again, in those impetuous

years, twenty years without one real good holiday, he showed a touch of hardness in his temperament, a touch of intolerance. In the later years, in the years which bring the philosophic mind, and bring to some of us something which may be even better than philosophy, he steadily gained and held the gifts of patience, faith, and gentleness. He had his full share of troubles: none the less, or all the more, he attained that height at which a man is able to face and to solve the problem of old age, the problem which is left to the very end of life because it is the most difficult of all. In his last illness he had much to bear, but he bore it with courage and humility. "Nothing but well and fair, and what may quiet us in a death so noble."

THE death, as the result of a motor accident, of Professor DASTRE, has deprived France of one of its most eminent physiologists. He was born in 1845, and it was not until after he had had a thorough grounding in embryology and comparative anatomy that he entered the laboratory of Claude Bernard in 1872. Being convinced that a physiologist ought to have a knowledge of medicine he carried on medical studies at the same time as laboratory researches. His earliest researches concerned the action of the sympathetic in producing vaso-dilatation; later he gave special attention to nutrition in connexion especially with the function of the liver and the absorption of fats. He made important researches on immunity and anaphylaxis also. In 1876 he took the place temporarily of Paul Bert as professor of general physiology at the Sorbonne, and in 1887 succeeded to the chair. He became a member of the Academy of Sciences in 1904, and of the Academy of Medicine in 1908; for the seven years preceding his death he was president of the Society of Biology. Dastre was not only a diligent and successful experimenter, but a great teacher, and many of his pupils now hold important positions. He was master of a fine literary style, and did much to make known the advances of physiology to the intellectual classes by his articles in the *Revue des Deux Mondes* and the *Revue philosophique*.

THE death of Mr. GEORGE BROWN, M.R.C.S., removes one who was for many years a keen participant in medical politics, and an industrious worker on behalf of various professional reforms. He was born in 1844 at Callington in Cornwall, and late in life he returned to the place of his birth. As a student of Charing Cross Hospital he obtained the Golding and Llewellyn scholarships, and a gold medal in 1873, the year in which he qualified. He then served in succession as house-surgeon to Charing Cross Hospital, demonstrator of anatomy at the Westminster Hospital Medical School, prosector of anatomy at the Royal College of Surgeons of England, and resident medical officer at the North-Eastern Hospital for Children. Mr. George Brown had a ready pen. In the Seventies he published several small works for students, and these were followed at intervals by a number of papers contributed to medical journals. From 1897–1907 he served as direct representative for England on the General Medical Council, and interested himself in various matters affecting the position of general practitioners. For many years he was a member of the British Medical Association, and was a familiar figure at the annual meetings, taking an active and prominent part in the political discussions. He found further outlets for his large store of energy in the editorship of the *Medical Times*, and in the affairs of the Imperial Medical Reform Union, of which he was general secretary and part founder. His death will be regretted by a wide circle of colleagues and friends.

DR. THOMAS AHERN SHEAHAN, of Attercliffe, Sheffield, died on November 2nd, in his 53rd year, after an operation for acute appendicitis. Dr. Sheahan was the third son of the late Timothy Sheahan of Drinagh, Buttevant, co. Cork. He was educated at St. Colman's College, Fermoy, and studied medicine at the old Queen's College, Cork. Thence he proceeded to Dublin and obtained the diplomas of L.R.C.P. and L.R.C.S.I. in 1888. Shortly afterwards he settled in Sheffield, where he practised for twenty-eight years. Dr. Sheahan was a man of fine physique (his height was 6 ft. 3 in., and he was one of a family of ten, who averaged over 6 ft.), and a fluent speaker; at the time

of his death he was president of the Attercliffe Medical Guild. He took an active interest in local affairs, built model workers' dwellings, and was zealous in alleviating the hardships of Belgian refugees. To the last he was a strenuous worker against what he deemed the enslavement of his profession by the National Insurance legislation. His keen interest in the affairs of his native country never flagged, and he was connected with many Irish societies in the city of Sheffield. More than thirty of his medical colleagues paid a last tribute to his memory by their presence at the graveside, including his life-long friends, Dr. P. Bennett and Lieut.-Colonel Sinclair White. There were also delegates from friendly societies, and a great gathering of relations and friends. He leaves a widow and four daughters.

We regret to announce the death, at the age of 43, of Dr. J. RAMBOUSEK, Professor of Factory Hygiene, and Chief State Health Officer, Prague. He was recognized as one of the leading writers and workers on factory hygiene on the Continent, and it was noteworthy how ably he seemed to combine the duties of professor, inspector, and laboratory worker. His industry in collecting material for anything about which he wrote was remarkable. He was best known by his book *Gewerbliche Vergiftungen*, which was translated into English, and published by Edward Arnold in 1913 under the title of *Industrial Poisoning from Fumes, Gases, and Poisons of Manufacturing Processes*. In 1911 he made a short visit to England, which he much enjoyed, leaving behind him the impression of a delightful personality.

Universities and Colleges.

UNIVERSITY OF LONDON.

The following candidates have been successful at the examinations indicated:

THIRD M.B., B.S.—Bertha Hinde, *A. E. P. Parker (University Medal), A. L. Abel, F. M. Alchin, Hannah K. Alton, Elizabeth L. Ashby, R. T. Bailey, Majorie A. Blandy, Marian N. Bostock, Margaret S. G. Bott, F. Caldecott, Hari Das, T. A. Davies, Phyllis D. Dixon, W. H. Dupré, K. R. Hill, H. M. Holt, H. C. Jennings, W. A. E. Karunaratne, W. H. Lloyd, B. Maclean, Sinnethamby Muttiah, M. H. Oldershaw, N. Olivier, Mariamne O. Ramsay, C. S. L. Roberts, K. M. Ross, H. Rowan, M. Schwartz, S. C. Shaw, Ellen Sylk, C. H. Warner, R. E. S. Webb.

B.S.—H. H. Greenwood.

* Distinguished in Surgery. † Distinguished in Medicine.

The following have passed in one of the two groups of subjects:

THIRD M.B., B.S.—Group I: Ruth Balfour, G. W. J. Bonsfield, P. S. Clarke, H. L. G. Foxell, Blanche A. Henderson, C. H. Marshall, Marie A. Moralt, A. Selby-Green, A. L. Telling, J. de S. Wijeyeratne. Group II: F. P. Bennett, L. B. Goldschmidt, D. J. A. Lewis, W. L. Thomas, Naomi Tribe.

UNIVERSITY OF EDINBURGH.

At a meeting of the University Court, on November 12th, Dr. W. G. Aitchison Robertson was appointed additional examiner in forensic medicine, and the professor of pathology was added to the Faculty of Science.

UNIVERSITY OF ABERDEEN.

The University Court, at its meeting on November 13th, agreed to adopt the federated superannuation system for such members of the university staff as were qualified to take advantage of it.

The Court has received intimation of a bequest by the late Dr. Archibald Carmichael, formerly of Barrow-in-Furness, and lately residing at Perth, of the residue of his estate, subject to certain life interests, "for the advancement of the work of the medical side of the University in such manner and subject to such regulations as the Senatus Academicus of the same University may from time to time determine and think fit." The value of the residue is understood to amount to £12,000. The wide discretionary powers given to the university in the application of the benefaction will make it the more useful.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The annual meeting of the Fellows and Members of the Royal College of Surgeons of England was called for November 15th, but on the Vice-President, Mr. Charters Symonds, C.B., taking the chair, a quorum was not present. After waiting the required fifteen minutes, and the numbers present still wanting half of the necessary thirty, Mr. Symonds declared that no meeting could be held. He added that as this was the second consecutive occasion on which an annual meeting had been called and a quorum had been unobtainable, it would be a matter for the Council to consider whether it would be worth while to

summon a meeting for next year in the event of the war continuing.

This was the first occasion for more than thirty years that the Society of Members, or the pre-existing body known as the Association of Members, had no resolution on the agenda.

The following have been successful at the examination indicated:

FIRST PROFESSIONAL EXAMINATION FOR THE FELLOWSHIP.—M. W. B. Bulman, Rustam Nusserwanji Cooper, Hilda T. Haggett, Edith M. Hall, H. L. Heilmann, O. S. Hillman, C. M. Ockwell, Dorothy Pantin, R. L. Rea, Esther Richards, W. G. D. Upjohn, J. Whittingdale.

Medical News.

THE late Dr. John Roberts Thomson of Bournemouth left £59,074 gross.

DR. WALTER HENRY POLLARD, J.P., Edgbaston, has been elected Mayor of the borough of Smethwick.

THE King has given £5,000 to King George's Fund for Sailors, and the chairman, the Duke of Connaught, £500. The fund now amounts to £210,000; the cost of collection has been only $\frac{1}{2}$ per cent.

FIFTY silver, eleven silver-gilt, and seventy-five bronze medals have been awarded to workers in the American hospital at Neuilly. Among the recipients there are thirty-seven men and ninety-nine women, mostly American.

THE usual Christmas bazaar arranged by Gamage (Holborn) will this year include woollen goods—socks, scarves, cardigan jackets, and gloves—for men in the navy and army, and also games and gramophones for men in hospital.

AT the meeting of the Royal Society on November 8th Professor A. D. Waller made a communication showing by demonstration that emotional response of the human subject is characterized (and can be measured) by alterations of the electrical resistance of the skin, independent of the well-known muscular and vasomotor and secretory manifestations of emotion.

A BRONZE mural tablet in memory of the late Dr. W. A. Haslam was recently unveiled at the Corporation Sanatorium, Cottingham, by the Lord Mayor of Hull. Dr. Haslam died on September 1st, 1916, from malignant scarlet fever contracted in the performance of his duties as medical officer of the Hull Corporation isolation hospital and sanatorium. An obituary notice appeared in the JOURNAL of September 16th, 1916.

THE report of the Yellow Fever Commission of the Rockefeller Foundation which sailed from New York on June 14th, 1916, and finished its work in South America in December of the same year, has recently been issued. The only endemic centre of the disease which the Commission could find at present was in Guyaquil, Ecuador. Certain South American countries are said to require close observation, and General Gorgas was appointed to direct this work, which, however, has been postponed in the meantime owing to the war.

AT a meeting of the West London Medico-Chirurgical Society on Friday, December 7th, papers on the methods of detecting simulated deafness and blindness will be read respectively by Mr. Richard Lake and Mr. Percy Dunn. Those who are expected to take part in the discussion of these papers are Mr. H. Tilley, Mr. Roxburgh, Mr. Mark Hovell, Mr. O'Malley, Major Goldsmith, C.A.M.C., Captain McCulloch (Toronto), Dr. Potter, and Captain Heron.

A CHAPTER of a strange story was opened at Bow Street Police Court on November 19th, when "Edward Yeates, describing himself as a medical practitioner and a captain in the New Zealand Medical Corps, surrendered to his bail to answer the charge of wearing military uniform without lawful authority." He is a medical practitioner whose name was entered on the *Medical Register* in 1886, and became a Fellow of the Royal College of Surgeons in Ireland in 1893. The magistrate ordered a remand until November 26th, and accepted bail. The facts will then, no doubt, be placed fully before the court. We may note that the accused denied the charge that he wore military uniform without lawful authority. He also stated that the notification in the *New Zealand Gazette* of July 22nd, 1915, which he produced, to the effect that "the notice dated January 28, 1915, relative to the appointment of Edward Yeates, F.R.C.S.I., is cancelled at his own request" was untrue. We believe that it will be shown that the appointment was not cancelled by his request, but that, on the contrary, he demanded an inquiry, which, we are told, was ordered but not held. We refrain from further comment for the present.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are:

1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Aitiology*, Westrand, London; telephone, 2531, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2530, Gerrard.

3. MEDICAL SECRETARY, *Mediscra*, Westrand, London; telephone, 2534, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC.

MR. NORMAN PATTERSON, whose paper on operations on the nasal sinuses appeared in the *JOURNAL* of October 20th, writes to say that in Fig. 1, printed on p. 514, the upper part of the diagram represents the anterior region of the nose and the lower part the posterior region. The figure ought, perhaps, to have been turned the other way up, as it is more usual for the anterior portion of the nose to occupy the lower part of such diagrams.

MR. GRIFFIN WILKES, M.R.C.S., medical examiner, White City, writes with reference to the scheme of examination to be followed by National Service Medical Boards, noted in the *JOURNAL* of November 3rd, p. 594, to suggest that it would be better to examine the heart and lungs first, as he considers the grading depends practically on this examination and the decision of the chairman.

Paton's List of Schools (2s.) for the current year contains a great deal of information with regard to public and private schools for boys and girls and other matters of interest to parents and guardians, including particulars as to fees.

A NEW ELECTRICAL STARTER FOR MOTOR-CAR ENGINES.

IN the *JOURNAL* of October 20th, p. 529, an account was given of a demonstration of an electrical starter for motor-car engines designed by the firm of C. A. Vandervell. It seems to have been generally assumed that the firm was in a position to meet orders for the starter, but we now learn with some surprise that it is unable to do so, the whole output of the apparatus being required in connexion with munitions contracts. Apparently it may be long before supplies outside these contracts will be available, possibly not until after the war is over.

NOTIFICATION OF BIRTHS ACT.

DR. JOHN ALCINDOR (Paddington), writes: A medical practitioner is compelled by law to notify to the M.O.H. of the county or county borough, without a fee, the birth of every child at which he is the accoucheur; should he fail to do so, after two previous warnings he is summarily convicted, and fined to a maximum of 20s. for each offence. If notification of birth is important and necessary—every thoughtful person fully appreciates its importance—surely it is worth paying for, even at the rate we are now paid for the notification of German measles. By such a show of justice and fair play the sense of oppression would be removed, and delinquents would pay their fines with equanimity. It is earnestly to be hoped that our representatives will direct their attention to this matter.

LANCISI ON SWAMP FEVERS AND THE MOSQUITO.

DR. LEONARD J. KIDD (London, N.W.3) writes: It seems to be little known, even by writers on malaria, that so long ago as 1717 Lancisi connected swamp fevers with mosquitos. Thus, I find, on turning to Gibson's *Textbook of Medicine*, 1901, vol. i, p. 290, that Sir Patrick Manson mentions, among the important steps in the history of malaria, Lancisi's investigations in its etiology, but refers to mosquitos only when writing of the work of Ross in 1898. Dr. John Foote, in an abstract on Lancisi in the *Johns Hopkins Hospital Bulletin* for October, 1917, states that Lancisi considered the possibility of infection by the bite of an infected insect causing "worms in the head," but admitted he could not prove this hypothesis. From the nature of these swamp fevers he was convinced of their connexion with mosquitos, and asserted that if swamp emanations are responsible they are and must be organized and living emanations. Lancisi's cure for swamp fevers was a system of drainage for the swampy lands, and also the planting of trees. It is probable that Dr. Foote is here referring to a long treatise of 350 pages entitled "*De Noxiis Paludum Effluviis eorumque Remediis in Genere*." It will be found in Giovanni Lancisi's *Opera Omnia*, Geneva, 1718. In Book I, chapter 16, on p. 46, culices (mosquitos) are

mentioned: he states that they deposit their eggs on stagnant waters. Chapters 17, 18, and 19 also contain much interesting matter. Certainly few persons will now deny that this famous old Italian man of genius is worthy to be held in everlasting remembrance.

ISOLATION OF CHOLERA VIBRIO AND OTHER ORGANISMS.

CAPTAIN HENRY WHITEHEAD, R.A.M.C. (E.E.F.), writes to place on record the fact that he had been for some time working on the same method as that described by Dr. Castellani in his paper published in the *JOURNAL* of October 13th, 1917, p. 476. The idea, Captain Whitehead states, occurred to him in February, 1917, but he had no opportunity of making experiments before the end of August. He hopes to be able to publish an account of his experiments and suggestions shortly.

ANAESTHETICS IN MILITARY HOSPITALS.

WITH reference to the remarks of Lieut.-Colonel J. F. W. Silk, in concluding the discussion on anaesthetics in military hospitals, reported in the *JOURNAL* of November 10th, p. 619, to the effect that the meeting was in accord with his condemnation of undiluted chloroform for routine use in military hospitals, Dr. John Brown (Blackpool) writes: About twenty-five years ago I published in the *BRITISH MEDICAL JOURNAL* a letter pointing out the comparative safety of giving chloroform by the slow and open method. I have practised this method for about forty years and I am satisfied that for the general practitioner (especially doctors in rural districts, who are often unable to have another doctor to assist), with chloroform given on a piece of lint in small doses for the first ten minutes, by which time the patient is calm and able to tolerate the chloroform vapour without any sense of suffocation, the dose may be gradually increased. The patient in a few minutes goes off quietly, without any violent struggling, and is perfectly anaesthetized. Usually it takes twenty minutes. The few minutes extra means comparative safety, no struggling; very rarely is there any vomiting. Deep narcosis is not necessary. When there is stertorous breathing the patient is in the danger zone and the chloroform should be stopped until this passes away. In my experience the slow and open method is comparatively safe. The quick method is not so safe and should be avoided. I believe some of the fatal cases are due to pushing the chloroform before the system has been gradually brought to tolerate it. The chloroform vapour is pleasant, non-inflammable, and does not increase the secretion of the salivary and mucous glands. In patients who have emphysema and are liable to chest affections ether is not desirable.

"COLLOSOL COCAINE."

MR. STROUD, writing on behalf of Crookes Collosols, Ltd., sends the following note: On May 5th last you published reports of Professor W. J. Simpson, Professor R. Tanner Hewlett, and Dr. John Eyre upon three series of tests made at King's College and Guy's Hospital with collosol cocaine, and these showed low toxicity coupled with satisfactory anaesthesia. This we attributed to the colloidal condition of the solution, but further investigation compels us to modify that conclusion.

Recently we have had the advantage of having collosol cocaine tested by Dr. Dale, of the Medical Research Committee, and he found that a considerable percentage of the cocaine used is no longer recoverable from the preparation, and doubt arises whether the alkaloid, as distinct from the protective, is present in the colloidal form. More probably the alkaloid is reduced to benzoyl-ecgonine and ecgonine, and collosol cocaine would now seem to exhibit a mixture of ecgonine, benzoyl-ecgonine, and methyl-benzoyl-ecgonine.

Our aim in preparing collosol cocaine was to produce a solution of cocaine which would give prolonged anaesthesia and at the same time would prevent too rapid diffusion, but we were entirely surprised at the remarkable absence of toxicity exhibited. This now appears to a large extent explained, since whilst the colloidal protective apparently adsorbs a portion of the cocaine, the remainder is found not to exhibit the attributes of a colloid, and, unlike the metallic collosols and those of iodine and sulphur, may be partially dialysed through a parchment membrane.

As we may in this respect have induced some error due to the complexity of the molecule, we trust you will see fit to publish this explanation and our appreciation of Dr. Dale's welcome investigation.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postae* remittances addressed either in initials or numbers.

Lectures ON THE ANATOMICAL AND PHYSIOLOGICAL PRINCIPLES UNDERLYING THE TREATMENT OF INJURIES TO MUSCLES, BONES, AND JOINTS.

GIVEN AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.
NOVEMBER-DECEMBER, 1917.

BY
PROFESSOR ARTHUR KEITH, M.D., F.R.S.,
CONSERVATOR OF THE MUSEUM.

I. THE ORTHOPAEDIC PRINCIPLES OF JOHN HUNTER.

Abstract.

IN my lectures for the present year I propose to review our stock of that kind of knowledge which is needed by the surgeon in the treatment of disabled men. There never was a time when we stood more in need of a ready knowledge of the right kind of anatomy and physiology than now. There are in our hospitals—our repairing sheds—thousands of human machines which have been damaged or maimed in the service of their country—awaiting or undergoing repair. We cannot restore action to any machine, much less that most complex of all machines, the human body, unless we know the arrangement and working of its parts. Whatever means or practices we adopt and apply for the treatment of these disabled men, there is one condition which must be fulfilled—they must be based on a knowledge of the structure and function of the body.

In this and in some of my subsequent lectures I propose to make excursions into the past, and cull from the lives of men who devoted themselves to the study of the human body such facts and experiences as may be of use to us at the present time. There are many reasons why I should begin with John Hunter: his life's work is the common inheritance of the Anglo-Saxon peoples; he was still in the full flight of his career when the United States and Britain parted ways; his career, as you know, reached an abrupt end as the winter session of 1793 began. It is not the stretch of intervening years, but the crowded series of revolutionary movements which have swept across the fields of surgery and medicine which make him seem distant to us. In his closing years came a knowledge of oxygen, of combustion, of respiration, of oxidation of the tissues, of heat and temperature—knowledge which threw much of Hunter's best work into the realm of pure history. Then later, in 1839, began the revolution of the microscope, which gave anatomists and physiologists their atomic theory. The result of that revolution was to make us think in terms of living cells; Hunter thought in terms of living structures, tissues, and organs. Then, finally, came the great Pasteur-Lister revolution: problems which Hunter had struggled to solve—problems of inflammation, infection, and repair—were finally fixed on a new basis of knowledge, and thus another section of Hunter's life's work lost its currency. The great evolutionary movement left Hunter's work unchanged; he was an evolutionist, but, fortunately for us, he studied the evolution of function rather than form. For medical men it is function rather than structure which matters. Hence it is that when we have deducted those parts of Hunter's labours which have been replaced by the progress of knowledge, there still remains a vast fund of permanent value not only for us now but for generations to come. I propose to pass in review only those parts of his writings which bear on the restoration of action to limbs and joints.

Were I asked to cite the most important contribution Hunter ever made to surgery, I would reply that it was his clear recognition of the fact that restoration is effected by powers inherent in the living tissues of the patient; the surgeon can only help recovery by tending these powers. This attitude towards disease keeps on recurring throughout his works. I shall quote only one instance. It is from a passage where Hunter speaks of the practice, followed by certain surgeons, of preventing wounds from scabbing. "This practice," he writes, "arises from the

conceit of surgeons who think themselves possessed of powers superior to Nature, and therefore have introduced the habit of making sores of all wounds." You will see that Hunter regarded the surgeon as standing in the same relationship to disease and injury as a gardener does to his plants. He may trim and prune, weed and delve, manure and support, and thus help them to thrive, but the power of growth does not lie in his hands; he can only assist that power. That lesson, I dare think, is needed at all times, and in none more than in the present. A soldier waiting wearily for movement to return to his stiffened joint or limp limb is apt to think that the means of recovery lie in the surgeon's hands, and expects a cure to be worked on him by active means. It is small wonder if in these circumstances the surgeon may be tempted to become more than Nature's mere assistant. In many modern operations the surgeon's share in effecting a cure is pre-eminent. A stone is removed from the bladder, an enlarged prostate from the pelvis, a calculus from the kidney, gall stones from the cystic duct, or a fulminating appendix from the abdomen, and thus the conditions necessary for a recovery are at once established. The surgeon's large share in such cures is beyond dispute. Nature cannot repossess the fractured ends of a broken bone, nor can she set the parts displaced in a fracture dislocation of the ankle or the dislocation of a joint. There, again, the surgeon's aid is an essential factor for a good recovery. But in the treatment of chronic ailments and disabilities which follow gunshot wounds it becomes a much more difficult matter to assess Nature's and the surgeon's share in the recovery. It is in these cases that we have to make certain that the means of treatment which we apply are founded on a rational and well-established basis.

To understand how Hunter's attitude towards the cure of disease became his second nature you must make his acquaintance during those twelve years he worked in his brother's dissecting room in Covent Garden—from 1748 until 1761, when he set out at the age of 33 to serve as a staff surgeon in the expedition to Belleisle, off the mouth of the Loire. It was his fortune during those twelve years in London to be associated with men who studied the human body to learn its living mechanism. He was still more fortunate in studying with men who preferred to dissect their knowledge directly from the actual part than to obtain it at second hand from the printed page. He learnt then to work, to love work, to become work's most willing slave. During those twelve years there were intervals of clinical work at Chelsea and St. Bartholomew's; he had been surgeon, pupil and house-surgeon at St. George's Hospital. But the knowledge which was to give him a foremost place amongst surgeons was gathered within the walls of the dissecting room. Just glance at the researches he carried out then: He worked at the descent of the testicle, and recognized that certain mysterious forces were involved in that operation of Nature. He saw that the condition of the testicle somehow controlled the act; he saw with curious eye what was merely an everyday observation to others—that the roots of shedding teeth were absorbed; that the extraction of a tooth was followed by the removal of its alveolus, and that such changes could not be effected unless the animal body was provided with a mechanism—a marvellous mechanism—for the removal of useless as well as dead parts. If only he could discover how Nature effected such changes, and could copy her methods, then why should he not use such methods to clear away those innocent and malignant growths which so often threatened life itself? The thread of that inquiry runs all through his laborious career: the removal of sequestra, the burrowing of abscesses towards the surface of the body, and the removal of sloughs. He never did discover that opsonic power—that "consciousness of imperfection" which makes useless parts fall a prey to surrounding healthy parts. It was during those twelve years he unravelled the structure of the placenta. He discovered then that nerves must be of different kinds and serve different functions, otherwise there could be no explanation of branches of the first and fifth cranial nerves terminating on the same area of nasal mucous membrane. He examined the earliest stages in the incubation of the chick, noting the origin of the red blood islands, their fusion and invasion of the embryo. It was then he commenced to probe the secrets of life itself, testing the peculiar properties of living matter by the manner it

reacted to cold of varying degrees. He proved that an egg was really a living thing; living matter did not putrefy; life keeps tissues sweet. He had inserted dead matter into abscess cavities to test the alleged digestive action of pus. Above all he had made an acquaintance with the hydra, and realized that even in its simplest form living matter had the power to move, digest, and feel and effect repair.

With a knowledge of those years you will be in a position to understand his attitude towards a party of wounded soldiers he met with on his arrival at Belleisle. Four wounded soldiers came in after being in hiding for a space of four days; one had received two bullets through his thigh, one was shot in the chest, a third was shot through the knee-joint by a bullet which pierced the lower end of the femur, while another was shot through the shoulder, involving the joint. "When they were brought to the hospital their wounds were dressed superficially and they all got well." That is Hunter's account of their surgical treatment. There was also another case, that of a grenadier of the 30th regiment who had been shot in the arm; the bullet passing between the biceps and the humerus. He had been taken prisoner by the French. The arm was fomented and a superficial dressing applied by the French surgeon. About a fortnight afterwards the grenadier escaped and came in with the wounds healed. "There only remained a stiffness in the joint of the elbow, which went off by moving it." Hunter cites those cases to support his contention that in many instances nothing is to be gained by opening and enlarging gunshot wounds. I do not cite Hunter's cases to suggest that the treatment which answered at Belleisle in 1762 is applicable to Flanders in 1917. I cite them because they illustrate Hunter's conviction that Nature is the master surgeon. We also note that he cured stiff joints by movement, and that he preferred voluntary to passive movement.

UNUNITED FRACTURES AND FALSE JOINTS.

I propose now to pass on to 1791, the last year but one of Hunter's life, to see him apply his ripest experience to the treatment of orthopaedic cases. In March of that year there came into his wards at St. George's Hospital a man suffering from simple fracture of the right femur, situated three inches below the great trochanter. Splints were applied and the man was rested in bed, but three months later it was found that no union had taken place. On inquiring into the matter Hunter then discovered that his patient had an ununited fracture of the right humerus of old standing. "It being evident from the circumstance of the arm that there was a natural backwardness in the constitution to form bony union," Hunter directed the man "to walk upon crutches and to press as much on the broken thigh as the state of the parts would admit, with a view to rouse the parts to action, forcing them by a species of necessity to strengthen the limb." To the initiated, Hunter's language and reasoning seem obscure, but to those who know the meaning he attached to "action" and to "necessity," the principles on which he based his treatment are plain. He recognized that the power of repair was inherent in living tissue; it was an essential property of living matter; it was roused into being by injury—his "stimulus of necessity." If he had coined a learned name from Greek or Latin, as has been done in the cases of other obscure properties of living matter—such as "chemiotaxis," "heliotropism"—he would have impressed his followers, but in reality made them no wiser. He set the man on crutches to call forth anew, by means of injury, the reaction of repair in the tissues between the fractured ends of the bones; the treatment was successful. "In the course of a fortnight there was an evident firmness in the bone, and in less than two months the patient could walk with the assistance of a stick."

I am able to show you the ununited fracture of the humerus of the case which was under Hunter's care in St. George's Hospital in 1791. Hunter was interested in the man, and allowed him to remain in hospital to pick up strength. During that period "he was seized with a complaint of his bowels—which carried him off." The femur was found to be firmly united by bony union, but the humerus "admitted of motion in every direction at the fractured part. . . . The arm was carefully dissected to examine

the state of the fractured parts, between which there was no callus, but a large bag filled with a glairy fluid, resembling synovia." A false joint had been formed, and inside that joint lay thirty to forty loose bodies similar to those which occur in joints. Their presence at once diverted Hunter's mind from the "failure of union" to a subject which had often occupied his attention in former times—the origin of loose cartilaginous bodies in joints. You cannot read and understand Hunter's works unless you know that in his opinion the film of "coagulable lymph" which united the opposite sides of an incised wound was a living bond. That film or plug of coagulable lymph (fibrin) was, he believed, endowed with a most marvellous property. If it lay between the ends of a broken bone, it then took on "from a species of sympathy" the texture and qualities of bone; if between the cut ends of a tendon, then it assumed a tendinous texture; if against the cut end of a nerve or a vessel, then it became nervous or vascular in texture as the case might be. If, then, blood were effused into a joint and coagulated on the surface of the articular cartilage, what was more natural than to suppose that it would, as it became organized, assume the nature of cartilage and form the bases of the loose bodies which occur within, and disturb the action of joints; the occurrence of loose bodies within the false joint of the humerus he regarded as a vindication of his theory. Hunter's theory accounted for many appearances, but fifty years later the microscope showed that naked-eye appearances are sometimes deceptive. But no future discovery can ever destroy the utility of a working hypothesis.

MUSCLES.

We see Hunter at his very best when he comes to speak of cases in which damaged muscles are involved. From his first day in the dissecting room to the fatal visit to St. George's Hospital in 1793, those mysterious and marvellous power-machines of the animal body held as in a vice his curiosity and his ingenuity. If it is true, and I think it is true, that a knowledge of muscles is the beginning and the end of all orthopaedic treatment, then Hunter merits our attention more than any surgeon. Let us see him brought face to face with a case where muscles are involved. He had called on a lady who suffered from the after-effects of a broken patella. She was totally unable to use the limb and was wheeled about in a chair. "Having spent a whole night in considering the probable cause of her loss of power, it appeared to me that the space between the two attachments of the rectus (between the origin and insertion of the muscle) being much shortened, the utmost degree of its contraction would scarcely be able to straighten itself, much less move the patella and leg also. . . . I advised her to sit as before (with her leg dangling free of the floor), but, instead of having the leg moved (passive movement) to exercise the quadriceps), to move it herself. This she could not in the least effect at first. I considered, however, . . . if the influence of the mind were freely exerted on the muscle, it would gain this power of contraction." So it proved; the lady gradually obtained the control and use of her limbs.

In this case Hunter's treatment was based on his knowledge of muscular action. He had noticed that a muscle works within definite limits. It can contract under the domination of the will until the shortest limit allowed by the flexion of the joint is reached; it can elongate to the furthest limit permitted by the extension of the joint. Hunter observed, however, that under certain circumstances—if a tendon be cut or a bone broken—the muscle could and did contract beyond the shortest limit of voluntary contraction. A muscle has a power of contraction beyond that which can be given by the will. In the case of the broken patella he conceived that the extensor quadriceps was in the stage of extreme contraction, and therefore lay outside the influence of the will, but he knew that the will could by effort dominate a muscle in all positions; he knew that a voluntary muscle was the most educable of all structures. It was on these principles he based his treatment. How many muscles are there to day which need the simple reasoning of Hunter's mind to help them! By exercising his will a patient may do more to help the recovery of a muscular function than can be accomplished by the most complicated of gymnastic machines.

TENDONS.

When Hunter was appointed surgeon to St. George's Hospital in 1768, and thus obtained the first real opportunity of applying his peculiar store of biological knowledge, he was already 40 years of age. In the previous year there happened two notable events in his life: he was elected to the Royal Society and had his tendo Achillis ruptured. It is the latter event which interests us here. He had been suffering from cramp in the calf of his leg (he was subject to muscular spasms and cramp), and he had been dancing; he was not married then. He noted that the rupture was unattended by pain; it was only when repair set in that the tendon became sensitive. He noted further that he had lost all voluntary control of muscles yoked to the tendon, by no effort of will could he make the muscles of his calf contract. But he also recognized that in sleep the muscle obtained a power of involuntary contraction. He clearly did not understand why the muscles should pass out of action during consciousness, and assume a power to act during sleep. He knew nothing of the structure and functions of the spinal cord, nor the significance of that kind of action we call reflex—that knowledge came with Marshall Hall. He based his treatment on those two simple observations. He encircled the calf of the leg with a bandage to prevent "involuntary movements," and applied an apparatus during the night "to steady the muscles." After the first day or two following the accident the patient was allowed to walk about, with the heel of the boot somewhat raised on the injured side, and was instructed to step off the inner side of the heel, as is the manner with those who suffer from flat-foot.

At the time Hunter suffered from this accident he had already acquired two acres of land at Earl's Court, where he established what would be described nowadays as an experimental station. Healing of tendons became a matter of interest to him. Ottley states that he cut the tendons of dogs by a subcutaneous method—the earliest record we have of such operations. We know from Everard Home that one of the deer then kept at Earl's Court had a tendo Achillis cut for a double purpose—to keep it from jumping the enclosing fence at Earl's Court, and at the same time to provide information as to the mode of healing. I can show you fine specimens of tendon repair which Hunter obtained by experimental means. He found that a gap between the separated ends was no bar to union; coagulated lymph could eventually provide a strong bridge across a wide gap. After his own death it was found that the cicatricial bond in his tendo Achillis had become calcified.

THE MINIMAL MUSCLE LOAD AND THE WILL.

We come now to another side of Hunter's teaching regarding the nature and action of muscles, which has an important application to present-day conditions. We may call this part of his teaching, in order to distinguish it, the principle of the "minimal load." Let me explain by use of an example what is meant by that expression. Let us take the case of a labourer who has just recovered from typhoid fever. We want to test his strength. We ask him to lift and carry a sack containing 2 cwt. of coal. We should be very foolish if, when we find he cannot move it, we concluded that he has no strength. Yet that is how the strength of weakened and disabled muscles are being tested now in many instances. Let us take the case of the deltoid muscle. If we start it into action as the arm hangs by the side it has to move its maximum load at the very start; it has then to lift the weight of the arm when its purchase is at a minimum. The deltoid may, when so tested, appear absolutely paralysed, yet if the disabled man lies on his back with his arm half abducted and its weight supported on a board, and we then apply the principle of the "minimal load," it may be found that the muscle, far from being paralysed, has a very considerable power of action.

It is characteristic of Hunter that he never did halt or bend to point out the immediate practical application of his observations and "principles." He gives us, as it were, the stick or the knife, but expects that we ourselves will do the whittling. That is why Hunter is a prince to the thinking surgeon and only a babbler to the merely practical one. He tells you the position of a joint which gives

a muscle its greatest power: he points out that the weight of a limb is a heavy burden; he recognizes that muscles may be weakened from many causes; he insists on the mastery which the will can obtain over them, but nowhere does he formulate these observations into a system to be applied to the treatment of disabled muscles. Indeed, I must own that without the aid of my friend Dr. W. Colin Mackenzie I should never have realized the practical bearing of many of Hunter's facts. Dr. Mackenzie makes no claim to be the discoverer of the "minimal load" treatment of disabled muscles, but I am certain that no one has realized its practical importance more than he, and no one has realized and applied the right methods to the restoration of disabled muscles with an equal skill. When you have discovered that a muscle loaded to a minimal degree can exhibit a spark of movement, then you have to bring the will to bear upon that spark. As it increases you will be able gradually to increase the load and thus nurse what is often regarded as a useless structure back to a fair or full degree of vigour. Dr. Mackenzie's methods, as revealed by his published results, bespeak infinite patience on the part of both surgeon and patient, and these are qualities which are hard to obtain in either surgeon or patient. In this we here come back to the bed-rock of Hunterian teaching: the only certain means of treatment are those which employ the natural recuperative powers of the body.

One other aspect of Hunter's teaching has a bearing on the treatment of muscular defects. He was not the first to realize that it is impossible for a muscle or a set of muscles to contract without their antagonists being called into action at the same time. He learnt that doctrine as a student from Winslow's still excellent textbook of anatomy; but he did realize more than any one who went before him that the relaxation of the extensor or antagonist muscle was just as important, as real, and as vital an act as the contraction of the flexor or prime-moving muscle. He never could determine whether the relaxation of the antagonist was due to a voluntary or an involuntary stimulus. That doubt, we shall see, has been resolved in recent times. The surgeon must always think in terms not of single, but of antagonist muscle groups.

Remarks

ON

THE TREATMENT OF NEURASTHENIA
AND PSYCHASTHENIA FOLLOWING
SHELL SHOCK.

By R. T. WILLIAMSON, M.D. LOND., F.R.C.P.,
CONSULTING PHYSICIAN, MANCHESTER ROYAL INFIRMARY.

A VERY large number of cases of persistent neurasthenia, psychasthenia, and allied conditions, following shell shock are now under treatment in England. Similar affections are also caused by the shock or continued anxiety of Zeppelin raids and the continued anxiety from other risks of injury. The symptoms may commence suddenly after one severe shock, or gradually after repeated shocks. In many of the severer cases the patient is unable to carry out his duties, military or civil, for a long period, and we have the expense of his continued pension. It is important both for the patient and the country that he should recover as early as possible. The treatment is, however, often very unsatisfactory, and to many medical men very uninteresting. It should be psychological as well as medical. Very slight cases may improve rapidly after a short rest, but in many of the severer cases the symptoms are very persistent. The patients are sent into hospital; they often rest most of the day, take little exercise, and are not occupied definitely in any way. They have time for thinking and brooding all day over their experiences and symptoms, and for thinking of the time when they will be expected to return to the front, or will be exposed to the same risks. Very many of the severer cases do not improve much, and after weeks or months leave the hospital with the symptoms well marked.

The following is a line of treatment which, from a study of these severer cases, I consider useful and would

emphasize, and I think these suggestions will be found useful also by others.

Importance of Diagnosis.

The patient should be examined carefully, the symptoms noted, and signs of organic disease searched for. It is very important to exclude early general paralysis of the insane, organic diseases of the nervous system, commencing insanity, and organic diseases of the various systems. When this has been done, malingering or "shirking" should be carefully considered and excluded before the treatment is commenced. Excluding cases of functional paralysis, loss of speech and deafness following shell shock, etc., which are not considered in this article, and considering only neurasthenic and psychasthenic symptoms following shell shock, the differential diagnosis from malingering or "shirking" is sometimes very difficult. Though very many cases of malingering and shirking are seen, in a large number of cases the symptoms are undoubtedly pathological, and the medical man who regards the cases as all "shirkers" is unsuitable for treating such patients, and should leave the treatment to someone who understands their condition better. Some of the men who have distinguished themselves by the greatest bravery and daring in this war, and received the V.C., D.C.M., and other medals, and some of the men who have been able for months to view the shell fire with the greatest possible calmness, have suffered eventually from shell shock. Such cases should be carefully considered and examined before being diagnosed as malingerers or shirkers. The symptoms may continue long after the patient is discharged from the army and when he has no fear of further risk, though it is important that he should be relieved from anxiety on this account. Further, after suffering from neurasthenia, the patient may recover and return to the front and behave with the greatest bravery.

In this article the symptoms of the neurasthenia and psychasthenia resulting from shell shock will not be described, but the following may be mentioned as they are often especially well marked: mental irritability, sensation of fatigue, headache, difficulty in fixing the attention on any subject, obsessions and sleeplessness; the patient is very nervous and is easily and greatly startled by slight noises; often he is constantly thinking of his past experience of the shell fire, and he has great difficulty in fixing his attention on any other subjects. He often sleeps very badly, it may be only one or two hours at night, and when awake at night is constantly thinking of the war. It is interesting to note that many symptoms are often observed which are frequent in Graves's disease. A fine tremor of the hands like that of Graves's disease is very common, also sweating and palpitation are common, and a von Graefe's symptom in slight degree often noted—less marked but similar to that of Graves's disease. Exophthalmos and thyroid enlargement are not observed.

Anxiety with Respect to Further Shell Shock.

When the diagnosis is quite clear and malingering and organic diseases can be excluded, and the symptoms well marked and persistent, it is desirable, in the first place, that the patient should have no further anxiety from shell explosion and similar risks. He should be sent to a hospital or home in England, or far from the front, and treatment carried out. If the symptoms are very severe or have been very persistent, it is desirable that the patient should be informed that he will be transferred to some department of the army at home, permanently or temporarily, where no further risk from shell shock will occur, or to munition work or to other occupation. This is a point of much importance. If the patient is placed in a hospital and allowed time to think and brood over his experiences he often becomes very anxious and dreads the time when he will be sufficiently well to be sent back to the front and exposed to further risks. This great anxiety and dread of a repetition of the shock from shell explosion or similar risks is a great hindrance to recovery and the patient should be freed from it as early as possible. But this anxiety is only one cause of the persistency of the symptoms, and when the patient is relieved from all anxiety of further risk the symptoms often continue, especially if he sleeps badly. Also anxiety respecting his family or those depending upon him may hinder recovery; he should be relieved from this if possible.

Treatment.

He should be told that he is not suffering from any disease which is dangerous to life, that he will undoubtedly recover, and that perseverance in the line of treatment advised is most important. He should be kept as cheerful as possible. As will be mentioned subsequently, all war news should be cut off at once and conversation about the war should be avoided.

At first a short period of complete rest is desirable, and this is well combined with the "sleep treatment" described in the next section. He should be well fed and any gastric or intestinal troubles treated. The bowels should be kept regular, and any affection of the abdominal or thoracic organs or any other ailments (malaria or dysentery) or their results should be carefully treated. In suitable weather the bed or sofa should be drawn into the open air and sunshine when a garden is attached to the hospital or house where he is treated.

Sleep Treatment.

In a large number of the cases the patient sleeps very badly indeed, for weeks or months, and may be able to sleep only for two or three hours or less every night. Often when awake at night he is thinking of his experiences at the front. It is most important to try and check the insomnia as promptly as possible. Trional is one of the most useful drugs I have tried; in a few cases 30 grains of potassium bromide at night may be of service. A mixture of potassium bromide, with small doses of chloral hydrate, and tincture of opium, or syrup of codeia is sometimes very useful. Other drugs will also be of service. If adalin or chloralamide can be obtained they are very suitable.

When the patient is able to sleep better he often improves rapidly, but in some cases after he is able to sleep well the symptoms continue, especially if he is fearing a return to the front or if he is constantly thinking over his experiences. On the other hand, as already mentioned, if the patient sleeps unsatisfactorily the symptoms often continue even when all dread of further war risk ceases. During the day very often the patient is constantly thinking about his experience of the shell explosions, and the war, or of his symptoms, except when he is occupied by reading, conversation, or in some other way. A very important point is to check thinking on these subjects.

For this a sleep treatment for a few days is often useful. The patient is kept asleep part of the day as well as the night by drugs; potassium bromide may be given three times during the day in addition to the trional or bromide at night, or trional is given at night, and after dinner at midday. Or a mixture containing potassium bromide, with small doses of chloral hydrate, and tincture of opium may be given two or three times during the day (in place of the bromide or the trional). But the dose of the drugs should be carefully regulated, and only just sufficient should be given to keep the patient asleep part of the day. The drugs should be continued for a few days only, and discontinued at once if bad symptoms are noted. He should be closely occupied when awake by something interesting to him—games, draughts, dominoes, patience, billiards, handwork, netting, zigzag puzzles, reading, etc. In summer, when the weather is suitable, the bed may be drawn into the open air if a garden is adjacent to the hospital or bedroom. This sleep treatment may be carried out for four or six days, but it should be very carefully observed.

If the patient can sleep well during the night and half of the day he often improves decidedly. After a dose of 15 grains of trional at night one of my patients would constantly sleep all night and all morning until midday or 1 p.m. But often another dose of trional after midday dinner is useful. Some require very large doses of drugs before they sleep; in these cases we may be content with sleep during the night alone, and the drugs should not be pushed and should be discontinued during the daytime.

This sleep treatment is often of very great service for a week at first, but for some time trional or other drug may be required at night.

Mental Treatment: Occupation.

After the sleep treatment it is desirable that the patient should try to cease thinking about the war and his past experience and of his symptoms.

(a) He should avoid reading war news in the papers, journals, and books. In conversation the war should be avoided. Cutting off all war news in this way is of distinct service. Also he should not discuss his symptoms with others and the symptoms of other patients should not be related to him.

(b) He should direct his thoughts to a new subject, or to a subject not associated with war, and best of all to some new occupation.

(c) The occupation should be one requiring some thought, and he should apply himself very closely to this occupation.

(d) The occupation should be one which is very interesting to him, and which is likely to become more interesting as it is continued.

(e) If the occupation is one which can, after a time, be carried out mechanically without thinking, then the patient is liable to wander back to his old thoughts about the war, whilst he is doing work. It is then often useful to vary the occupation, so that closer application will be needed. Thus, if after spending much time in netting, he finds that he no longer requires to think about the work, he may change to fretwork, or some other work, so that closer application will be necessary.

Suitable Occupations.

The occupation most suitable will vary with different cases. The following may be mentioned:

Games, such as draughts, dominoes, cards (especially patience, which the patient can play alone), billiards, zigsaw puzzles, etc.

Hand occupations, netting, fretwork, wood-carving, "poker work," sewing, knitting and needlework, rush work, raffia work, basket work. Netting mats is often very suitable. Handwork in the ward, bandage rolling, knife cleaning, etc., may be useful.

The study of French or foreign languages in some cases may be tried if he is interested in the language, and finds that he is not wearied by it. Drawing, painting, pen painting, photography, music, typewriting, may be of service.

Later, when he is stronger, gardening and outdoor games, field work, grass cutting, motor wagon driving, etc., are suitable. Driving a motor wagon or transport is very suitable if the patient is interested in it, and some patients will find it of much service. The driving of a motor wagon requires close application; it may be interesting to the man, and the calls for attention are so varied that his thoughts are fixed more or less on the work in hand. He is also out in the open air, and great physical fatigue is avoided.

The occupations must be interesting to the patient, and his attention must be kept to them very closely; hence the most suitable kind of occupation will vary much in different cases; one patient will be interested in netting mats, the next will find it irksome. He should therefore be allowed to take up one or two of the most interesting. He should sell his work if possible, so that he may have the pleasure of earning money; if wealthy, the money may be given to some charitable institution.

Games are useful at first, but very soon most of the time should be devoted to occupations. Later work in the Army Service or Motor Transport Corps or munition work may be suitable. The patient may improve rapidly if he is transferred to some occupation in England in which he becomes deeply interested and has no further risk of shell shock—such as the training of cadets, training in the machine gun section, etc.

SUMMARY.

To recapitulate, the important points which I desire to emphasize in the treatment suggested in this article are:

1. All *anxiety* and fear of further exposure to similar risks to life, and anxiety from other causes, should be removed if possible, and the patient should be definitely told that he will certainly recover.

2. The *sleep treatment* is very useful. At first hypnotic drugs may be given both at night and during the day for a short time; so that the patient may sleep all night and, for a few days, also during part of the daytime.

3. He should *cease thinking* of the war and his experiences. This may be brought about (a) at first by the sleep during part of the daytime as well as during the night as just described, and by occupation whenever he is awake; (b) afterwards he should be kept asleep all night (by drugs); but during the day the drugs should be discontinued and he should be kept fully occupied in a suitable way.

4. As regards the kind of occupation:

(a) A new subject or one not associated with his war experience is desirable.

(b) Very close application to the work in hand is important.

(c) The occupation should be one requiring thought, and if the patient finds, after continuing it for some time, that it can be done mechanically, the occupation should be changed or altered so that thought is required.

(d) It should be one very interesting to the patient, and one which will become more interesting.

Many other methods of treatment have been tried and recommended, but I have not attempted any review of the literature of the subject, and have only considered the treatment which, from my own observations, has appeared suitable. In many of the severe cases recovery is very slow, but I think the line of treatment suggested will be found of much service.

THE RED BLOOD CELL COUNT AND HAEMOGLOBIN CONTENT OF THE BLOOD IN DISORDERED ACTION OF THE HEART.

BY

A. GOODMAN LEVY, M.D., M.R.C.P.,

LATE CAPTAIN R.A.M.C.(T.F.); PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

(Under the direction of the Medical Research Committee.)

THE accompanying table of estimations sets out the results of the examination of fifteen patients at Hampstead Military Hospital. These were unselected cases of D.A.H. (disordered action of the heart) of all degrees of severity; that is to say, they exhibited the group of symptoms associated with this nomenclature, in varying degree. None of the patients had been "gassed," and none exhibited unusual symptoms, such as nocturnal dyspnoea.

The haemoglobin was estimated by Haldane's haemoglobinometer. The percentage was taken as the mean of two observations, one at a dilution which caused the tints to match, and the other at a further dilution which caused the specimen to be slightly paler than the standard tint. This tends rather to overestimate than to underestimate the percentage. The red cell count was made in a Zeiss-Thoma counting chamber, which was estimated by micrometer measurement to err (if at all) on the shallow side; it would not, therefore, tend to yield excessive estimations.

Two specimens of blood were taken from a puncture in the ear of a patient in separate pipettes at the same sitting; 160 squares of the counting chamber were counted from each specimen, and the average of these two estimations was taken as the true blood count.

The observations were made between the hours of 10 and 12 in the morning on the patients who had taken no exercise and who had remained indoors. This series of observations was made in March and early April during an exceptionally cold and severe spell of weather.

The average number of red cells is commonly given as about 5,000,000 per c.c.m. in males, but there does not appear to be any complete agreement on this point. A rise normally takes place after exercise and at certain stages of digestion. The count also varies with age, and, according to von Limbeck,¹ this variation is considerable; thus he gives the average count between 19½ and 22 years as 5,600,000, 25 to 30 years as 5,340,000. A very high average count was found by P. W. Hawk¹ in a number of healthy young athletes in training—that is, 5,600,000 immediately before exercise.

Case.	Age.	Red Cells.	Hæmo- globin.	Colour Index.	Remarks.
			Per cent.		
1	31	6,600,000	97.5	0.74	Severe D.A.H.
2	26	6,465,000	99	0.76	Severe D.A.H.
3	26	6,275,000	99	0.79	Mild D.A.H.
4	24	6,135,000	93	0.76	Moderate D.A.H.
5	24	6,055,000	100	0.82	Severe D.A.H.
6	—	5,960,000	89.5	0.75	Chronic mild D.A.H.
7	27	5,915,000	91	0.76	Chronic severe D.A.H.
8	19	5,900,000	97	0.82	Severe D.A.H.
9	18	5,867,000	90	0.76	Chronic moderate D.A.H.
10	32	5,675,000	91	0.84	Severe D.A.H.
11	31	5,652,000	—	—	Moderate D.A.H.
12	25	5,526,000	92.5	0.83	Mild D.A.H.
13	27	5,495,000	89.5	0.81	Mild D.A.H.
14	34	5,110,000	92	0.9	Chronic mild D.A.H.
15	32	4,892,000	87	0.89	Severe D.A.H.

The average of the fifteen patients suffering from D.A.H. was 5,837,000, which is quite in excess of anything previously observed in healthy individuals, and is the more remarkable in view of the fact that these men were invalids, who had for the greater part spent a considerable time in hospital before the estimation was made. The average age of these patients was 28 years. One-third of these patients had a count of over 6,000,000, and more than one half (53 per cent.) had a count of 5,900,000 or over.

The hæmoglobin content was for the most part below the normal 100 per cent., the average being 93.4 per cent. (ranging from 87 per cent. to 100 per cent.). Relatively to the number of red cells the hæmoglobin content was low, the average colour index being 0.8.

The cases have been roughly described in the table according as they are severe or mild, chronic, or otherwise, and it is evident that no relationship can be established between these particulars and the red cell count. It is apparent that a high blood count may be found in a patient, such as Case 6, able to undertake a half-hour's physical drill and march three miles without pronounced discomfort, and that a low count may occur in a patient, such as Case 15, readily distressed and only able to undergo mild resistance exercises.

The leucocytes were not counted in this series of cases. The existence of a leucocytosis in cases of D.A.H. has been established and described by Mrs. Briscoe.¹

Multiple observations made at intervals on other individuals indicate a degree of variability in the count, but this is a matter that requires further investigation: amplification of these observations is evidently desirable in other respects, but, my work having been interrupted, I publish these records as they stand.

It does not appear possible in the present state of our knowledge of the pathology of D.A.H. to suggest the significance of this polerythrocythaemic condition.

THE first meeting of the Spanish National Medical Congress will be held at Madrid in April, 1918 (21st to 26th). The work will be divided among seventeen sections. The president is Professor Ramón y Cajal, well known as the author of works of the highest importance on the structure of the brain and spinal cord. In the summer of the present year he published an autobiography under the title of *Recuerdos de mi Vida* (Recollections of My Life). Santiago Ramón y Cajal was born in 1852, and studied at Saragossa, where his father was professor of anatomy. After graduating in 1873, he served as an army medical officer in Cuba. In 1881 he was appointed Professor of Anatomy at Valencia; in 1886 he became Professor of Histology at Barcelona; and in 1892 he was called to the corresponding chair at Madrid.

ACUTE TUBERCULOUS BRONCHOPNEUMONIA
WITH PNEUMOTHORAX,SECONDARY TO TUBERCULOSIS OF THE PERI-
BRONCHIAL LYMPH NODES.

By ARCHIBALD MALLOCH, B.A., M.D.,

CAPTAIN CANADIAN ARMY MEDICAL CORPS.

The following case is reported because it illustrates the relation of certain more chronic tuberculous lesions to acute tuberculous pneumonia, and the relation of the latter to pneumothorax.

Pte. J. G., aged 18, was admitted at midnight on January 26th, 1917, with a diagnosis on his field medical card of "incipient trench feet."

Previous History.—He had been a farm worker. During his last few days at the front he had had a cough and pain in the right chest; in the ambulance train this pain was quite sharp.

Clinical Aspect.—The feet were slightly swollen and tender but nowhere was the skin broken. The temperature was normal on admission, and the pulse was 92; the respirations were not rapid, and he made no complaints referable to his chest. He was able to sit up in bed and wash himself, appeared perfectly comfortable, and soon dropped off to sleep. At 4 a.m. (January 27th) he awoke suddenly with very severe pain in the right side of the chest and upper abdomen. He was extremely dyspnoeic and cyanosed. The respirations were 40, the movements of the chest were very shallow, the pulse 152, and the temperature 102.6°; it was 105° a few hours later.

He was almost immediately transferred to the "pneumonia hut," where there is an abundance of fresh air. The apex beat of the heart could be seen in the fifth interspace 14.5 cm. to the left of the middle line, and on percussion the right border was found 2.5 cm. to the left of the left border of the sternum. The heart sounds were clear and no murmurs were heard. The right side of the chest did not move. Tactile fremitus was much decreased over the right lower axilla and base, and at the base behind there was an area of flatness extending upwards for about five inches. Above this in front the percussion note was hyper-resonant. Over the areas of the middle and lower lobes the breath sounds were amphoric, and accompanied by tinkling sounds; over the upper lobe in front the respiratory murmur could scarcely be made out. The amphoric breathing was transmitted to the left of the sternum, and was marked at the level of the second costal cartilage. On the right side, behind, the breath sounds were poorly heard. The *bruit d'airain* was heard over the right chest, and the succussion splash was readily made out. On the left side there was no dullness, but the respiratory murmur was harsh, although nowhere "blowing."

A diagnosis of right-sided pneumothorax was now made, and this was thought to have been caused by the rupture of a tuberculous cavity in the lung. Pneumonia also was thought to be present. A very grave view of the case was taken, but the patient held out until February 2nd. The course of the disease was not without interest.

January 27th: A small amount of fluid was withdrawn from the right base. January 28th: The temperature was 104°, respirations 32, pulse 118. Blood was seen in the sputum. January 29th: Temperature 99.5°, respirations 32, pulse 120. The amphoric breathing was not heard so high up on the right side of the chest, but above this there were numerous rhonchi. No change in the position of the heart was made out, so the pneumothorax was thought not to be "valvular" in nature. January 30th: Temperature 99°, respirations 30, pulse 124. The patient became slightly delirious and was much cyanosed. The upper level of flatness in the right thorax had apparently not changed. The amphoric breathing was still distant and heard on the right side only over a small area close to the lower end of the sternum. Over the right upper lobe the respiratory murmur was inaudible. February 1st: Temperature 97°, respirations 36, pulse 100. There was no blood in the sputum. The patient was not so cyanosed and his pulse was stronger. The apex beat was seen at a point 10.5 cm. from the middle line—that is, a little nearer its normal position. The amphoric breathing at the pulmonary cartilage was not so pronounced. Although there was still pain in the right chest, it was thought that the pneumothorax was decreasing. Over the left upper lobe the breath sounds were still harsh, and numerous moist râles were heard. February 2nd: The patient was again very cyanosed, with much wheezing, and was unconscious most of the time. No blood in the sputum. The apex beat was in the same position as on the previous day. The amphoric breathing was again heard higher up on the right side of the chest and at the base of the heart to the left of the sternum. Still no increase in the area of flatness was observed. Sharp moist râles were heard over the left upper lobe, with prolonged expiration. Numerous bubbling râles were heard in the left axilla. It was thought that the patient had tuberculosis of both lungs. Temperature subnormal, respirations 40 to 48, pulse 120. He died at midnight of cardiac failure.

I am indebted to Major Lawrence J. Rhea, C.A.M.C.,

for the following notes on the pathological aspect of the case:

Pathological Report.—Report on the fluid withdrawn from the right pleural cavity on January 27th: "There is about 10 c.cm. of turbid yellow fluid. The predominating cells are polymorphonuclear leucocytes, although there are a considerable number of endothelial cells and lymphocytes. Smears stained with carbol-fuchsin show numerous tubercle bacilli. These organisms are mostly extracellular in position, although some of them have been ingested by the endothelial leucocytes. There are also a few small diplococci organisms." Report upon the examination of the sputum of January 28th and 30th: "A number of selected particles from the sputum were stained for tubercle bacilli, and after careful and prolonged search only two were found."

Post-mortem Examination.—The skin and pectoral muscles were dissected in such a way as to make a water-tight pouch bounded by the ribs and the dissected tissues. This pouch was now filled with water and a puncture made beneath the water between the second and third ribs into the right side of the thorax. Air, under slight pressure, bubbled through the water. The right thoracic cavity contained a large amount of turbid fluid. The right lung was greatly compressed and forced upwards and inwards against the bodies of the dorsal vertebrae. Over the parietal pleura, especially at the angles of the ribs and over the upper surface of the diaphragm on the right side, there was a layer of plastic lymph several millimetres in thickness, which was easily removed. The visceral layer of the pleura also showed a lymph exudate which was thickest over the posterior surface of the upper lobe. The mediastinum and its contents were pushed to the left. The cause of the pneumothorax—that is, the communication between the respiratory passages and the pleural cavity—was not at first evident, but after removing the lymph exudate from the lower part of the posterior surface of the right upper lobe a small perforation about 2 mm. in diameter was found in the visceral layer of the pleura. The right upper lobe was crepitant in its upper but not in its lower half. A longitudinal section was made through the lower part of the upper lobe and showed the following: There is a band, about 5 cm. in width, of acute tuberculous bronchopneumonia extending from a point close to the hilum of the lung to the periphery of the lower part of the upper lobe. This band follows the general direction of one of the branches of the bronchial tree. For the most part the small greyish-white areas of tuberculous vary in size from about 0.5 mm. to 10 mm. in diameter. One small area of tuberculous, just beneath the visceral layer of the pleura, has broken down, and by involvement of the overlying pleura has caused the tiny perforation already described. This sharply limited area of involvement of the lung is explained as follows: The lymph nodes about the hilum of both lungs are enlarged, and are the seat of old non-active tuberculous. There is, however, one node on the right side which shows changes due to active disease. This node, which is firmly attached to one of the bronchi, has undergone acute necrosis and has led to the perforation of the bronchus. As a result, there is established an opening from the medulla of a tuberculous lymph node directly into a bronchus. The area of diseased lung corresponds to that supplied by the perforated bronchus. There is no gross evidence of old tuberculous in either lung. The left lung shows septic bronchopneumonia. The right side of the heart is dilated.

Comments.

1. This case demonstrates a well-known fact—namely, that the finding of pneumothorax clinically, and of numerous tubercle bacilli in the pleural effusion, does not compel us to diagnose extensive disease of the lung.
2. The amount of fluid in the pleural cavity was underestimated.
3. The changes in the position of the heart and the changes in the clinical signs, especially that of the amphoric breathing, may, we think, be explained. The return of the apex of the heart towards the middle line, and the decrease in the area of amphoric breathing, were evidently due to the fact that the air in the chest was being absorbed after the perforation of the lung had been closed by lymph. The fact that the amphoric breathing was again heard higher up on the chest, may possibly be explained by the greater compression exerted upon the residual air in the pleural cavity by the increasing amount of fluid.
4. The source of the infection of the lung was found.
5. The area of lung involved corresponded to the distribution of that bronchus which had been perforated by an ulcerating tuberculous lymph node.
6. The production of the pneumothorax was due to a factor which plays such an important rôle in many diseases, namely, the accident of position of one of the small foci of acute tuberculous bronchopneumonia.

To Dr. George E. De Schweinitz, now serving as a major in the United States Medical Reserve Corps, has been assigned the task of compiling a handbook on ophthalmology for the use of the Surgeon-General of the army.

NOTES ON TRENCH FOOT.

BY

CAPTAIN R. T. DOBSON, R.A.M.C.

UNDER the exigencies of modern campaigning winter warfare imposes on the troops holding the line conditions to which, previous to the winter of 1914, no armies had been subjected, and to counteract which no measures had been devised, with the consequence that in that winter an enormous proportion of the troops were incapacitated by the various lesions to which as a whole the term "trench foot" is applied.

As the conditions favouring the occurrence of these became better understood, and measures were devised to combat them, the losses from the occurrences of trench foot became less serious in each succeeding winter.

Whilst in charge of the arrangements for preventing and treating lesions of the feet and legs occurring in the troops occupying a certain area, all the cases of so-called trench foot passed through my hands and came under my care; this gave me exceptional opportunities of studying the various kinds of lesions included under the term.

There were three distinct types. The first, which comprised about 15 to 16 per cent. of the cases, commenced with symptoms of marked constriction of the blood vessels, causing the feet to become in the first stage numb, cold to the touch, and strikingly bloodless in appearance. The second type, comprising 4 to 5 per cent. of the cases, commenced as ordinary chilblains. The third type, which comprised the remainder of the cases, arose as septicly infected lesions of the skin, and were obviously due to neglect of ordinary cleanliness or ill-fitting foot-gear, or both. The first two types are to a certain extent unpreventable, but the third should be quite avoidable with ordinary care.

The period during which the observations were made extended from the beginning of November, 1916, to the latter part of February, 1917. The first two-thirds of this period was very wet with low temperature, whilst the latter part was dry and frosty with a temperature much lower than normal, a hard frost prevailing most of the time.

During the rainy period the trenches and ground were very wet, necessitating the almost continuous wearing of thigh gum boots. In the dry frosty weather the men were able to revert to the use of their leather ankle boots and putties.

The greatest influx of cases occurred towards the end of the wet period, although some of the more severe cases occurred during the dry frosty weather.

The cases of the first type mentioned below, those occurring during the wet period, resembled closely the milder cases of frostbite, under which term the cases occurring during the dry frosty weather should properly be included.

Four per cent. of the cases gave a history of having suffered from a mild form of Raynaud's disease; 50 per cent. gave a history of having been troubled by persistent cold extremities, blueness of the hands or other signs of poor capillary circulation. About 30 per cent. of these were also subject to chilblains, whilst about 10 per cent. gave a history of having suffered from chilblains only.

The wearing of gum boots did not appear to prevent entirely the onset of the complaint, since 80 per cent. of the total cases included under the term trench foot and occurring during the wet period were wearing them. In fact, where they were worn continuously during the tour in the trenches, as was the practice with most of the men, they soon became wet inside from condensed perspiration, and the clothing covered by them became soaked by perspiration also, thus subjecting the legs and feet to the very conditions the boots were devised to avoid. These conditions were aggravated by any active work which caused them to perspire undertaken by the men whilst wearing gum boots. On the other hand, the lack of exercise to which the exigencies of trench warfare subjects the men whilst in the front line also has a harmful effect on the circulation, in the lower limbs especially.

The age of the men did not appear to have much influence on the onset or course of the complaint, but the length and thoroughness of their physical training did, as it more easily affected those who had come from sedentary

occupations and had only been in the army a comparatively short time.

Fifty per cent. of those cases which began with constriction of the blood vessels began first to show signs on the fourth day in the trenches, and 46 per cent. on the third day. The remainder had been working in wet trenches, gun pits, or wagon lines behind the lines, and wearing gum boots more or less continuously.

The following is the history of a typical case commencing with constriction of the blood vessels:

Pte. E. P., aged 26. In front line trenches eleven days. He wore long gum boots continuously during his stay in the trenches, as he had to wade knee deep through water to get to a bombing post, where he stayed two days. He then returned to the trench for two days and then had another day in the bombing post. During his stay in the bombing post he was ankle deep in water the whole time, and his clothing was soaked with rain during most of his stay in the trenches.

He had a change of socks the day after getting into the trenches, but they got damp after being worn a few hours in spite of the fact that he was wearing gum boots. He rubbed his feet for fifteen minutes each morning with whale oil. His feet began to give trouble after he had been in the front line two days, that is, on the third day. They first became numb and very white in appearance. This condition lasted about thirty-six hours. They then became very painful, red, and swollen, and the skin became very shiny.

This stage lasted about three days, after which the swelling began to subside. A day or two later the skin began to come away between the toes, leaving a raw surface, which healed rather slowly. The skin on the soles of the feet became wrinkled and loose, and finally peeled off, leaving the soles of the feet tender for some time afterwards.

A slight rise in temperature and some transient albuminuria was noted in the more severe cases. Cases of this class very closely resemble the milder cases of frostbite, and in their second stage are hardly distinguishable from the more severe cases of chilblains; however, there is no history of the feet having passed through the stage characterized by marked loss of sensation and vaso-constriction, and the affection is more likely to be confined to one foot. Blistering and excoriation of the skin are much less common and marked in the case of chilblains.

In some of the cases commencing with vaso-constriction, pain, which is worse at night and neuralgic in type, is marked and severe from the commencement of the complaint, lasting for some time after all signs of inflammation have disappeared and the patient is able to walk.

In a few cases the skin of the toes became livid and discoloured. These gave a good deal of trouble on account of the slowness with which ulcers that developed where the skin had been discoloured healed. None of my cases developed gangrene.

None of the cases of the first and second types suppurated or showed any inclination to do so, neither did any of them develop whitlow or teno-synovitis of the suppurating type.

About 5 per cent. of the cases had to be evacuated owing to the slowness with which ulcers healed. The ulcers were healthy, and only needed time to recover.

Those cases which commenced as chilblains did not show any signs of vaso-constriction, but almost immediately became red, swollen, and painful. They did not so frequently develop blisters and ulcers, and were more amenable to treatment.

Three cases sent to me as trench foot turned out to be acute rheumatism.

The average time taken for the recovery in the vaso-constrictor type was about ten days; some, especially those which were sent early for treatment, recovered in five or six days, whilst the few that developed ulcers and similar lesions took five or six weeks.

Those cases which had had a previous attack were the most intractable, and one case, which had the scar of a large burn received in early childhood on the dorsum of one foot, gave a good deal of trouble on account of the slowness with which ulcers that developed on that foot healed.

Second and subsequent attacks of trench foot gave more trouble than first attacks, and men who had had one attack should be kept out of the trenches in winter if possible.

Prevention.

The preventive measures to be taken are now well known.

They consist partly of means taken to improve the surroundings of the men, draining trenches, the provision of

trench boards to enable the men to carry out their duties without being exposed to the risk of constantly wet feet.

The provision of waterproof coats to prevent their clothing getting wet in wet trenches, as constant exposure in wet clothing is bound to lower their resisting power to disease.

Special attention is paid to the daily massage of feet and legs with oil, and the provision of a daily change of clean dry socks.

Attempts are made to keep the inside of gum boots dry by the provision of special drying rooms, which as a rule are not very effective.

It is important that units should be relieved from their duties in the trenches as frequently as possible, as it is found that the number and severity of the cases increases in proportion to the length of time spent continuously in the trenches. This is due partly to the confinement and lack of exercise which trench warfare entails.

Treatment.

In those cases which developed in spite of precautionary measures, the following method of treatment in the early stages gave good results:

The patient was kept in bed and the affected parts were carefully covered with lint which had been saturated with spirit (methylated) and wrung out until nearly dry. The moist lint was carefully covered by waterproof material to keep it from drying too quickly, then with a layer of wool and fixed with a bandage. As the lint dried it was moistened and reapplied.

The main points in the use of this method are to take care that the lint is not too wet and that it is thoroughly covered by the waterproof material; if too wet the skin gets sodden, and if not thoroughly covered by waterproof material it dries out too quickly. This application acts as a vaso-dilator and aids in restoring the circulation. It also relieves the pain. It was used in both first and second types of cases with extremely good effect.

After the swelling had subsided massage was employed if the skin remained intact. Ulcers and excoriations were treated with the usual astringent and antiseptic lotions.

Good results in the few cases in which it was tried were got from the use of iodine in chemical combination with oil (liquid paraffin). This was used instead of plain oil for massage and seems worthy of a more extended trial.

In conclusion, the necessity for well fitting foot-gear and the importance of not allowing the use of any form of clothing which may interfere with the circulation through the lower limbs may be emphasized.

TREATMENT OF SECONDARY HAEMORRHAGE FROM THE BUTTOCK BY LIGATURE OF THE INTERNAL ILIAC ARTERY.

BY

W. M. SHEPHERD, M.D., CH.B. EDIN., D.T.M. & H. CANTAB.,
TEMPORARY CAPTAIN R.A.M.C.

It is difficult to realize without having seen the tragedies associated with secondary haemorrhage how real they may be in connexion with wounds of the buttock. A brief glance at the anatomy of the part—the muscle mass, the distribution and anastomosis of the vessels after they emerge from under cover of the sacro-sciatic ligament—makes one pause to think.

The spread of sepsis in this area, the softened tissue, and the granulations render the task of the surgeon no easy one. Again, he is faced with the difficulty as to which vessel the bleeding is coming from. The haemorrhage is generally sharp, the patient is collapsed, and very little more will turn the scale against him.

Plugging of wounds has at all times been found unsatisfactory. The septic material is only daunted up and the condition of the patient rendered worse. A slow oozing persists, or the haemorrhage recurs after removal of the pack, and the patient, worn out by sepsis and loss of blood, finally succumbs. Saline packs—tablet and gauze—have been tried and are occasionally successful, particularly in the less serious type of case. Ligature of the bleeding point is, as in all other parts of the body, the method of choice, but is not always possible. To open up the buttock freely of necessity means a considerable loss of blood, and

even then one cannot always be certain of getting at the bleeding point; and this is particularly true if the vessels have been eroded in the region of the sacro-sciatic ligament and their ends have retracted within the pelvis.

It is here, then, that proximal ligation of a main arterial trunk, so exceptionally justifiable in other parts of the body, has a distinct advantage over other methods of treatment. It effectively controls the haemorrhage, and allows, if necessary, free opening up of the buttock without dangerous haemorrhage, while it does not in any way retard the healing of the parts involved. The hypogastric—internal iliac artery—is the main trunk of supply to the buttock, and is easily accessible in the pelvis. Ligation of this vessel was performed by Annardale for gluteal haemorrhages.

To reach the artery the transperitoneal route is selected, a rectus incision made, and the patient put into the Trendelenburg position. The common iliac artery is then easily identified, the posterior parietal peritoneum incised, and, with very little dissection, the internal iliac can be found just as it bifurcates from the common trunk. A double chronic catgut ligature is passed under the vessel and tied. The position of the ureter and vein has to be kept in mind, and care must be taken to secure the vessel before it divides. On the left side a little difficulty may be experienced, according to the position of the pelvic colon and its mesentery. The posterior parietal peritoneum is sutured with fine catgut, and the abdominal incision closed in layers.

The following cases are illustrative of the condition. A temporary plug was employed for a few hours to control the haemorrhage till the patient recovered from the initial shock.

CASE I.

Pte. W. H., aged 35. Wounded November 16th, 1916; admitted two days later. Gunshot wound of buttock. The patient complained of abdominal pain and tenesmus, and there was evidence of pelvic peritonitis; wound in buttock very septic. X rays showed two shell fragments lying in the pelvis.

Laparotomy: Free fluid in pelvis, much inflammation. Shell fragments lying in recto-vesical pouch; small tear of peritoneum of rectum, but not actually perforated. Fine catgut suture introduced; shell fragments removed; pelvis drained.

The patient improved steadily until November 30th, when he had a severe secondary haemorrhage from the buttock; controlled by pack; intravenous saline given. The right rectus was incised and the internal iliac artery ligated; the buttock wound was opened up, washed out, and lightly packed with eusol gauze; vessels found to be eroded at sacro-sciatic ligament in track of shell fragments.

There was daily improvement until December 5th, when there was a slight recurrence of haemorrhage. The wound was now quite clean and granulating well. A small branch of one of the lateral sacral arteries was found to be oozing; it was ligated with catgut. The patient made an uninterrupted recovery.

This case illustrates the rapidity with which collateral circulation can be established in the buttock.

CASE II.

Pte. S. P., aged 32. Wounded February 25th, 1917; admitted March 1st. Gunshot wound of left groin and buttock, with comminuted fracture of ilium. Shell fragments had been removed at the casualty clearing station, but the wounds were still very septic and were treated with eusol and saline.

On March 3rd, early in the morning, there was severe secondary haemorrhage from the left buttock; controlled by pack, and patient given pituitrin and saline. At 9.30 a.m. the left internal iliac artery was ligated. Pack removed from buttock and wound irrigated with eusol and explored with finger, but not opened up, as patient's condition was not good. Track went down to sacro-sciatic ligament in region of vessels; it was lightly packed with eusol gauze.

The patient made a good recovery; there was no recurrence of haemorrhage, and the buttock wound healed well.

CASE III.

Pte. G. E., aged 21. Wounded March 5th, 1917; admitted the following day. Gunshot wound of right thigh and buttock; wounds very septic. X rays showed shell fragment lying in region of sacro-sciatic ligament. Wound excised; foreign body removed, from close proximity to gluteal vessels; eusol gauze.

March 9th. Smart secondary haemorrhage; controlled by pack. Right internal iliac artery ligated. The buttock wound was opened up and clot washed out; vessels eroded at point of emergence from under cover of sacro-sciatic ligament; light pack of eusol gauze introduced.

The patient made an excellent recovery; there was no recurrence of haemorrhage, and the buttock wound cleaned up and healed well.

CASE IV.

Pte. W. H. (Prussian Infantry). Wounded April 3rd, 1917; admitted April 6th. Entrance and exit wounds of right buttock in line of gluteal vessels; wounds mildly septic—opened and drained.

April 9th. Smart secondary haemorrhage in early morning; controlled by pack, and patient given pituitrin and saline. At 9.30 a.m. the right internal iliac artery was ligated; buttock wound opened up—much septic clot, muscles soft and friable, gluteal vessels eroded and ends retracted under the sacro-sciatic ligament. A light pack of eusol gauze left in buttock wound.

The patient made a complete recovery; there was no recurrence of haemorrhage, and the wounds healed well.

CASE V.

Driver J. W., aged 25. Wounded April 28th, 1917; admitted May 1st. Gunshot wound of left buttock. Large entrance and exit shell wound which had been excised at the casualty clearing station. Track of wound crossed line of gluteal vessels. Wounds very septic, edges gangrenous. Treated with Carrel's tubes.

May 3rd. Severe secondary haemorrhage in early morning; controlled by pack, and patient given pituitrin and saline. 9.30 a.m.: Intravenous saline given; left internal iliac artery ligated. Clot washed out of buttock wound—vessel found eroded beneath sacro-sciatic ligament; saline pack introduced into buttock wound. Dressed on the third day—buttock wound now clean and granulating. General condition of patient much improved. There was no recurrence of haemorrhage; the buttock wound granulated and healed well.

FRAGMENT OF SHELL IN THE ARTERIAL CIRCULATION.

By CAPTAIN C. S. O'NEILL, M.D., R.A.M.C.(T.C.),
OFFICER COMMANDING NO. — MOBILE X-RAY UNIT.

THE following interesting case is put on record owing to the great rarity of the condition and its interest from a radiological point of view:

Sgt. P. was wounded at 7 p.m. on August 7th, 1917, and was admitted to a casualty clearing station on the morning of August 8th in a very collapsed condition with a running pulse of 128 a minute and wounds in the left posterior axillary line, fifth interspace, left lumbar region, and left thigh. On admission the patient was too ill for a thorough clinical examination of the chest, but it was found that the heart was not displaced and that there was well marked pericardial friction.

On August 10th the patient was moved to the x-ray room and screened. It was then found that the shadow over the left chest was uniformly obscure and dense, and practically no movement was seen in the left diaphragm, which was depressed and flattened to an obtuse angle. The right chest and diaphragm were normal in appearance. The most striking picture was seen in the cardiac region. The shadow of the heart was much to the right of the mid-line, which would be expected with a large haemothorax which gives the picture of a combination of great obscurity of the chest, depression and fixation of the diaphragm on the affected side, with dislocation of the heart shadow to the unaffected side. However, in this instance not only was the heart shadow more to the right than normal, but it was increased in breadth, and was globular in shape. The cardio-hepatic angle was obtuse and the muscle of the right side of the heart could be differentiated from the extreme edge of the heart shadow, and the diagnosis of pericardial effusion was made. About one inch above the base of the heart and two inches from the right border and two and a half inches deep, a foreign body was made out within the heart shadow with an extraordinary movement. The black shadow of the foreign body, some 2 cm. long with a maximum breadth of 0.6 cm., could not be separated from the heart shadow whatever the incidence of the x rays. The movements seen were a downward movement with the mediastinal respiratory movement, a lateral movement with systole to the right, and a flail-like movement, with the base of the flail to the right side. These movements were synchronous with the heart beats, giving a curious rotary effect. The diagnosis was then made that the foreign body was within a chamber of the heart, probably within the left ventricle, and had one end of it fixed under a valve flap. Half an hour after returning to the ward from this examination the patient called attention to his left leg, which was found to be blue in colour and cold from above the knee to the foot. One hour later the leg appeared to be normal again.

On August 11th the wounds in the left lumbar region and left thigh demanded urgent surgical interference owing to the development of signs of gas gangrene, and on his way to the operating theatre the patient was again screened with a view to more accurate localization of the fragments in the thigh and lumbar region. His chest was also screened, and although otherwise the picture was identical no trace of the foreign body in the heart could be seen, and on rapid examination of the course of the thoracic and abdominal aorta it was found that the missile must have passed through the aortic valve and was lying in the abdominal cavity 2½ in. deep from the anterior abdominal wall, 1 in. below and 1 in. to the left of the umbilicus. No movement was seen and the foreign body was apparently,

within the aorta at its bifurcation. On the morning of August 12th the patient's condition did not seem the worse for the operations on his thigh and loin under gas and oxygen, and the aspiration of 6 oz. of blood from the left pleural cavity. Pericardial friction was well marked, no increase of cardiac dullness could be made out, there was resonance in the left axilla, and the breath sounds were generally harsh on the left side. He died at 6.25 p.m. this day.

Necropsy.

There was surgical emphysema of face, neck, and thorax. The left chest contained a small amount of blood. There was an entrance wound in the left posterior axillary line. The pericardium contained a small amount of blood and a small tear on the posterior inferior aspect. There was an exudate of fibrin over the anterior and left lateral walls.

There was a small hole, surrounded by haemorrhage into the myocardium, on the posterior wall of the left ventricle. The interior of the left ventricle was clear except that there was a ragged tear on the septal wall, and the chordae tendineae of the aortic valve were also torn. The heart muscle was very pale and full of gas.

The liver and spleen were very congested and full of gas. In the left lung was a small haemorrhagic infarct with fragments of indriven rib; the right lung was normal.

The foreign body was found at the bifurcation of the left common iliac artery surrounded by dark red clot; the intima was apparently undamaged. There was no tear of the intima at the aortic bifurcation.

Since the second time of screening, on August 11th, the missile must have moved down the left common iliac artery and become lodged at the bifurcation. At the time of the second screening there was no difference noted in the femoral pulses, but the missile most probably moved down the aorta, passing through the aortic valve within half an hour of the first screening, when the phenomena in the left leg were noted. The patient died of general gas gangrene after having lived five days with a piece of shell free in his arterial circulation.

THE STORY OF A TOOTH-PLATE: AN UNUSUAL WAR INJURY.

BY

GORDON TAYLOR, M.S.LOND., F.R.C.S.ENG.,
TEMPORARY MAJOR, R.A.M.C.; SENIOR ASSISTANT SURGEON,
MIDDLESEX HOSPITAL.

DURING the battle of the Somme a soldier was buried in his shelter by a large shell. He was dug out from amongst the débris in an unconscious state, and ultimately placed on a hospital barge, and thus conveyed to the base. When he recovered consciousness on the barge, one of his first requests was for the artificial tooth-plate which he had been wearing when he was rendered unconscious by the shell explosion. The denture—an upper one—was produced from his wallet by the attendant orderly, but the patient, remarking its size and the number of teeth, quickly declared his doubt as to it being his, or if it were, he assured those in attendance that it must have been broken, and that part of it was missing.

The patient had also shown some signs of a fracture of the skull, and to this was ascribed the difficulty in swallowing of which he complained. No radiogram was apparently taken, and he was speedily evacuated to England, and admitted into one of the auxiliary military hospitals at Eastbourne. The man's story led to an investigation of the denture, which showed clear evidence of having been fractured across its palatal and alveolar portions. Examination with the screen revealed the presence of a foreign body in the thorax, and an x-ray picture showed a denture with two teeth opposite the middle piece of the sternum.

I was asked by the medical staff of the hospital to try to remove it. The use of a Brünig's oesophagoscope fitted with a Hill's tube made it possible to obtain a good view of the offending denture, and it was easily extracted *per vias naturales* by means of an Irwin Moore's forceps. So far as the gullet was concerned, recovery was quite uneventful, but the original diagnosis of a fracture of the base of the skull was only too surely confirmed by the development of a pulsating exophthalmos, which was successfully treated by ligation of the internal carotid artery by an able surgeon in Eastbourne.

The case is of interest in that a fracture of an upper dental plate was produced without any injury of the superior maxilla. This injury is by no means unique, for I have heard of similar accidents in the present war, but

the story of this particular case, where one of the fragments of the broken denture was actually swallowed by a patient rendered unconscious by the same injury that fractured the dental plate, must be almost without parallel.

ABSENCE OF THE RIGHT PINNA AND RIGHT TONSIL, WITH RIGHT FACIAL PARALYSIS.

BY

JAMES J. HEALY, CAPTAIN R.A.M.C.

SOME little time ago an extraordinary case of congenital deficiency came under my care. A recruit (W. G. B., aged 18 years) was brought to me, owing to the absence of the right ear.

It was quite evident that the right pinna had never developed. Smooth skin completely covered the site where the pinna should have been. There was no sign of any scar, or of any external auditory meatus. The helix was represented in a rudimentary manner as a slightly elevated ridge of cartilage beneath the skin. Darwin's tubercle was well marked and better developed than any other portion of the cartilage. A rudimentary tragus was present in the usual position, and caused a very slight elevation of the skin. Posteriorly to the tragus, the outer end of the cartilaginous external auditory meatus could be felt subcutaneously.

The left ear was normally developed. Tests of hearing gave the following results:

Left ear normal in all respects.

Right Ear.—(1) Weber's test, positive. (2) Rinne's test: (a) Air conduction just perceptible; (b) bone conduction normal. (3) Spoken voice: (a) Normal voice heard at 18 inches; (b) whispered voice not heard. (4) Politzer inflation gave sensation of cracking in the ear.

Conclusion: Partial deafness of right ear due to obstruction of external auditory meatus. The middle ear and Eustachian tube were intact.

The face showed paralysis of the right side, complete in all regions, except the angle of the mouth, where slight muscular effort was perceptible. It was impossible to make out whether the stylo-hyoid and posterior belly of the digastric were intact or not, but the hyoid bone seemed to move evenly and normally.

Sensation of both sides of the face was intact, but the vasomotor control of the right side was lost. Eyesight was poor; vision was $\frac{3}{16}$, myopic in both eyes—with chronic conjunctival thickening in the right eye due to its constantly exposed condition.

The right tonsil and right anterior pillar of the fauces were absent. There was no evidence or history of removal. The palato-pharyngeus muscle was intact, and the tongue was quite normally developed. No difference in the sensation of taste between the two sides of the palate could be detected with acid, bitter, salt, sweet, and pungent solutions. Saliva was seen issuing from the mouths of Stenson's and Wharton's ducts, and no diminution in the amount of flow could be detected on the right side.

The family history contained nothing of importance. The man is an only son of a family of seven, the fourth child of a normal father and mother.

It is worth noting that there was no injury during parturition. No instruments were used at his birth. The paralysis was present from birth.

Summary.

1. There was overgrowth at the outer end of the external auditory meatus, shown by the closing in of its margins.
2. Diminished growth at the outer end of the hyo-mandibular cleft or facial nerve region, as evidenced by the almost complete absence of the pinna.
3. Diminished growth in the soft palate or fifth nerve region, as evidenced by the absence of the palato-glossus muscle or anterior pillar of the fauces.
4. Diminished growth in the second cleft or glosso-pharyngeal region, as shown by the absence of the tonsil.
5. Lack of development of, or a lesion causing complete atrophy of, the facial nerve.

Observations.

Points for consideration are:

1. The facial nerve is chiefly concerned with the hyo-mandibular cleft, but overflows to the other regions involved.

2. The condition may be primarily one of nerve absence or nerve lesion in mid-embryonic life, with secondary non-development or partial development of the mesoblastic structures due to the loss of nerve control.

3. The muscular effort perceptible at the angle of the mouth may be due to the nervous supply of the hypoglossal.

The FitzPatrick Lectures

ON

MEDICINE IN ENGLAND DURING THE REIGN OF GEORGE III.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS
OF LONDON.

By ARNOLD CHAPLIN, M.D., F.R.C.P.,

PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

(Concluded from p. 690.)

VIII. PHYSICIANS WHO DETERMINED THE ADVANCE OF MEDICAL KNOWLEDGE.

FROM the general topics discussed in the earlier part of his lectures Dr. Chaplin went on to give an account of the individual work of physicians during the reign of George III, considering first the work of those who contributed to the advancement of medical knowledge and then giving an estimate of the activities of those who widened the boundaries of general science.

An idea of the scope of medicine taught during the first thirty years of the reign could, he said, be formed from the work of Dr. George Fordyce of St. Thomas's Hospital, the *Elements of the Practice of Physic*, which appeared to be the chief students' textbook of those days. For thirty years Fordyce lectured on medicine at his house in Essex Street, Strand, and his book might be taken to be the substance of what he was accustomed to teach. Its first hundred pages were devoted to the natural history of the human body—physiology—the remainder to the symptoms, distinctions, prognostics, and cure of fevers and inflammations, all the morbid conditions physicians were called upon to treat being included under these heads. In accordance with the doctrines of the time, little or no attempt was made to distinguish and classify the various forms of fever.

The elder Heberden was the great prototype of the modern clinical physician, and the connecting link between Sydenham on the one hand, and Bright, Addison, and Watson on the other. His *Commentaries*, published after his death in 1801, contained the results of his study and experience, extending over sixty years. So sound was his doctrine, so cautious its treatment, and so endowed with excellent common sense that much of it would require little editing at the present day. It contained no fantastic theories, no appeal to metaphysical disquisitions, but simply the results of the close study by an acute observer of signs and symptoms of disease at the bedside. Dr. Chaplin referred next to Sir George Baker, a former president of the College, whose essay on lead colic might justly be quoted as a model of inductive logic.

Towards the end of the eighteenth century the existing order of clinical physicians, which depended entirely upon knowledge gained at the bedside, was beginning to be replaced by a race who enlisted the sciences of chemistry, anatomy, and physiology in order to elucidate many problems. The desire to profit from knowledge gained by an examination of diseased parts on the *post-mortem* table received its first stimulus in England in the publication, in 1769, of Dr. Alexander's translation of the great work in which Morgagni for the first time directed anatomical knowledge to the service of medicine. The study of morbid anatomy was carried on and advanced in France by Bichat; but it was Matthew Baillie, great as a physician and great as a morbid anatomist, who was the father of medical pathology. His celebrated book on *The Morbid Anatomy of Some of the Most Important Parts of the Human Body*, published in 1793, was the first English treatise on morbid anatomy. Baillie summarized the purpose of his work under the four following heads: "(1) To explain the changes of structure arising from morbid conditions; (2) to distinguish between morbid changes which have been generally confounded; (3) to detect diseased alterations in

the organization of parts which are but little or not at all known; (4) from the observation of morbid structure theories taken up hastily about disease will be occasionally corrected." The chief characteristics of the work were its conciseness and accurate observation; the plates, produced after the appearance of the book, afforded unimpeachable evidence of Baillie's unerring accuracy. Baillie scarcely lived to see the full fruits of his pioneer work, but looking back we could detect in it the beginnings of the science of pathology.

At about the same period the sciences of chemistry and pathology were beginning to be seriously applied to the art of medicine. Chemistry had received considerable attention from certain London physicians, one of the first of whom was Dr. William Saunders of Guy's Hospital, who lectured on chemistry from 1766 onwards. He assisted Sir George Baker in the chemical part of his inquiry into lead colic. Berzelius greatly stimulated study of the subject of animal chemistry, and a translation of his essay on the *Progress of the Present State of Animal Chemistry* was published by Young. It was, however, Dr. William Prout who was the first physician to bring a sound and comprehensive knowledge of animal chemistry to the aid of practical medicine. Prout was one of the famous quartet of great scientists, the others being Young, Wollaston, and Wells, who adorned the medical profession towards the end of the reign of George III; but unlike the other three, he added to his great scientific attainments practical ability as a physician. He began to lecture on chemistry in 1813, and many fundamental truths concerning metabolism were first stated by him, among them the facts that urea was formed in the blood and merely excreted by the kidneys, and that the healthy stomach contained always a percentage of hydrochloric acid. He also was the first to enunciate the doctrine of "secondary assimilation," but his views were to a certain extent perjured by Giessen and Justus von Liebig, and given to the world under the high-sounding title of the "metamorphoses of tissues."

Dr. Chaplin turned aside to speak of the work done in dermatology by Willan—who was the first to place the classification of diseases of the skin on an anatomical basis—and of the progress in midwifery achieved during the reign. Apparently no definite instruction in midwifery was given in London until 1739, when Smellie began a course of lectures. In the same year Sir Richard Manningham established a ward in the Westminster Infirmary for lying-in women, and soon afterwards lying-in hospitals began to be erected, of which the earliest was the British Lying-in Hospital, founded in 1749, with William Hunter as its first physician.

IX. PHYSICIANS WHO CONTRIBUTED TO THE ADVANCE OF SCIENCE IN GENERAL.

Thomas Young.

Reverting then to the quartet of physicians superlatively great in science, Dr. Chaplin spoke next of Thomas Young, of whom he said that it was almost impossible to realize the extent and depth of his mental capacity. Physics, classics, mathematics, Egyptology, philology, music, biography, and actuarial science, he made them all his own; with him there was never any hurry in the acquirement of knowledge, each subject in turn was taken up and deliberately exhausted before another was attempted. He was fortunate in receiving a legacy of £10,000 from his uncle, together with a house and its contents in Norfolk Street, Strand—bequests which relieved him of the necessity of drudging for a living. After visiting Edinburgh, Goettingen, and Cambridge as a student, he was in 1802, when in his twenty-ninth year, appointed to deliver lectures on natural philosophy at the Royal Institution, and at about the same time published his undulatory theory of light, which the scientific world, with the exception of Arago and Fresnel, hesitated for some years to accept, owing largely to Brougham's attack. In the domain of Egyptology, in which he began really to interest himself about 1816, Young met with even more opposition, and had to see much of his work pilfered by others, the chief offender being the great Champollion. There was, however, no doubt that Young could claim priority over Champollion in the discovery of phonetic hieroglyphics from his study of the Rosetta stone. Some of the failure of Young to obtain recognition for his work in science was to be

attributed to faults of his own; he appeared to resent the intrusion of others into his intellectual territory, and his style was somewhat obscure and not a little caustic. As a physician Young was not successful either in practice or as a writer; his *Treatise on Consumptive Diseases* was a compilation, and his *Introduction to Medical Literature*, though it displayed a vast amount of learning, was not in other respects remarkable. Still, Thomas Young rose above all the great men of science produced in the reign of George III in mental stature and comprehensiveness of intellect.

William Charles Wells.

For William Charles Wells, the next name in the quartet, success in the shape of social fame and emolument never came. Of him Dr. Chaplin said: He began his career in London penniless, and after sixteen years of toil was unable to command an income of more than £307 from all sources. Ill health clogged his steps; in his forty-third year he was seized with a slight stroke, and henceforth, for him, it was a grim fight against time to finish the work he had designed. But in spite of these disadvantages he laboured on bravely in his humble lodging in Serjeant's Inn, scarcely known to any but five close friends, and when his work was accomplished, he desired only the modest epitaph that "he had tried to extend the boundaries of knowledge." Shrewd judges of mankind, such as Brodie, described Wells as one of the most remarkable intellects of the age, but his peculiar temperament, and somewhat cold scientific type of mind did not lend themselves to the showy mental exploits beloved by the multitude.

In the sphere of natural philosophy the name of Wells will be for ever honoured. It was his good fortune to investigate and establish the laws which govern the formation of moisture in the air, and although physical chemistry has advanced in all directions, the fundamental principles enunciated by him have never been seriously challenged. For this work Wells was awarded the Rumford medal in 1814, and since then his name has been inseparably connected with the subject. Previous to his work it had been supposed, since the days of Aristotle, that dew was formed in the lower atmosphere in consequence of its moisture being condensed by means of cold, and that in its formation cold was produced. Wells became doubtful of the accuracy of this view, and accordingly carried out a series of experiments in the garden of Mr. James Dunsmore, a merchant friend, who lived in Surrey, three miles from Blackfriars Bridge. To this country house Wells betook himself late in the afternoons, and, with varying intervals caused by ill health, prosecuted his experimental work during the nights, returning in the early morning to his house for the day's work. In his *Essay on Dew* he pays an affectionate tribute to his friend Dunsmore for allowing him to use his garden "at considerable inconvenience to the members of the family." Wells also conducted experiments in Lincoln's Inn Fields when increasing infirmity rendered it impossible for him to go into the country.

Wells used pieces of wool of known weight, and these he weighed again after they had absorbed the dew in various situations and under varying conditions of atmosphere. He thus became acquainted with the laws which govern the deposition of dew. For instance, he found that the exclusion of the sky from the wool diminished the quantity of dew formed, that more was deposited on wool when on grass than when placed on gravel, mould, bright metals, or when suspended in the air. Having obtained these data, he then investigated the part cold played in the formation of dew, and at this stage his original discovery was made. He found, as others had done before, that the temperature of the ground was higher than that of the air above, that passing clouds cause a rise of temperature, and, what was of the utmost importance, that certain substances placed on the ground took on a lower temperature than the ground itself. From these facts he deduced his theory that "Dew is the production of a preceding cold in the substances upon which it appears." He also established the fact that the production of water from the atmosphere actually produces heat. All this was contrary to the view, hitherto accepted, that dew was formed by the cold of the night, and that in its formation cold was produced.

Such was the work of Wells. It is a melancholy picture,

this last effort of his, feverishly labouring to finish his experiments, with water-logged legs, and the agony of cardiac asthma ever present; spending nights in Dunsmore's garden which should have been devoted to repose, and then hurrying back to town in the early morning to write down his results lest death should claim him ere his task was completed. Surely few scientific workers have battled so bravely with adverse conditions.

The medical work of Wells has not, perhaps, received the consideration it deserves. His chief claim to distinction in this sphere rests on the papers he communicated to the Society for the Improvement of Medical and Chirurgical Knowledge, in which he dealt with the occurrence of albumin in cases of dropsy. His first paper, read on November 4th, 1806, related only to cases of dropsy following scarlet fever. This phenomenon had been observed by Plenck of Vienna, Cruikshank, and Berserius long before, but it was Wells who noticed that blood and albumin were present in the urine in these cases. He also established the fact that the dropsy occurred in the upper parts of the body, and described—without, however, giving them a name—the uraemic seizures to which such cases are liable. He found evidences of inflammation present in all the abdominal organs, including the kidneys, and inferred that the process was essentially inflammatory in origin.

On June 4th, 1811, he read another paper before the same society, in which he pointed out that albumin was to be found in cases of dropsy other than scarlatinal, and drew a distinction between hydrothorax, ascites, and dropsy of the skin, in that the two former, if primary, did not have albumin in the urine. This was the first attempt to differentiate between the various forms of dropsy. The point was used with great advantage by Blackall, who, writing two years later, still further elaborated it, but the merit of pointing it out belongs to Wells alone. In support of his contentions, Wells quoted two *post-mortem* examinations, in one of which "the kidneys were much harder than they usually are, and the cortical parts were thickened," while in the other he says, "the kidneys were larger and softer, and on the outside were several vesicles." He gave the credit of the discovery of albumin to Cruikshank who mentioned it in 1798, but points out that he had discovered it independently in 1799. Wells had, therefore, established the fact of albumin in dropsy. He had differentiated the forms of dropsy in which albumin was found. He had even indicated that the kidneys were diseased, but he failed to point out the causal relations between the two. This momentous clinical fact had to await the advent of Richard Bright, but it was Wells who prepared the ground. To complete the consideration of the work of Wells it is to be remembered that Darwin himself, in his historical introduction to the *Origin of Species*, gives to Wells the credit of having been the first to enunciate the principle of natural selection, in a paper read before the Royal Society in 1813. Altogether Wells was one of the great men of the profession during the reign of George III; a man of great scientific ability, with a lofty conception of duty, and with an adherence to truth which never swerved.

Wollaston.

William Hyde Wollaston was so little associated with the practice of medicine that his work can scarcely be considered from that point of view. Very early in his career he definitely severed his connexion with medicine, owing, it is said, to his unsuccessful application for the post of physician to St. George's, and henceforth devoted himself entirely to science. Some of his scientific work, however, related to problems in medicine, and in this field he initiated inquiry which led to important results. He was one of the first to study the composition of calculi and other abnormal constituents of the urine; work which, no doubt, paved the way for the further extension of the subject by Prout and Marcet. He also explained the phenomenon of hemianopia, and demonstrated the partial decussation of the fibres in the optic commissure. But with these exceptions the whole of the scientific work of Wollaston belonged to physics, chemistry, and metallurgy. He discovered rhodium and palladium, and devised a process for rendering platinum malleable. He was the first to see the dark lines in the spectrum, since known under the name of Fraunhofer's lines, but failed to appreciate their true significance. As a point of peculiar interest at the present time, it may be

mentioned that Wollaston invented the periscope, an instrument so frequently in our thoughts to-day.

Excessively cautious, fearing to advance by bold deductions, Wollaston constantly allowed others to reap where he had sown. In this way he lost his claim to be one of the first sponsors of the atomic theory.

CONCLUSION.

Dr. Chaplin concluded his review of the progress made in medical knowledge during the reign of George III in the following words:

We have seen that soon after the beginning of the reign a distinct revival of activity in its study became evident. We have shown that, at first, the revival manifested itself in an increase of clinical knowledge gained almost entirely from observation of symptoms during illness. We have pointed out the manner in which the obstacles to the advance of clinical medicine were surmounted by the application of the sciences of pathology, physiology, and chemistry, which, towards the end of the eighteenth century, had been placed upon a sound foundation. We have also devoted space to the consideration of those physicians whose activities were mainly scientific. In all this the main features of the spirit of the eighteenth century, which laboured unceasingly for the emancipation of the human intellect, for freedom of thought, and for inquiry on scientific lines, can be clearly observed. We owe to the physicians of the age of George III an immense debt for the excellent foundations they built, often with rough and improvised tools. Like the Georgian architecture, the Georgian silver, and the Georgian glass, they were large and solid, and were fashioned to stand the test of time. Men of the stamp of Hunter, Baillie, Prout, and Willan flung open the portals of medical science, through which their descendants have passed to realms of spacious and accurate knowledge.

MEDICAL, SURGICAL, OBSTETRICAL.

FIBROID UTERUS TREATED BY X RAYS.

THE patient, a married woman aged 42, came to me in February, 1917, for a fibroid causing discomfort from its size, with constant backache and pressure symptoms. She had a bilobed fibroid of the whole wall.

During three months she received eight x-ray treatments, each of two to three pastille doses, filtered. The monthly periods were regular before treatment. Under x rays she had one heavy followed by two ordinary periods, and they have stopped entirely since the sixth treatment, now five months ago.

The fundus was 4½ in. above the pubes. During treatment it was reduced to 2½ in., and three months later was only 2 in. above the pubes. In width the tumour was reduced from over 5 in. to 4 in. during treatment, and since then has become reduced another inch.

The front wall was bulged out so that the distance from pubes to umbilicus was 7½ in. at first; this has come down to being flat, and now measures 6 in.

Except during the first monthly period, she has not been in bed for a day since treatment was first begun; pressure symptoms are relieved and the backache is gone. The patient is well and strong and very pleased with the final result.

This is the fourth case of fibroid I have treated in a similar manner, and all with remarkably good results. In one case the menopause was brought about, in the two other cases the periods were only reduced in quantity.

FLORENCE A. STONEY, M.D., B.S.

HYPERPYREXIA IN ENTERIC FEVER.

THE case of hyperpyrexia in enteric fever recorded in the JOURNAL of October 20th by Dr. Fonseca recalls a case complicated with pneumonia I saw a few years ago. The temperature was taken every two hours.

H. S., a girl aged 15, who was abnormally fat for her age, was seen for the first time on January 29th. Her mother said she had been ill for a week. Her face was flushed; she complained of headache; pneumonia was present at the base of the right lung. The temperature was 103.6°.

On the following day the temperature was 104°, and there was occasional delirium at night; pulse 140; haemoptysis. The next two days the temperature remained at 104°; there was still occasional delirium, and haemoptysis occurred on each day; pulse 130.

February 2nd. Temperature 103.6°; delirium constant; pulse 130, respirations 40; tympanites, spots appeared on abdomen.

February 3rd. Temperature 104°; delirium constant; pulse 130, respirations 52.

February 4th. Temperature 104.2°; delirium constant; pulse 140, respirations 72. Calomel was given.

The patient was sponged every day, which brought the temperature down, but it soon went up again.

February 5th. Temperature 105.4°; delirium constant; pulse 140, respirations 67. The temperature went up to 105.8° and then suddenly, after the patient had been sponged, it jumped to 109°, when the patient died. Ten minutes after death the temperature was 106°.

Reports of Societies.

VALUE AND LIMITATIONS OF SANATORIUM TREATMENT FOR TUBERCULOSIS.

THE discussion on this subject (see BRITISH MEDICAL JOURNAL, November 17th, p. 650, and November 24th, p. 690) was continued at the meeting of the Medical Society of London on November 26th, when the President, Sir ST. CLAIR THOMSON, was in the chair.

Dr. CAMAC WILKINSON, while thinking sanatoriums invaluable and indispensable in the treatment of certain forms of tuberculosis, expressed the opinion that the present system could only touch the fringe of the disease. The victims who could not pay for their own treatment numbered at least 250,000 to 300,000. After the war, including soldiers and dependants, there would be 300,000 needing treatment. There were 11,000 beds in sanatoriums, and all authorities now admitted that each case needed, on an average, six months' residence. Thus there would be room for 20,000 every year. This meant that 6.6 per cent. of these victims could have treatment in one year, and 50 per cent. of these were dead in three to four years, so that benefit was chiefly limited to 3.3 per cent. of the total. Thus 93.3 per cent. of the cases needing treatment could not enter a sanatorium for at least a year. In other words, 20,000 cases were treated and 280,000 left out. The problem should not be discussed as it affected a small proportion of victims; no system could be called a success which could not offer immediate, expeditious, economical, convenient, and effective treatment to the majority of sufferers. The cost might be stated in three distinct ways: (1) The bare cost of treatment, which would certainly be £50 for each case, representing £1,000,000 for 20,000 cases; (2) every man was worth at least £50 a year to the State, many ten times that amount—this represented a further dead loss of £500,000; (3) the economic loss from loss of occupation and wage, varying from £50 to £150 per case, represented another £1,000,000 to £3,000,000 per annum. The total loss from prolonged residence in sanatoriums was from £2,500,000 to £4,500,000 every year. He disagreed with Dr. Lister's opinion that the tubercle bacillus was a harmless pest to most of us, considering that it caused one-third of the total deaths of men and women occurring in the prime of life.

Dr. CRACE CALVERT thought that statistics were not of much use, as it was difficult to get particulars of patients who had gained permanent benefit, most of whom did not report again to the sanatorium. Every patient should be given sanatorium treatment except those suffering from advanced or marked disease. He thought sanatorium should be given before home treatment. Sanatoriums

Diagram of fundus uteri to scale.

were of value because (1) a patient came under the care of a physician who could advise him on all conditions of his life; (2) he could be taught how to regulate his life and activities; (3) the moral effect was good; (4) the educational value was useful; (5) in the majority quiescence of the disease was obtained and this might go on to arrest. The unsuitable cases were the acute, auto-inoculations, alcoholics, and patients of the flabby type. Three months was the least which should be spent in a sanatorium; six months was preferable. With regard to after-care, he advocated the starting of colonies along the lines of the Cambridge after-care colony.

Dr. HENRY ELLIS said that sanatoriums, from a national point of view, were a failure; the number of beds was increased to 11,000 without a drop in the death-rate; but from the point of view of the individual they were of enormous value. Sanatorium figures were very unsatisfactory, as they were limited to cases showing tubercle bacilli in the sputum, and cases were not counted until there was definite evidence of tissue destruction. There should be separate sanatoriums for patients in Class I and those in Class II. Lighter treatment was required along the lines of the convalescent home. Even a short time away from work would improve enormously the condition of the tuberculous. Resistance was the main factor, loss of which was due to overwork, poor food, illness, and home conditions. Statistics showed that the mortality among the independent classes was greater than among the working classes. More than 50 per cent. of the patients died within six months of notification. It was known that sanatorium treatment was good for early tuberculosis, but it was eliminated from the statistics; it was known that delay in sanatorium treatment was fatal to success, yet there were waiting lists; it was known that environment, by lowering resistance, produced the disease, but nothing was done to make environment better; it was known that early recognition was the keystone of success, but had anything been done to investigate how early recognition might be made more simple and certain?

Dr. JANE WALKER thought that the results of sanatorium treatment were disappointing if regarded from the physical point of view, but the social and educational factors were of great value. The treatment of tuberculosis in children was very important. Infection occurred at a very early age; previous history could be obtained more easily, and tuberculous children were much more intelligent than others. Boarding schools for working-class children were urgently needed. Working-class patients should return to their previous work, as in this way much of their anxiety was relieved. Means for treatment of surgical tuberculosis in adults was much needed.

Dr. HECTOR MACKENZIE said it was impossible to tell with certainty whether any particular case of consumption was curable. Sometimes the best efforts ended in failure on account of the virulence of the organism or the low resistance of the patient. Sanatoriums should be reserved for early cases, those with a slight and limited lesion, but these were not often met with in practice. Immediate results should be most marked among the poorer classes, where sanatorium surroundings differed most from home conditions. Ultimate results should be better among the well-to-do. The sanatorium was only one means of attacking the problem, and was designed for hopeful cases, but there was need for permanent institutions for the incurable advanced cases and for the dying.

Dr. NEVIN ROBERTSON said that the sanatorium was the best existing method of raising resistance. The limitations were financial, patients not having enough money to get treatment for a sufficient length of time. Of 1,141 patients who had been in Benenden Sanatorium from 1907 to 1914, 36 per cent. were on full work, 3 per cent. on partial work, 11 per cent. on no work, 41 per cent. were dead, and 6 per cent. were readmitted. Of 563 cases traced at the end of 1914 who had left in the years 1907-11, 20 per cent. were on full work, 2 per cent. on partial work, 2 per cent. on no work, 63 per cent. were dead, and 12 per cent. had been readmitted. There were two alternatives—earlier diagnosis on the one hand, and after-care colonies and improvement of housing and environment on the other. He thought the results in early cases were often permanent. Bad housing was only one factor; others which lowered resistance were alcoholism, syphilis, overwork, dissipation, poverty, and lack of food. The people should be taught to be conscientious in regard

to health, and the general practitioner had this field to himself. The value of sanatorium treatment depended upon (a) discipline and the healthy life of the patient, (b) healthy environment. The limitations were due to the absence of a sanatorium life in the general community. In removing the limitations there were two lines of action: (1) prevention of the disease and (2) prevention of infection. For the prevention of the disease there must be thorough education of the people in the laws of health through preaching the gospel of health in schools, homes, and pulpits, and the conditions of bad environment must be removed by improvement of housing, factories, and workshops. Chronic and advanced cases often caused massive infection. There were two ways of preventing infection: (1) by early diagnosis and treatment, so that the cases which reached an infective stage were diminished, and (2) by isolation of all infective cases from beginning to end of the disease. The dispensary should be a place for examination of contacts and for their supervision.

Dr. MURRU said that much of the confusion and uncertainty as to the best methods necessary to combat tuberculosis was due to want of clear ideas as to the real causes of the disease. The question whether tuberculosis was a social or infectious disease must be decided. If it were an infectious disease every measure of inoculation and injection and internal administration of antiseptics would be legitimate and essential. But it was inconsistent while believing in infection to swing round and attack poverty, alcohol, bad housing and low wages, and other social evils. He was convinced consumption was more a product of vicious environment than of infection, that the mental factor was more important than the microbe factor, that man created soil favourable to infection, and that without such suitable soil there could be no infection. Study of the mortality-rate of phthisis in England and Wales for forty years, from 1875 to 1915, showed that during the last twenty years (1895 to 1915), in spite of active propaganda and great efforts to destroy infection, the rate of mortality had not declined so much as in the previous twenty years when no such efforts were made. On the other hand the very fact that improved well-being of the people had been the means of reducing the mortality of phthisis was a proof that it was more a social and economic disease. The success of sanatorium treatment had proved this, for if the provision of fresh air, food and rest, and healthy environment had brought about a cure or arrest of consumption, then the want of such provision or insufficiency must surely be the cause of it. Home treatment was more or less a failure. When due allowance was made for the possibility of spontaneous arrest of the disease, still sanatorium treatment had undoubtedly saved many lives. The value of sanatorium treatment depended among other things upon the nature of cases admitted, the management and discipline among the patients, and upon the personality of the physician. The limitations of sanatorium treatment arose from many causes. Cases were not got early in spite of compulsory notification. Patients did not stay long enough or had not the patience and perseverance to continue treatment. Some had drawn upon their vital powers too freely in their youth or were handicapped by family predisposition; hence their failure to respond to treatment. Sanatorium treatment had its limit; it could not prevent tuberculosis or cure every case. It was the first link in the treatment, and showed the patient how to live the right life. It was for the nation to devise larger and more comprehensive measures, such as farm colonies, industrial settlements, garden cities, etc., to meet the needs of both the disabled soldier and the disabled consumptive.

Dr. JOHN SORLEY thought that undue importance was attached to physical signs in classification. Early cases only were to be sent to sanatoriums, but he had patients with cavities doing seventy hours' work a week, and patients with the disease in an early stage with a few crepitations at an apex going downhill quickly. The death-rate of those who did not avail themselves of sanatorium treatment was 84 per cent. higher than among those who did.

Lord GLENCONNER, President of the National Association for the Prevention of Consumption, said that much progress had been made, not in cure, but in investigation, and in care in providing healthy surroundings for our working people. He was favourably impressed by all he had seen

in sanatoriums. Only the fringe of the problem was touched, but in time to come that margin would become larger.

Dr. JAMES STEWART also spoke, and Dr. LISTER replied briefly.

Reviews.

THE LIFE OF LISTER.

THE publication of the life of a great man should usually be delayed for some years after his death in order to ensure an unbiassed and considered perspective. The interval of five years since Lord Lister's death is not long, but circumstances have been altered in an unprecedented degree by the intervention of the war, which has rapidly dislocated the ordinary limitations of time and set up a permanent barrage between 1913 and the present year. Further, the condition of the wounded has acutely emphasized the importance of the antiseptic as against the aseptic method applicable to civil life, and the search for the most suitable antiseptic agents, so patiently pursued by Lister years ago, is now engaging the attention of many bacteriologists and surgeons. The time for the appearance of this engrossing memoir is therefore fully ripe. Foreseeing that some kind of biography was inevitable, Lord Lister had expressed a wish that it would be confined to an account of his scientific and surgical work; but such a narrow scheme is incompatible with a true biography, which should deal with character as well as with achievements, and Sir RICKMAN GODLEE, feeling that the world has a right to know something of the inner life of one of its greatest benefactors, has described the man as well as the surgical pioneer with discrimination and success.¹

The atmosphere of the Society of Friends in which Lister was born (1827) and brought up has so long faded into the past that the sympathetic account of his home is interesting for this reason, and further is of special value in throwing light on the factors influencing his character and outlook on the world. His wish to be a surgeon was spontaneous in childhood, for none of his family except a distant cousin was a doctor, and at first his father rather discouraged the idea. After school at Tottenham he entered University College in 1844, and spent the next nine years in taking an arts as well as a medical degree, a course which his father advised and Lister himself always recommended to young men when their circumstances made it possible. His rather secluded life there was not very happy, and an attack of small-pox followed by a premature return to enthusiastic work precipitated a severe breakdown with mental depression. Like many other men afterwards distinguished he came much under the influence of Sharpey and was attracted to Wharton Jones, then ophthalmic surgeon, whose experiments on the circulation in the frog's web he subsequently repeated when investigating the early stages of inflammation. After a transient attraction to medicine, possibly the result of his house-physiciancy to W. H. Walshe, one of the most brilliant physicians of the day, he went in 1853 to Edinburgh with an introduction from Sharpey to Syme, who was destined to guide his professional progress during the most critical stages of his life, and to become his father-in-law. He was received with open arms, was given ample opportunities of work, and eventually became house-surgeon in the Royal Infirmary to Syme, then in the zenith of his powers. It is almost impossible to avoid a comparison between these two men who successively led the surgical profession in the northern Athens: Syme arousing strong opposition as well as friendships, and enjoying contests; Lister peace-loving, humble-minded and retiring, though in the future often obliged to defend his principles. Things now began to move rapidly with Lister, for he became an extramural lecturer in 1855, assistant surgeon to the infirmary in 1856, and in the same year married Syme's daughter, who for thirty-seven years devotedly helped and sympathized with his labours and anxieties. His marriage necessitated his retirement from the Society of Friends, but did not entail any break in his family relations, as is shown by the charming letters to

his father and brother interspersed throughout the book. Incessant application to work occupied his six years in Edinburgh, for, in addition to surgery, he carried out investigations on the structure of smooth muscle, the early stages of inflammation, and the coagulation of the blood.

In 1860 he was called to the Regius Professorship of Surgery in Glasgow, but his life continued on much the same lines; two articles contributed about this time to Holmes's *System of Surgery* on amputations and anaesthesia may be mentioned; a high reputation for scientific ability often renders us slow to recognize the value of practical results from the same source, and it must be admitted that Lister's new operations and modifications of surgical technique have been thrown into the shade by his outstanding achievements and so escaped the notice they would have received had he done nothing else. Meanwhile, as the result of constant thought, the germ of the campaign against infection of wounds was gradually developing in his mind, and with the close of 1865 the period of his life during which he was on much the same lines as other surgeons comes to an end. The present generation can hardly conceive what a revolution the antiseptic method induced in the practice of surgery. The graphic chapter on "hospital diseases"—namely, erysipelas, pyaemia, septicaemia, and hospital gangrene—which were so rampant in the middle of the last century that operations were reluctantly performed and mainly confined to the extremities in urgent cases, and hospitals had sometimes to be closed on account of the appalling operation mortality, reads like a nightmare. Pasteur's discoveries on fermentation were applied by Lister to the infection of wounds, and formed the starting point of experiments, observations, and constant modifications of methods involving such an amount of work that the reader is lost in admiration at his perseverance in the face of recurrent disappointment, opposition, and misrepresentation. Comparatively soon, however, his clear grasp of the essential principles and his extreme care in carrying them out gave encouraging results, and for a short time in 1866 he thought of writing a book on the subject; this was never done, and indeed it is difficult to believe that he could have carried it through, for though his papers read clearly and smoothly, he found composition difficult as he painfully weighed the exact meaning of each word and corrected and rechecked the proofs with conscientious anxiety. The very considerable bulk of the collected papers, published to celebrate his eightieth birthday, gives some impression of the self-imposed burden in making his message known to the world. The work entailed in the prevention of wound infection was continued in Edinburgh when he migrated in 1869 to succeed Syme as professor of clinical surgery.

The history of the opposition to antiseptic surgery, though humiliating in the light of the present day, is not surprising, since all great advances pass through various phases of opinion before final acceptance. At first the general attitude was that of apathy, then that of more active measures. The following incident, sketched with Sir Rickman Godlee's characteristic light touch, refers to a representative surgeon of the time: "When full of the confidence of youth, and doing my best to educate my superior officer—no less distinguished a man than Sir John Erichsen—I lamentably failed with a compound fracture, for reasons now easy to recognize, and received from him the stern injunction, 'No more antiseptics.'" A more extreme instance was that of one of the best known London surgeons, who, on hearing of Lister's open operation for wiring the patella, was reported to have delivered himself thus: "Now when this poor fellow dies it is proper that someone should proceed against this man for malpraxis"; the occasion did not arise. In numerous instances the method was given a perfunctory trial, and after the inevitable failure was dismissed as no better than the old and cherished routine. It was, perhaps, because London was so slow to adopt his principles that in 1877 Lister accepted a call to King's College and left his large and enthusiastic following in Edinburgh in order to fulfil his mission. His second period there had been the happiest and probably the most brilliant in his career, and contrasted with the somewhat chilly and depressing reception at King's College, where his classes were so small that for years Sir Watson Cheyne, who accompanied his chief as house-

¹ Lord Lister. By Sir Rickman John Godlee, Bt., K.C.V.O., M.S., F.R.C.S. London: Macmillan and Co. 1917. (Pp. 676; 33 illustrations. 28s.)

surgeon with three others to inaugurate the antiseptic method, attended the classes to add one more. In a very short time, however, the medical societies of London showed their estimation of Lister's worth, homage was poured out abroad, and in time prejudice passed away and the London profession fully accepted the man and his message. In a chapter devoted to an interesting comparison of antiseptic and aseptic surgery Sir Rickman points out how Carrel's recent practice would have delighted Lord Lister, as it is an extension of his fundamental principles. In 1892 the age limit terminated the professorship at King's College, and after another year his wards and private practice were given up. In this latter year the death of Lady Lister left him a lonely childless man, but fortunately his time was fully occupied by the Royal Society, of which he was first foreign secretary and then president, until 1901. Both before and after his retirement from practice honours crowded upon him, the most exceptional being that of a peerage in 1907. But after 1901 the weight of years exacted an increasing penalty, and the last eight years of his life were tedious and overclouded with increasing disabilities, but the arrangement of his collected papers for publication was a source of great interest to him. It was obvious to all those in any way associated with carrying the proposal through that it gave him pleasure, and we now know from Sir Rickman Godlee that it removed a weight from his mind; he had been making arrangements for such a publication after his death, but doubted whether he was altogether justified in imposing so heavy a task on his nephew, the late Dr. A. H. Lister, who was even then not in robust health.

Successful biography depends on two essentials—a fit subject and a proper manner or style in the representation; that Lord Lister is one of the great figures in the history of the healing art there can be no question, and that Sir Rickman Godlee has provided a memoir that will live as one of the great biographies every competent critic must cordially agree.

NOTES ON BOOKS.

Women of the War,² by Mrs. FRANCIS McLAREN, contains thirty-one brightly written personal sketches of women who have taken a prominent part in some field or other of war work. As Mr. Asquith states in an introductory note: "These narratives are as good evidence as could be found of the depth and universality of the appeal which the war has made to our women, not only for sympathy but for service." The author, by choosing the biographical method, succeeds in giving a more vivid story than a merely general description would convey. If her selection and arrangement of subjects seem at times capricious, this is a minor blemish in a work which makes no pretence at exhaustive treatment. Her sketches will bring home to the casual reader something of the industry, bravery, and versatility shown by women in countless directions, notably in hospitals, munition works, canteens, and hostels, in the supply of medical comforts and equipment, in work on the land, and in driving motor cars, and other auxiliary services of the army. In the opening chapter on the pioneer work of Dr. Garrett Anderson and Dr. Flora Murray, who organized the first hospital unit staffed by women, the author states quite justly that the success of this enterprise has greatly advanced the position of women in the medical world. The volume is freely illustrated with portraits, and the frontispiece is a charming example of the art of Edmund Dulac. A fuller account of women's work in munition factories is given by Miss FOXWELL in a little book called *Munition Lassies*,³ founded on the experience of six months as principal overlocker in the danger buildings of the Woolwich Arsenal. Many people will be glad to gain an insight into the life of the woman munition worker through the medium of these bright and gossipy pages.

When we take up a book with the title *Adolescence*,⁴ by STEPHEN PAGET, we know that we shall find a difficult subject handled, delicately indeed, but courageously. It is courage that in real life most of us lack. Mr. Paget

advises a solemn talk between father and son, or mother and daughter, at some suitable age; the difficulty of choosing the age aright has perhaps influenced him in preferring parent to school teacher. However this may be, and whether the heads of the talk Mr. Paget suggests will be the best for all children, many parents will be grateful for the middle part of the book, which turns on that wise saying, "The reasonable soul and flesh is one man." His comment is, "it follows that what we call temptation addresses itself not to the flesh alone, but also to the reasonable soul," and he has the courage to go on to praise early marriages. The book is very short, no more than a brief lecture to Oxford University extension students. But this is one of its merits; it is just enough to set a father or mother thinking, as we believe, along right lines. It is to be hoped that Mr. Paget will resist any temptation to make another edition longer.

Captain PRICE-JONES'S *Blood Pictures*⁵ is a brief but well written introduction to the clinical study of the blood. It begins with an account of the technique of haemacytology and the normal blood picture. Then follows an account of the use of blood counts in the diagnosis of disease that is short but most serviceable. There are five coloured plates of blood corpuscles, which are well reproduced. The book should be in the hands of all medical students, and will be found useful by many of their seniors, too.

⁵ *Blood Pictures: An Introduction to Clinical Haematology*. By Cecil Price-Jones, M.B. Lond., Captain R.A.M.C. (T.C.). Bristol: John Wright and Sons, Ltd. 1917. (Demy 8vo, pp. 91; 5 coloured plates, 4 figures. 6s. 6d. net.)

HEALTH PROBLEMS AND RECONSTRUCTION.

ADDRESS BY THE MINISTER OF RECONSTRUCTION.

A MEETING under the auspices of the Faculty of Insurance was held at the Central Hall, Westminster, on November 24th to hear an address by Dr. Christopher Addison, M.P., Minister of Reconstruction. The chair was taken by Mr. H. KINGSLEY WOOD, Chairman of the London Insurance Committee, who, in some introductory remarks, said that if the national health problem were solved, the master key to reconstruction was found. It was useless to erect an educational ladder for the child if the child had not the physical stamina to climb it. Since the outbreak of hostilities a quarter of a million children had died whose lives might have been saved, and no fewer than a million weak and defective children were now in the schools. Some four million parents and children were living in slum areas. The health conditions of the country were an urgent war problem.

DR. ADDISON'S ADDRESS.

Dr. ADDISON, after expressing his indebtedness to the Faculty of Insurance for the practical and accommodating spirit in which they had approached this question, said that Mr. Bonar Law, in answer to a question in the House of Commons, had said: "Steps are being taken which it is hoped may secure substantial agreement amongst those who are actively engaged in the work of national health." It fell to his (Dr. Addison's) lot, as Minister of Reconstruction, to do what he could to arrive at an arrangement which would be workable, comprehensive, and practicable, and to bring into it as far as possible by agreement the various parties concerned. The question was complex and must be approached in a courageous spirit. He warned them against taking hold of phrases such as "A Ministry of Health" without having clearly in their minds why they wanted it and what they wanted it to do. Too many people were satisfied with phrases, and what was required more than anything else in health matters was reality. At present fourteen Government departments and 1,800 local authorities were more or less concerned with health administration.

Tuberculosis.

It did not necessarily follow from this multiplicity that the system was inefficient, but the way in which it worked out could be seen if he took as an illustration the case of a man coming out of the army. Should this ex-soldier be tuberculous, quite a number of departments were concerned with him and his household. The Ministry of Pensions would desire to get him into a sanatorium, which was provided by the Local Government Board after consultation with the Treasury. But before the Treasury gave its

² *Women of the War*. By Barbara McLaren. With an introduction by the Right Hon. H. H. Asquith, M.P. London, New York, and Toronto: Hodder and Stoughton. 1917. (Demy 8vo, pp. 160; illustrated. 3s. 6d.)

³ *Munition Lassies*. By A. K. Foxwell, M.A., D.Litt. London, New York, and Toronto: Hodder and Stoughton. 1917. (Cr. 8vo, pp. 156; illustrated. 1s. 3d.)

⁴ *Adolescence*. By Stephen Paget. London: Constable and Co., Ltd. 1917. (Pp. 59. 7d. net.)

consent it would have to consult the Insurance Commission, and when these three departments had settled the question as to the necessity of the sanatorium, the institution would be administered by the local authority. Further difficulties arose if and when the man was discharged from the sanatorium as an advanced case. It had sometimes happened that men had to be accommodated in hospitals which were formerly—or were still to some extent—under the Poor Law.

Then the man's family and its liability to infection from him came into the question. In many places—but not by any means covering the country—there was an organization by which those who were brought into contact with people affected with this disease could be examined at the local dispensary or clinic. If the consumptive's child attended school it would be examined by the school medical officer, who was responsible to the Board of Education. After school age, the youth was looked after by the Home Office, so far as concerned the health conditions of his place of employment. All these authorities and others—including the local health authority in its supervision of the sanitation of the home, and the Board of Agriculture, in which was vested the responsibility for the supply of good milk for the child—were concerned in a simple and common case of that kind.

Maternity.

As a second illustration he took maternity. Mr. Kingsley Wood had said that a quarter of a million children whose lives might have been saved had died since the war began, and even this left out of account the loss of prenatal life, owing to the conditions of employment of the mother and other circumstances. Schools for mothers were in existence, partly under the Board of Education and partly under the Local Government Board, but he was glad to say that a very satisfactory working arrangement between those two departments was now in sight and the division of functions was quite rationally and properly defined. Another authority came in with the need for proper attendance on the woman at the time of confinement—namely, the Privy Council, which was concerned with the organization and control of midwives. Then the insurance society to which the woman belonged, if she was a worker, was interested in seeing that she was properly cared for. Apart from all the organizations he had mentioned, there still remained the Poor Law authority, which had done a great deal to provide for the necessities both of maternity cases and of the sick poor. But the Poor Law organization had no relation either to the insurance organization or to the local health authority.

Need for a Central Department for Inquiry and Supervision.

Health was a complex matter; food, and habits of life, and hours of work, and many other factors, were concerned. Unhappily, there was no body of men whose business it was to consider all these matters—now under the control of many different departments—and to formulate a policy and advise the Government. At the Ministry of Munitions under Mr. Lloyd George there was set up a Health of Munition Workers Committee, who had studied all these various aspects of the question as they affected munition workers, and one of many results of a precise investigation was that a relation had been discovered between hours of labour and working efficiency. In the case of women engaged in turning aluminium fuse boxes, whose hourly output at 66 hours a week had been taken as 100, it was found that the output rose to 134 when the hours were brought down to 54.8, and to 158 when the hours were again reduced to 45.6. In the case of boys on light work, 100 again being taken as the hourly output for a 72-hour week, the figure became 117 for a 54-hour week, and 129 for a 53-hour week. Among men engaged on heavy work, with 100 as the standard for a 58-hour week, the output rose to 139 for a 51-hour week. Up to the present it had been no one's business in particular to find out such things so far as they related to the general community, and in after-war conditions, when it would be vital to increase the productive powers of the nation, there must be some body whose work it would be to collect all information bearing on the health of the people, and to discover where the gaps were and how they might be filled. They must not blindly embark upon policies. He

was at present trying, for instance, to get some precise information as to the effect of good physical training on young people between the ages of 14 and 18, and the answer to the question whether and to what extent such training should be given was one to be based, not on guesswork, but on properly acquired data.

The new central health authority, when it was set up, would obviously be concerned in the first place with matters relating to disease, its origin and treatment, but this could not be handled by an authority unless it had powers to deal with matters affecting sanitation. The proper housing of the people was one of the most important elements in a health system. Then there had to be considered all the functions—great and growing ones—which attached to insurance committees as affecting health, and also those of that other great branch of the health service—namely, the Poor Law administration. The popular objection to associating health administration with the Poor Law arose quite rightly from a recognition of the fact that health was something quite different from destitution; they were not entitled to label ill health as poverty. But for all that it was evident that the Poor Law health service must be taken into consideration. A good hospital could not be scrapped because hitherto it had been called a Poor Law hospital.

Local Administration.

Any proper system of health administration must depend on a good working arrangement between the publicly elected bodies and the insurance committees. While the first thing to aim at was to get the general plan right and the central executive department constituted on right lines, he did not anticipate that anybody, after the experience of war control, would want everything to be done by a department in Whitehall. They must look forward to a considerable measure of decentralization of control, otherwise the central department would be greatly over-weighted, too congested with ordinary routine business, and too far removed from the realities of a locality to work efficiently. The first thing to which the central department would have to address itself would be the working out of a proper health plan and policy, and the necessity of the situation at the moment was to get the body created whose business it would be to take this in hand. Parliament had no time now to carry through a highly controversial measure, and therefore if progress was to be made, a sufficient amount of agreement in advance must be forthcoming with regard to the setting up of this central authority. It was not a fact that departments and authorities were fighting one another, but simply that each department was keenly absorbed in its own work and had no time for the difficulties and tasks of others. It had been his business as Minister of Reconstruction to try to work with different Government departments, and he found that when a big national question was put before them, departmental rivalries bulked nothing like so largely as people supposed.

This matter would not wait. With the end of the war a burden of quite unprecedented character would be thrown upon health authorities, not only in respect to demobilized soldiers, but to civilians in the reaction after war tension. The machinery ought to be ready and competent to deal with the problem, otherwise the whole subject would be lost in the babel of counsels. Three great branches of work in particular ought to be arranged before the emergency arose—namely, the whole question of hospital organization, the whole question of nursing and midwifery provision, and—a most thorny one—the whole question of the relation of State health administration to the medical profession. He knew that the British Medical Association strongly took the view that it was the first necessity to create a central organization which would think out and consider the subject in advance. He confidently appealed for the sinking of minor differences and for the question to be regarded as a whole from the point of view of the national interests.

DISCUSSION.

At the close of Dr. Addison's address brief remarks were made by Mr. W. S. BENNETT (National Conference of Friendly Societies), Mrs. OGLVIE GORDON (National Union of Women Workers), Mr. A. W. YEO, M.P., Mr. P. ROCKLIFF (National Insurance Joint Committee), Mr. E. PORTS (Association of Insurance Committees), Dr. ALFRED COX (British

Medical Association), and Sir ROBERT MORANT, who, as a civil servant addressing a public meeting, asked that he might not be reported.

Dr. Cox said that Dr. Addison had given proof that he was behind the efforts which were being made in public and private to bring about an agreed bill, and the British Medical Association had shown that it was prepared to do what it could to further such an agreement. Quite thirty years ago the Association arrived at the opinion that there ought to be a unified body to deal with health matters. Since the advent of national insurance many of those in that room had come into contact with the medical profession over quite sordid questions of remuneration, and this had upset the relations which might have existed between the organized medical profession and other bodies. Such a process was inevitable until the economic conditions governing medical service were satisfactorily settled, but he hoped that the new spirit which would permeate the Ministry of Health would make all such unprofitable bickering a thing of the past. The only stipulation, to be made from the very beginning, was that the medical profession must be consulted, for it was not right to fix the future terms of medical employment without first asking the approval of those most concerned.

Dr. ADDISON, in reply to a vote of thanks, said that the thing which had impressed him was that he had seen in that room, for the first time on an unanimous errand, the representatives of great organizations, medical, locally and centrally administrative, Government departments, and other authorities, and he thought it betokened a willingness on the part of all to try and work in a patriotic and wise-minded manner towards their common objective. He hoped people would realize more fully that the war was going to sweep many old things away, and that they would need all their resolution and good sense to face the difficulties ahead.

THE SANATORIUM TREATMENT OF TUBERCULOSIS.

ANNUAL REPORTS.

Lancashire County Council.

THE Central Tuberculosis Officer for Lancashire has issued a very full statistical report of the work done by the twenty-two dispensaries and by the pulmonary hospitals and sanatoriums at present available throughout the county. The actual accommodation projected for such institutional treatment has had to be greatly curtailed owing to the war.

A large number of cases have been dealt with, and in so far as the early cases are concerned, with a good percentage of success. From 78 to 80 per cent. of these have been enabled to return to work or were fit for work. In the later stages of the disease the relative amount of success has been progressively smaller. It has to be noted, however, that the death-rate shows a definite increase. This may be due in part to more careful diagnosis. Many cases formerly returned as due to pulmonary disease are now more correctly attributed to tuberculosis, but the fact remains that a very large proportion of these deaths have occurred within three months of notification, and an almost equal number without notification at all. This neglect of notification would appear to be increasing, and hence any statistics founded on notified figures in any district must be more or less misleading. Whether it be due to the unwillingness of patients to allow themselves to be branded as infectious, or to carelessness on the part of the local practitioner, or to mistaken diagnosis, there is an evident need for greater strictness on the part of local authorities if the full value of the system is to be obtained.

The treatment of discharged soldiers and sailors suffering from tuberculosis has not been attended with great success, owing to the difficulty of enforcing discipline apart from military control.

Dispensary and domiciliary treatment has proved satisfactory in many cases and progress has been made in bringing home to consumptives of the poorer class the advantages to be gained by the intelligent use of fresh air. In a few cases, where the environment has permitted of it, shelters have been lent to those willing to make use of them, and good results have been observed.

After-care committees have been able to keep an eye on many of those patients who have returned to work locally, but they have met with the difficulty that has so often hampered their efforts, that sick pay is stopped as soon as work is commenced. At the very time when such extra money is most needed the supply is cut off. This system, it is universally recognized, calls for drastic alteration. Co-operation between the tuberculosis officers and the benefit societies ought to be able to overcome such an obvious defect.

In Lancashire, as elsewhere, the question of the supply of extra nourishment as a part of treatment has had to be seriously discussed, with the result that in many cases it was reduced. A maximum of 4s. a week for milk and cream has now been established. Separate reports from the assistant tuberculosis officers in charge of the areas into which the county has been divided contain many interesting practical points, and the report as a whole deserves careful attention, embodying as it does a very full account of the work done and of the methods employed in doing it.

City of York.

In his annual report the tuberculosis officer for the city of York comments upon the greater prevalence of tuberculous adenitis amongst children during the past year, and indicates very clearly that opportunities for infection within the household are only too numerous. If it be not possible to remove the infecting agent, it is plainly necessary that the susceptible members of a crowded family should be protected in some other way. Open-air schools and separate sleeping accommodation can do a good deal in this direction, and the efforts of after-care committees can be concentrated upon the control within the home of the advanced case. A Tuberculosis Crusade Committee undertakes supervisory work in York and is able to record a creditable account of assistance given where it was most needed, by enabling patients to take full advantage of the treatment prescribed for each case. Friendly visiting and advice, provision of means for temporary isolation and for greater comfort within the home, the loan of shelters for open-air sleeping, and assistance in obtaining admission to seaside homes, or to suitable light employment, have all been forthcoming, and have yielded satisfactory results.

Special stress has rightly been laid upon the importance of dental treatment. Defective teeth and oral sepsis have over and over again been found to be militating against complete digestion and well-being. In dealing with a disease where the proper assimilation of food is all-important, the neglect of dental hygiene is unpardonable. Especially is this the case with respect to the military patients, and vigorous efforts are now being made to remedy the evil.

The want of accommodation for satisfactory institutional treatment is felt as acutely in York as elsewhere, but it is evident that a vast amount of useful work can be done without it. The disease is bred in the home, and it is in the home that its effects must be watched and counteracted. The early case may be arrested by timely sanatorium guidance, but the established and advanced cases can only be alleviated by medical treatment, which can be applied equally well within the home provided that it be controlled by intelligent supervision. The dangers of contact can be greatly lessened by the provision of separate sleeping accommodation and by removal of susceptible inmates to school or other occupation during the daytime.

ACCORDING to the *Annuario Statistico* for 1915 the number of cases of suicide in Italy increased steadily from 2,880 in 1910 to 3,187 in 1914, representing respectively rates of 84 and 89 per million inhabitants. The percentage of women was 24 in 1910 and 28 in 1914. The figures show that in the period of forty years from 1877 to 1914 the proportion of suicides had more than doubled.

STATISTICS published by the United States Public Health Service show a very high proportion of cases of poor eyesight, bad teeth, flat-feet, insufficient weight, and other defects among the men drafted for the American army. There are from 7 to 20 per cent. more young men with defects or in other ways needing medical attention in country districts than in towns. This is believed to be due to the fact that the health of school children is almost entirely neglected in rural districts.

British Medical Journal.

SATURDAY, DECEMBER 1st, 1917.

MEDICINE IN THE REIGN OF GEORGE III.

DR. ARNOLD CHAPLIN has won for himself a special place among medical historians. His researches on Napoleon entitle him to be regarded as the leading authority on the dark days when the sun of the mighty conqueror was sinking into the valley of the shadow of death at St. Helena. He has now embodied in his first course of FitzPatrick Lectures some of the results of the attention he has given to the state of medicine in England in the sixty years from 1760 to 1820 when George III was king. The eighteenth century is often regarded as a very reign of dullness, when learning was largely mere pedantry, literature lifeless artificiality, and religion cold formalism. Yet to some it makes a strong appeal by the polish of its manners at one end of the social scale and the frank naturalism of its life at the other, as portrayed by the pens of Fielding and Smollett and the pencil of Hogarth. The truth is that in the history of human development it was a time of intellectual revolution, when the shackles which for ages had held the human mind in bondage were finally broken. Traditional dogmas were everywhere being called in question, and in science the figments of fancy which had so long passed for knowledge were beginning to fade away under the test of direct appeal to fact. Medicine shared in the general upheaval, but the theorizing spirit which had for ages held sway in that sphere did not readily give way to the experimental method. The mental outlook of the profession in the early part of the eighteenth century is not unfairly represented in the account of the dispute of the Strassburg doctors in *Tristram Shandy* where one side argues that a man in a certain condition *must* spit blood and go off in a consumption, and the other side replies that "it happens otherwise," to be met with the crushing retort "It ought not!" The whole of the old *a priori* medicine is in that contention. It was the natural outcome of an intellectual discipline which taught men to look at things through the spectacles of authority rather than with their own eyes. The great majority of doctors were still of the type of Thomas Diafoirus, who though *fort comme un Turc sur les principes* was in his practice hidebound by traditional rules. In the words of a French satire, they "spat Greek and Latin," and thought, as Kant said, that by giving a name to a disease they had done their duty by their patient.

When George III came to the throne the medical profession was divided into three distinct parts, which were orders of a professional hierarchy consisting of physicians, surgeons, and apothecaries. These classes differed widely in their intellectual equipment, as in their rank in society. The physicians retained much of the tradition of high literary culture which had distinguished them in the earlier part of the century when John Arbuthnot could more than hold his own among the wits of Queen Anne, that brilliant group which included Swift, Pope, and other leaders in thought and letters. Johnson thought him the first man among them, "the most universal genius, being an excellent physician, a man of deep learning, and a

man of much humour." Garth, who by his *Dispersary* won for himself a considerable reputation as a poet, wrote the epilogue to Addison's *Cato*. Among the contributors to the second volume of Addison's *Musae Anglicanae* was Sir Edward Hannes, predecessor of Arbuthnot as physician to Queen Anne, who is described by W. J. Courthope as "one of the many scholarly physicians of the period." John Douglas, whose "soft obstetric hand" is celebrated by Pope, was a man of great learning and formed a unique collection of all the editions of Horace with the commentaries and translations. His successor, William Hunter, made a magnificent collection of works of art, manuscripts, and books; he numbered all the leading men of his day among his friends. Johnson corresponded with his physician, Lawrence, in Latin, and Brocklesby capped quotations with the great moralist on his death-bed. William Heberden wrote his *Commentaries* in classical Latin.

The academic training of the doctor in the time of George III was sound and extensive, but in medicine it was very inadequate, being particularly deficient on the practical side. It is not easy to give a clear notion of what was required of the student of medicine at Oxford and Cambridge, but Dr. Chaplin has taken great pains to get at the facts. The course was long and arduous, and a degree in medicine represented a standard of general culture very much higher than that of the surgeons and apothecaries. But men had to go abroad in search of the practical instruction they could not find at home, and many got their medical degrees at Leyden, Padua, Montpellier, Rheims, and elsewhere.

The account which Dr. Chaplin gives of the long contest between the Fellows and the Licentiates of the College of Physicians is a curious example of the growth of a privilege and of the tenacity with which men will fight for it long after it has been shown to be ill-founded, and of little or no value to the holder. In this instance the first step was taken within forty years of the foundation of the College, when it decided to limit the number of its Fellows, and instituted a grade of Licentiates, who also were physicians. Outside the walls of the College a Licentiate enjoyed the same privileges and distinction as a Fellow. Next the practice grew up of limiting the Fellowship to M.D.'s of Oxford or Cambridge, and for the retention of this shadowy privilege graduates of those universities fought hard for over a century in the law courts and finally before a Parliamentary Committee. It was not until after this committee had reported, in 1834, that the by-law limiting the Fellowship to graduates of Oxford and Cambridge, which the courts had nearly forty years before declared to be bad, was amended. The practical effect of the closing of the doors of the College against all but men from the older universities, whose medical education had often been little better than a farce, was the exclusion of some of the most progressive spirits among the physicians of the day, including William Wells, of whose scientific investigations, carried on under great difficulties in a race against death, Dr. Chaplin gives a moving account.

The character of the physicians in the eighteenth century stood high; as to this we have Johnson's testimony when he says that "every man has found in physicians great liberality and dignity of sentiment, very prompt effusions of benevolence, and willingness to exert a lucrative art where there is no hope of lucre." These social virtues found their due reward, not only in the esteem of the best men of the day, but also in money, for Dr. Chaplin has come to the

conclusion that a relatively larger number of physicians gained a handsome competence from their practice in the reign of George III than is the case at the present day.

The apothecaries were the general practitioners of the day, and fine ladies spoke of "using the 'poticary'" when they meant calling in the doctor, a form of speech which continued till far on in the nineteenth century. Among the apothecaries the standard of general education was low and their medical knowledge was largely made up of traditional superstitions, while their treatment of disease consisted in the routine administration of drugs of the properties of which they had no scientific knowledge. They were, in the words of Pope, "bold in the practice of mistaken rules." The commercial part of pharmacy was, however, well understood; hence *purgare* and *clysterium donare* were the cardinal rules of practice. The business of an apothecary was in the truest sense a trade, which was learnt, like other trades, by an apprenticeship. But it is only fair to state that the Apothecaries' Society, by its fine Physick Garden presented by Sir Hans Sloane and at a later date by the institution of lectures on materia medica, did much for the promotion of scientific pharmacy. The teaching of anatomy was a matter of private enterprise. When William Hunter offered to contribute £7,000 towards the foundation of a central school the offer was rejected. Surgery was also taught by private lecturers. A number of lying-in institutions were formed which offered opportunities for the practical instruction of students, and doctors who conducted such institutions took private pupils.

There was no central authority empowered to regulate medical education or the practice of the art. The College of Physicians, the Corporation of Surgeons, and the Society of Apothecaries respectively exercised some sort of jurisdiction over their own subjects. But their powers were limited, and, such as they were, they were often not strictly enforced. The College of Physicians, by its original charter granted by Henry VIII, had authority over all physicians in London and within an area of seven miles around, and could grant licences to all physicians in England; but it had no control over graduates of Oxford and Cambridge practising in the provinces. In 1775 we find Johnson in his opinion, inspired by Lawrence, on the case of the Aberdonian Memis, who objected to be called doctor rather than physician, writing that "in England whoever practises physic not being a doctor must practise by a licence; but the doctorate conveys a licence by itself."

The Corporation of Surgeons and the Society of Apothecaries each exercised jurisdiction over its own members, but the control was less effective than that of the College of Physicians, particularly in the provinces. To this lack of jurisdiction was due the fact that unqualified practitioners were in a large majority. The country surgeon, in fact, seems to have looked upon the obtaining of a diploma as an act of grace and professional expediency rather than of legal necessity. Towards the end of the eighteenth century these "buccaneers of the profession," as Dr. Chaplin calls them, became so numerous that it was felt the time had come for sweeping away a crying abuse. The results of the efforts of some enlightened reformers was the passage of the Apothecaries Act in 1815. That Act, which was the forerunner of all subsequent medical legislation, was the first formal expression given in this country to the principle that all who practise medicine must be legally qualified. But, though it constituted an immense advance by enforcing

examination on all who wished to practise the art of healing, there was still much need for reform in medical education. To say nothing of the narrowness and general inadequacy of the curriculum, the London hospitals were close boroughs, and the privilege of "walking" them was more a shadow than a reality. There was no clinical teaching except for the private pupils of the surgeons, and the resident appointments were reserved for the few who could pay handsomely for them. Thomas Wakley set himself resolutely to let daylight into the dark places of hospital management by a campaign which it required no small courage to undertake, for he had all the powers and dominations of the profession arrayed against him. He conquered, but only after a fierce struggle. The end of the old reign of privilege and favouritism came when the newly founded University College Hospital threw open its appointments to competition. That reform was nothing less than a revolution. It was the fulfilment in the republic of medicine of the Napoleonic maxim, *la carrière ouverte aux talents*.

Dr. Chaplin has interpreted his title very strictly, carefully eschewing any reference to surgeons. We could hope that the College of Surgeons, after he has completed by his course next year his account of the physicians, would ask him to render a similar service to the surgeons. Though the art of the surgeons in the reign of George III was rude and limited by ignorance of morbid processes and the methods of preventing sepsis, and by the lack of anaesthetics, they were brought into more direct contact with facts than the physicians. This made them less visionary and more practical than the more learned practitioners at whom Abernethy was never tired of gibing as "the doctors," and these qualities must have had an effect upon the physicians with whom they came into relation. Moreover, any account of the progress of the study of morbid anatomy in the period must be imperfect which takes no account of the work of John Hunter, who possessed that touch of genius which, while it rouses opposition in some, exercises a profound influence over the more active minds of a generation.

FOOD PROBLEMS.

In our issue of November 17th we briefly alluded to the revised edition of Dr. Leonard Hill's memorandum on the feeding of munition workers. We propose now to refer to certain problems suggested by the new data published by Dr. Hill.¹

The memorandum contains a table (p. 11) of the quantities of food received by munition workers in fifteen hostels and canteens. If we exclude three of these, those lettered E, J, and O, in which Dr. Hill states the diet to have been insufficient, and reduce throughout to "man values," we find that the daily consumption per man was approximately 121 grams protein, 143 grams fat, and 411 grams carbohydrate—yielding 3,511 calories. Similarly the average weekly consumption per man of bread was 5½ lb.; but the individual figures are irregular, several hostels showing a consumption of more than 6 lb., the average being affected by one or two in which the amount taken was extremely small. The actual quantities of meat consumed are not stated, but it may be concluded from the absolutely high fat and relatively high protein values that they were above the level of ordinary working-class populations. By analysing the data of working-class budgets published by the Board of Trade which relate to conditions obtaining

some years before the war,² we find that the man value in calories varied from 3,094 in families earning less than 25s. weekly to 4,013 in those receiving upwards of 40s., while the amount of bread and flour never fell below 7 lb. 5 oz., and that of meat never exceeded 2 lb. 6 oz. The percentage of total energy derived from cereals was over 50 in all the Board of Trade's families, while it only reached this level in one of Dr. Hill's series, and was below 40 in more than half the observations. It is therefore obvious that the munition workers in the spring and summer of this year were receiving a far larger proportion of their energy from animal food than has been usual among the hand-working classes of this country.

There are no doubt certain advantages in this. Major McCay in his valuable treatise on *The Protein Element in Nutrition*³ pointed out, as a statistical fact, that the fighting and working races of all parts of the world, including India and Japan, do habitually consume large quantities of animal protein; it is certainly arguable that the specific dynamic energy of protein in metabolism is normally an important factor of high-pressure working capacity, and that this *luxus* consumption (a *luxus* consumption from the point of view of minimum protein requirements, which, as Rubner showed, might be reduced to as low a figure as 25 to 35 grams for a 70 kilo man) has played a part in the enormous production of munitions of war in our factories. On the other hand, certain difficulties are created. High protein feeders, and in ordinary practice this means large consumers of meat, will necessarily suffer more from a curtailment of their rations than those accustomed to derive a large proportion of their energy requirements from carbohydrates. The high protein feeder is in effect maintaining a larger cellular mass, the requirements of which will immediately become irksome when the ration is reduced, always supposing that he is in active muscular work and does not possess considerable accumulations of *dépôt* fat.

A secondary consequence is that German docility under privations may be an unsafe guide for us. It would appear from Loewy's data⁴ that the Germans have for some time, probably from the very commencement of the war, subsisted upon a diet extremely rich in carbohydrate and poor in animal protein; our own working classes, on the other hand, have, down to a recent date, been directly and indirectly encouraged to consume animal in preference to vegetable food. Consequently a reduction of meat consumption to a level somewhat below that of all but the very poorest families before the war and to far below the standard of Dr. Hill's representative sample of munition workers, is a much more considerable change than appears on the surface. That even the proposed meat ration is much greater than the amount consumed by German civilians for years past, is a proposition at once true and irrelevant.

We state these considerations, not as implying any censure upon the proposed ration which Lord Rhondda has stated to have been approved by scientific men (doubtless the Food Committee of the Royal Society), but in order to dispel the impression that what is demanded will be an easy sacrifice for people who are working hard; for the sedentary there should be no great difficulty. But for manual workers it is a change of some gravity, the more so as the rationing of bread and cereals does not permit of a return even to the pre-war working-class standard,

but necessitates the large utilization of potatoes. To make this point plain, we recur to the analysis of the voluntary ration published in our issue of November 17th. For men on medium work the ration provides just under 2,100 calories, and on the Atwater standard basis (practically endorsed by the Royal Society) some 3,500 calories are required, so there is a deficit of 1,400 calories. The only unrationed articles of high energy value are fish, dried pulses, and potatoes, for cheese and milk are specified as not being generally available, although the official utterance on this point is, as we remarked, vague.

Dr. Hill's memorandum gives no data respecting the consumption of fish, but, from inquiries we have made, we conclude that a weekly consumption of 0.6 lb. is unlikely to be exceeded in industrial centres. On similar grounds, we think that a daily consumption of one pint of milk is the utmost that can be reached. These two additions would provide about 457 calories daily, leaving 943 to be obtained from potatoes; we are assured the available quantities of dried pulses are too insignificant to enter seriously into the reckoning. Taking the energy value of potatoes to be 427 calories to the pound, this means a daily consumption of 2.21 lb., or a weekly supply of just over 7 kilograms.

According to the report of the Royal Society's Food Committee⁵ the total weekly supply of home grown and imported cereals (1909-13 average) works out to 93,557.7 metric tons. Taking the Committee's estimated man value for the 1916 civilian population, the cereal quota is 2,613.3 metric tons per million "men." The value reached above for covering the energy deficit of the ration with potatoes requires a weekly supply of seven thousand metric tons per million men; this is more than two and a half times the whole supply of cereals normally available. It is obvious that the effective substitution of potatoes raises transport problems of great magnitude and complexity, and the figures emphasize the wisdom of the Wheat Commission's policy, epitomized by Dr. Hill, which is to make the widest use of all energy-producing substances capable of milling in the production of flour. The transport of cereals and their derivatives has long been highly organized, while that of potatoes upon so large a scale has never been attempted, although the need for an experienced and expert organization is actually greater. Official advice to the public to make free use of the unrationed potatoes will not produce the desired effect unless the method of distribution is more efficient than it has so far been.

The medical profession has it in its power to render important service at the present juncture, although, so far as we are aware, the Food Ministry has not made any attempt to obtain the collective advice and aid of the profession as a whole. In the first place, medical practitioners can further the policy of the Wheat Commission by discountenancing the complaints, in the vast majority of cases quite frivolous complaints, made against war bread as a source of digestive troubles. In the second place, those practising in districts, such as the outer suburbs of London, where large crops of potatoes are locally available, will be fully justified as scientific men in urging the inhabitants to make the fullest use of them. It should be pointed out that the utilization of the protein of potatoes by the body is singularly good. Rubner,⁶ for instance, has shown that it is possible to bring a man into

nitrogenous equilibrium with less than half the intake of protein requisite upon a bread diet when potatoes formed the source of supply. Assurances should be given that the increased bulk of the faeces upon such a diet does not in the slightest degree prejudice health.

A not less important duty of the medical profession is the instruction of the public in the fundamental principles of nutrition. Our experience is—an experience confirmed by almost every issue of the daily press—that few members even of the educated public really grasp the fact that the law of conservation of energy applies as stringently to the human body as to any other machine. Such persons do not comprehend the relation between mechanical output and energy intake, and seem to suppose (as did the late Food Controller) that “calories” are a scientific fad of the “doctors” without importance to the practical man. The sedentary office worker and the society or suburban lady should be taught why the hand-working classes need large quantities of food, and dissuaded from attributing the growth of consumption of foods in these days of strenuous labour to the reckless and improvident habits of the working classes receiving high wages.

If the view we take of the situation is just, ill informed statements of the kind mentioned are peculiarly liable to precipitate a crisis, and the efforts of the medical profession, the only class of the community which can claim to speak with authority upon these matters, should be put forth.

THE PROBLEM OF THE DISABLED SOLDIER.

THE Ministry of Pensions is engaged in a fresh effort to persuade disabled soldiers to be rebuilt and to be trained to greater efficiency, in their own interest and that of the nation. Were it not for the importance of the matter this endeavour to study the psychology of the disabled soldier would have a humorous aspect. Oliver Wendell Holmes long ago remarked on the suspicion men have of anything which is freely offered to them, and in the present instance the sense of regained liberty—so very sweet despite its handicaps—probably gives rise to further hesitation. Some of the men apparently fear that if they are cured and their earning capacity thereby increased their pensions will be cut down. That is not so. Others are concerned to take up the immediate opportunities for work. A few may even have a prejudice against the medical profession, and a distrust of modern science, or, as they would call it, of “new-fangled notions.” Before they became well-set-up quickly moving soldiers of the King, many of them lived within village environment, and knew little or nothing of “book-learning.” In the mind of such men the word “orthopaedic” awakens vague apprehensions; to refer to them as “neurasthenic” seems a term of opprobrium, or as they would say, “calling them names”; and they have not the smallest inclination to go into sanatoriums. In these circumstances it is recognized that the ordinary notices published in departmental style are inadequate, and little books are being issued by the Minister of Pensions to tell disabled sailors and soldiers how fatherly his office really is. These booklets are all the better because, without any condescension or patronage, they are yet written in simple and popular language with due regard to the audience addressed—a consideration too often neglected in Government productions. Some facts cannot be too often repeated. The first is that the pension given on discharge is permanent; hence there will be no reduction while a man is under cure or treatment, nor, as has already been said, will the fixed pension be affected by increased earning capacity derived from the cure. The second is that if this fixed pension be not on the highest scale, it will for the period of treatment be put on that scale. A private

soldier will get at least 27s. 6d. (non-commissioned officers and warrant officers more—up to 42s. 6d.), and he will not have to pay more than a shilling a day towards his maintenance if he has to live in an institution. If, while being cured, he lives away from home he has allowances for wife and children. If his cure goes on while he lives at home he has allowances for the children. The story of the methods of cure reads like a modern romance, and yet we know it to be true. Incidentally it shows how the medical profession has risen to the great occasion of the war and how rapidly fresh extensions of this national service are proceeding. And, indeed, the value of the treatment has only to be properly known to be appreciated.

THE MEDICAL RESEARCH COMMITTEE.

THE third annual report¹ of the Medical Research Committee, dealing with the year ending September 30th. 1917, has been presented to Parliament. The report begins by pointing out that though, as a matter of convenience for purposes of reference and historical continuity, schemes of inquiry are set out in two groups—those initiated before peace was broken, and those framed to meet the special needs and opportunities for research that have arisen from the conditions of war—the distinction has in practice become insignificant. The report calls attention again to the value, in permanence, which may spring from the study of problems emerging, as in war time, from unusual and temporary conditions. The occasions of war have called imperatively for inquiries into the proper treatment of wounds and of their various infections, into the control of epidemics like those of cerebro-spinal fever, into the physiological meaning of surgical shock and collapse, into the nature and treatment of functional nervous disorders, and, indeed, into almost every corner of the whole field of medical science and practice, whether for Europe or the tropics, and into every branch of surgical manipulation and contrivance. Further, the disturbance of civil life has offered other problems of equal urgency in the medical sphere, due to the stress of industrial work and the unfamiliar limitations in food supply. The conditions of war have provided not only insistent demands for the application of scientific method, but many exceptional opportunities for its easy and fruitful use. As an example, reference is made to a section of the report which deals with the study of the kidney efficiency of no fewer than fifty thousand young men considered to be in good normal health, and leading active lives in a training camp. This survey had immediate importance as part of an inquiry into the kidney deficiency found to result from life in the trenches in a small percentage of men, but at the same time it has given new information upon a scale never obtained before, or easily obtainable with regard to the health of the young male population of the country. Another point made in the introductory passages of the report is that the conditions under which patients are admitted to the great civil hospitals have caused medical investigations in them in peace to be directed commonly to the study of disease in its advanced stages rather than to the detection and study of the early stages, which, if a patient is aware of their existence at all, he accepts for the time as private or unimportant. Owing to the fact that to the medical services of the armed forces and in the medical supervision of workers at home prevention is more important than cure, the bias of effort is rightly directed towards the general and preventive measures guided by research work. As an example is quoted the rapid and organized study of the so-called irritable heart of soldiers, which, though it could hardly have been made in any civil hospital in peace, has given results valuable alike to medical knowledge and to the preventive work of the service. Again, the treatment of men suffering from the effects of poisonous gases has confirmed

¹ London: H.M. Stationery Office. Cd. 8825. To be obtained through any bookseller. Price 6d. net.

the opinion that the methods of administering oxygen commonly followed are wasteful and inefficient, and the results obtained will be applicable in civil practice to the treatment by oxygen of pneumonia and other conditions in which it is indicated. Again, the supply of oxygen to flying men at high altitudes, where it is needed, as in the more familiar case of mountain sickness, has called for the application not only of mechanical ingenuity, but of physiological principles, which, it may be noted, have been founded almost wholly upon scientific work done in French and British laboratories in the last half-century. Of the studies and devices thus called out by these new needs in the upper air it is already clear that some will bring long-needed improvements to the apparatus and methods used in the depths of mines for the rescue of life. It will never be possible to express the results of this scientific work in the medical services in terms of life and money, for the value either of knowledge as such, or of the saving of life and the reduction of suffering cannot be calculated, but on the narrowest commercial view the monetary gain has been vast. Owing to the fact that when an insured person enlists he loses that definition, the annual sum at the disposal of the Committee, which is provided by Parliament at the rate of one penny for each insured person in the United Kingdom, has been seriously diminished, in spite of the fact that an abnormally large number of women have become employed, and thus insured persons; the annual sum available for purposes of medical research has been reduced by about £7,000. We hope in subsequent issues to refer in detail to some of the researches carried out under the direction or with the assistance of the Committee.

SCIENCE IN EXAMINATIONS.

THE earlier part of the new report of the Committee on the Neglect of Science (in education and examination) makes the reader wonder whether the lion has not lain down with the lamb. To have Sir Ray Lankester, the Chairman of the Committee, blessing a system of examination favoured by the Civil Service Commissioners seems to argue the millennium at hand. It only means, however, that even he has learnt to be thankful for so small a mercy as a facultative breach in the defences, hoping that presently it will become practicable. A conference held in May, 1916, under the chairmanship of Lord Rayleigh, O.M., Chancellor of the University of Cambridge, on the neglect of science by the legislative and administrative authorities of the country and by the people generally, unanimously adopted certain resolutions, and the Committee undertook to submit the substance of them to the Government. This was done in interviews with Lord Crewe and the Civil Service Commissioner (Mr. Stanley Leathes). The definite practical purpose was to obtain such alteration in the examinations for first-class appointments in the Home and Indian Civil Service as would lead to an increased attention to the study of the natural sciences in public schools and universities. The Government thereupon appointed two committees, one under the chairmanship of Sir J. J. Thomson, President of the Royal Society, to report on science in the educational system of Great Britain, and the other, under the chairmanship of Mr. Stanley Leathes, to report on the scheme of examination for Class I of the Civil Service. Sir J. J. Thomson's committee advised Mr. Leathes's Committee that it was indispensable that a course of science extending over several years should form a serious part of every candidate's previous education, feeling strongly that if the men with higher scientific qualities, who will undoubtedly be needed in the Civil Services, are to be secured at a comparatively early age by examination, then candidates offering science only (without mathematics) should in future be placed on complete equality with other candidates. The report of Mr. Leathes's Committee advised that while such subjects as languages, literature, and history, are on the whole, and for most

young men, the best preparation for the higher Civil Service, reform is necessary, and should be considered at once. It made the important recommendation that the examination should be divided into two sections—compulsory and optional. For the first section a maximum of 800 marks would be allowed; it would include an essay, English, questions on contemporary subjects, and others on general principles, methods, and applications of science, together with Latin, and one modern language not taken in the second section. Latin, however, might be dropped by those who took two modern languages among the optional subjects; these are fifty-two in number, and in them marks ranging from 100 to 400 would be obtainable, with a possible total of 1,000, so that the possible total for both sections is 1,800. Among the optional subjects are Latin, Greek, French, German, Spanish, Russian, and English, each receiving 200 marks, with 200 more for the history and literature of the same nationalities. Other optional subjects are modern history, economics, politics, law, and philosophy, from which 200 to 100 marks may be earned; mathematics receives 400. A candidate might try for his possible 1,000 marks by selection from the above list, or he might take five branches of natural science, with the choice of chemistry, physics, botany, zoology, physiology, anthropology, or geography; or he might take fewer natural science subjects and fill up from the list of other optional subjects. Sir Ray Lankester says that the Committee's report puts the natural sciences on a really fair footing as compared with classics or any literary study, though the fair working of the new scheme must depend upon the action of examiners, who have it in their power to make it easy or difficult to secure marks in any given subject. Mr. Leathes's Committee has stopped short at securing equal opportunity for all subjects, so that the main purpose of the resolutions of the conference is not accomplished. Schools and the old universities are to a large extent in the hands of teachers of classics, and in the great public schools the head masters are, without exception, "classics," and the importance of the natural sciences as an essential and dominant part of sound education is ignored. Sir Ray Lankester's conclusion is that Mr. Leathes's Committee, "instead of rescuing education from the professional vested interests of the classical schoolmasters, hands back the victim, after many professions of goodwill, to the tender mercies of those who are banded together to starve, torture, and discredit her, and remorselessly to maintain the domination and the pecuniary allurements of the 'classical system.'"

SPECULATIONS ON LIFE.

DR. WILLIAM TIBBLES recently delivered a lecture at Nottingham on creative evolution and the origin of life. Beginning with G. H. Lewes's definition of life as "a series of definite and successive changes of structure and composition which take place in an individual without destroying its identity," he pointed out that the origin of life and the manner in which these changes are brought about have been an object of discussion from ancient times; philosophers being divided into two camps—the Vitalists and the Materialists. The former hold that life is due to a directing agency, and more especially to a vital force different from any other kind of force. The argument that the formation of living organisms is due to a vital principle was set out thus by the lecturer: The distinguishing marks of life in an organism are assimilation, growth, voluntary movement, and reproduction. In an inanimate machine every action leads to the dissipation of energy and retardation of movement; but a living organism can persist in movement and has the power of accumulating energy. In spite of ceaseless changes of matter and energy in its system, a living organism retains its integrity of form, or identity; within limits it is self-feeding, self-repairing, self-moved, and self-controlled. It is autonomous, whereas a machine

is not. These characteristics have never been exactly explained by chemical and physical laws. Materialism, on the other hand, is the theory that matter is the only ultimate reality. The materialist holds that there is no special vital force, but life is the sum of the chemical and physical activities in the organism, and the intellectual powers and moral nature of man, his reason and judgement, are the result of the interactions of matter. Dr. Tibbles referred to the vast amount of support which this theory derives from science. Thus almost all the characteristics of living organisms have been imitated. Movement is not confined to living matter; colloidal substances form semi-permeable films which take up substances in solution just as living cells do, and thus, to some extent, imitate the process of assimilation: crystals grow and multiply; inorganic colloids, under certain conditions, exhibit growth and division. Tracing the chemistry of living tissues and its relationship to ionic action, the lecturer pointed out that every life process is accompanied by changes in the crystalloidal and colloidal substances of the cells. Van't Hoff's formulation of the laws of chemical dynamics has been so fruitful in other fields of organic chemistry that it is believed the metabolic processes of the body are governed by the same laws. The properties of protoplasm may, as Huxley said, result from the nature and disposition of the molecules; but this, in Dr. Tibbles's view, does not prove that the properties of protoplasm are the additive result of the properties of its parts: a living organism contains something quite new. Even if protein were made, and cells resulted, the biologist would have to ask whether the artificial cells bore the hallmarks of vitality. Until lately there was hope that the problems of life would be solved, but the methods of Nature are not those of the laboratory. Thus, while materialism has perhaps failed to establish its thesis, vitalism has certainly revived. Turning next to the recent effort to formulate a theory of evolution of organic material, Dr. Tibbles remarked that he had long held that matter is subject to an evolutionary process, and this opinion was expressed in the preface to his book on *The Theory of Ions*, published in 1908. Since energy is capable of transformation, it is thought that matter, too, may not be constant. According to this view life is a gradual growth, a gradual transformation from the dead to the living by evolution, a change of character, step by step, until from the crude elements of the earth, air, and water, there is evolved the motile and sentient substances of our muscles and nerves. This point of view depends on the theories of evolution, of the transformation of energy, and of ionization, and postulates the existence of intermediary substances between the living and the not-living. The living materials of an organism consist of compounds of carbon, hydrogen, oxygen, and nitrogen, which have plasticity and a capacity for living. Such materials are not drawn directly from inorganic materials, and the argument is that, beginning with the dissociated ions derived from CO₂ and water, their growth into carbohydrates, fats, and proteins is a gradual process of evolution. The proteins, for instance, are formed of amino-acids which have been evolved from simpler bodies containing the necessary elements. In each of these hypothetical changes the substance becomes more plastic, but more unstable; more nearly living, but more easily decomposed. As Dr. Tibbles admits, this idea of creative evolution under the influence of an entelechy or guiding principle is distinctly vitalistic; and by a coincidence in the same year that he wrote his book on the theory of ions, Henri Bergson published *L'Évolution Créatrice*.

BRISTOL ROYAL INFIRMARY.

The histories of some of the metropolitan hospitals, such as Guy's, the London, and Charing Cross, were published before the war, and now a cordial welcome can be extended to the account of one of the oldest, if not the oldest, of the provincial hospitals, the Bristol Royal Infirmary, from its

foundation in 1736 to 1912,¹ when the new surgical wing was opened by the King and Queen. This work, however, is much more than a history of the infirmary and its staff, for it gives a contemporary picture of the social and medical life of Bristol in a kindly gossiping strain and is full of curious items of local interest. There is a refreshing freedom from dull details and statistics which, valuable in their place, do not appeal to the ordinary reader, and the several hundred biographies, many of course necessarily quite short, are human documents and not copies of the proverbial tombstone epitaphs. For much of this intimate information down to 1842 Mr. Munro Smith was indebted to fourteen volumes of most miscellaneous notes and scraps accumulated by Mr. Richard Smith, jun., surgeon to the infirmary (1796-1843), who with Boswellian zeal collected every fragment, some of them rather uncanny, that came his way. The author, indeed, compares his struggle with the material in the fourteen volumes to those ascribed by the author of *Sartor Resartus* to the editor of Professor Diogenes Teufelsdröckh's memoirs. The account of body-snatching a hundred years ago gives a graphic picture of the adventures of teachers and students in their efforts to provide the necessary material for dissection; a teacher of anatomy had a huge bunch of labelled keys by which he could gain access to any churchyard in Bristol or its immediate neighbourhood, and an entry in the old infirmary memoirs states that one student "got up" thirty subjects. In this connexion the author quotes a story, not previously published, of a callous Essex farmer who shot a burglar in his house and, not knowing what to do with the body, thought that it might be useful for dissection, and so packed it up in a box and sent it to the late Sir George Paget at Cambridge, with a letter to say that "he was sending him a man he had shot." There is an interesting note on the rise of antiseptic surgery in the West of England, the way for which was prepared by Dr. W. Budd's views on bacteria. Mr. Munro Smith unfortunately died while the book was in the press, and so will not see the success of his labour of love.

AMENORRHOEA IN WAR TIME.

This subject is discussed in a number of papers in the recent German periodicals (for example, Spaeth, *Zentralb. f. Gynäkologie*, No. 27; Feig, *Med. Klinik*, August 5th, 1917; Strickel, *Zentralb. f. Gynäkologie*, No. 28, 1917). All the authors remark on the great increase of amenorrhoea in women of child-bearing age. They put it down, no doubt correctly, to the defective nutrition under the existing food conditions, and to the fact that many women are now doing men's work. In the Charité-Frauenklinik in Berlin, according to Strickel, cases of amenorrhoea are seven times more frequent than before the war.

Medical Notes in Parliament.

Insurance (Amending) Bill.

Second Reading in the Commons.

In the House of Commons, on November 23rd, Sir Edwin Cornwall explained the provisions of the National Health Insurance (Amending) Bill, a summary of which was published in the *BRITISH MEDICAL JOURNAL SUPPLEMENT* a fortnight ago. The Minister gave some fresh information as to the work already done, and also dealt broadly with some objections already made to the new proposals, promising that they would be met in Committee. In these circumstances the bill was given a second reading without division, and was referred to a Grand Committee, which it is hoped will be set up next week. Sir Edwin said that, roughly speaking, 95 per cent. of the bill represented an agreed measure—the result of conferences with representatives of approved societies and of others concerned. On the whole, the debate supported this view,

¹ *A History of the Bristol Royal Infirmary*. By G. Munro Smith, M.D. 1917. Bristol: J. W. Arrowsmith, Limited. 8vo, pp. 507, 87 figures. 12s. 6d. net.

while making apparent that certain important matters, more especially as to finance, had definitely to be cleared up, and some amendments made in order to meet criticism.

Sir Edwin Cornwall at the outset gave statistics of the work. There are fifteen million insured persons. From 1912 to 1916 the total income was £99,000,000, the contributions amounting to £82,000,000 and the Exchequer money to £17,000,000. During 1916 the employers and employed people contributed £18,500,000, and the State contributed £5,000,000. That money was disbursed in that one year as follows: Sickness and disablement benefit £6,000,000, medical services £4,800,000, maternity benefit £1,250,000, sanatoriums benefit £750,000, administration expenses £2,250,000, and balance invested £8,500,000.

Afterwards the Minister took up the financial proposals, particulars of which have already been given. He emphasized that, except in so far as they are varied and enlarged by an additional grant of £250,000 promised from the Exchequer by the Prime Minister since the report of the Ryan Committee, these proposals follow the recommendations of the Ryan Committee. The proposals now made increase the State provision for women's excess of sickness, and place upon the State the principal part of the residual burden of deficiencies due to special risks, thus relieving the Sinking Fund *pro tanto* of the charge made upon it under the Committee's recommendations. Under the scheme the period for redemption of reserve values which in 1913 was extended to 1932 is further extended to 1947. Sir Edwin explained that this extension releases £1,500,000 out of the £4,500,000 annual income of the money thus retained. In that way they had available £1,500,000 of Sinking Fund, the additional grant of £250,000 already mentioned as promised by the Prime Minister, and £150,000 the continuance of the married women's sickness grant of 1914, making a total sum of £1,900,000. The intention is to apply £280,000 to societies to augment their Women's Ordinary Benefit Fund. It is further proposed to carry £250,000 to the Women's Equalization Fund, which it is proposed to distribute to societies in proportion to the number of married women in the particular society and their expenditure on pregnancy sickness. The Contingencies Fund, of which one-eighth may be called upon for the Special Risk Fund, is put at £1,190,000, and the Central Fund from the State at £150,000.

Sir Edwin Cornwall explained how the amount £1,190,000 was reached. It was proposed to divert from the Women's Sinking Fund £280,000 and from the Men's Sinking Fund £910,000, thus making the total. It is proposed that seven-eighths at least of this money should go direct to societies in proportion to their membership. This was new money to the society. It went to every society in proportion to the membership of the society, and it became society money, available for society purposes. It was not at the present time available for anything but for Sinking Fund purposes. The object of devoting this money to Contingencies Fund was, first, to meet any deficiency disclosed by valuation, and secondly, to augment the Benefit Funds after the next valuation. Under the bill it was proposed that the money, where there was no deficiency, should be held in the Contingencies Fund until the next valuation. Objections had been taken to this and the desire expressed that the money should be held in the Benefit Fund, remaining there to accumulate until after the next valuation instead of remaining in the Contingencies Fund. That amendment the Government proposed to make in Committee.

The Minister afterwards explained the proposal already mentioned that one-eighth of the Contingencies Fund, amounting to £150,000, should be held in reserve to be used only if necessary. Objection had been taken to the title, Special Risks Fund, which was to be given to this allocation, and he said that if members preferred it should be called the Central Fund; that could be done. It was intended to deal with societies where segregation had driven them, or compelled them, to take members engaged in exhausting and hazardous occupations, members living in unhealthy environment subject to exceptionally low standards of life and conditions. The proposal was that £150,000 of the £400,000 of State money should go to the Special Risks Fund. If that was not sufficient for the purpose of relieving any societies of any special liabilities, it was proposed that up to £150,000, one-eighth of the Contingencies Fund, should be made available.

The point to which, however, Sir Edwin Cornwall attached most importance was clearing up a misapprehension that societies with surpluses would be called upon to meet the deficiencies of other societies. He showed that the Contingencies Fund would be obtained through the change in the reserve values arrangement and that under the Act of 1911 the reserve values money was retained by the Commissioners for Parliament to decide what was to be done with that money when the reserve values had been redeemed. The extension of the redemption period enabled the Contingencies Fund to be provided in the way he had described. The Minister afterwards explained in some detail the various changes in the administration and in rules that were to be made under the bill. Touching the amendment in Section 63 Sir Edwin recalled that under this in the original Act it was provided that where undue sickness arose from unhealthy dwellings and insanitary areas the position should be inquired into and some claim made upon those responsible

to relieve the National Health Insurance Fund. As a matter of fact that section had not, he said, had much strength or weight behind it, but it was hoped that with this amendment its use might be possible. Before concluding his review, Sir Edwin Cornwall touched briefly on Clause 31, which deals with doctors on the panel. At the present time the Commissioners can, he reminded the House, remove a doctor from a panel, but cannot remove him from all the panels. He may be removed, for example, from Bermoudey, and yet may continue to practise in Bethnal Green. The desire was to take power to remove a doctor from all panels if removed from any. At the present time the Commissioners had no power to restore a doctor to a panel, and they proposed to take powers to do that. The amendment would enable them to do what was right if the doctor was at fault, and to restore him if such a course was justified. In the course of the discussion, Mr. Godfrey Locker-Lampson criticized the provisions relating to benefits for married women, urging that Parliament should do nothing to discourage the gift of the maternity benefit and the 7s. 6d. a week at a time when it might be needed not only for the women's sake, but for the sake of the health of the child when it was born. He hoped, also, that the increase of the waiting period for maternity benefits—from twenty-six weeks to forty-two weeks—would not be maintained, though he agreed that the existing system had lent itself to a good deal of fraud. Mr. Locker-Lampson made it clear that he presented these considerations in no hostile spirit to the bill, which he thought would go a long way to place societies on a sound financial basis, and to simplify machinery. Other members spoke similarly. Sir Worthington Evans, who did so much as a private member to improve the original bill when it was before the House of Commons, said it was quite true that the Sinking Fund was in part to be diverted, but that Sinking Fund was never available for the purpose of going to any society, except after the period when the reserve values would have been redeemed, a period of not less than twenty years, afterwards extended to twenty-two. Under the new proposal the Sinking Fund would be brought nearer as regards the provision of benefits to the insured person, because after the seven years the surplus which would arise from the Contingencies Fund would be capable of providing immediate benefit. The real effect, therefore, in point of view of insured persons, of this raid on the Sinking Fund was that instead of additional benefit being postponed for twenty-two years, as it was in the 1913 Act, it would be brought within reach at the end of about seven years. When that happened and benefit was distributed, the State's two-ninths contribution would come in so that as far as the insured person was concerned he received the benefit earlier under the provisions of this bill than he would have received it under the Act.

Royal Army Medical Corps.—Major David Davies asked whether a decision had yet been reached as to the comparative rates of pay of those officers in the Royal Army Medical Corps, Territorial Force, who held commissions at the outbreak of the war, and medical men who had been given temporary commissions in the Royal Army Medical Corps since that date. Mr. Forster replied that the matter had been referred to the Government Committee on Officers' Pay, and it was hoped that their decision would be announced shortly. Major Davies asked, in view of the demand for doctors for purely clinical work both here and in France, whether Mr. Macpherson could state the duration of the period of drill which medical officers who joined the Royal Army Medical Corps had to undergo before they were able to give their full time to the clinical duties of their profession. Mr. Macpherson: The duration of the course, which includes not only drill, but military sanitation, anti-gas protection, and the duties of a medical officer with troops in the field, depends on the demands which have to be met for overseas reinforcements, and the shipping available, but usually lasts three weeks. In reply to another question by Major David Davies, Mr. Macpherson said that Surgeon-General Sir Arthur Sloggett exercised control over the R.A.M.C. in France and Belgium under the Commander-in-Chief in France, in the same way as any other head of a department in the field. He was sent to France by Lord Kitchener no doubt because he thought him the best man for the appointment.

The New York Women's Hospital has organized and equipped a unit of ten medical women for service in a base hospital in France.

THE WAR.

PALESTINE: MARCH-JUNE, 1917.

A DISPATCH from General Sir Archibald Murray, late General Officer Commanding-in-Chief, Egyptian Expeditionary Force, dated June 28th, and dealing with the period from March 1st to that date, was published almost simultaneously with the news of the recent successes in Palestine.

The dispatch gives the story of the two attacks on Gaza (March 26th and April 17th). On the first occasion the enemy was severely punished, 950 Turkish and German prisoners being taken and casualties, estimated at 8,000, inflicted. The British casualties were under 4,000. On the second attack the British casualties amounted to some 7,000. Both attacks failed to reach Gaza, but a certain amount of ground was won and retained. Sir Archibald Murray says that no praise can be too high for the gallantry and steadfastness of the cavalry, infantry, artillery, Royal Flying Corps, and all other units which took part in the two battles for Gaza. With regard to the medical services he writes as follows:

The health of the troops has throughout been singularly good. All branches of the medical services under Surgeon-General J. Maher, C.B., deserve the highest commendation for their successful work at the front, on the lines of communication, and in the base hospitals. The presence in the force of a number of civil medical consultants, who have so patriotically given their services, has been of the very greatest value, and they have worked in successful accord with the regular medical services of the army. The Australian Army Medical Corps and the New Zealand Medical Corps have also been remarkable for their efficiency and unremitting devotion.

The dispatch notes that the impossibility of granting leave home on an extended scale rendered the army in the field dependent on rest camps and voluntary institutions for the rest and relaxation so necessary in view of the arduous conditions of campaigning in the desert and in tropical heat. The difficulty of supply was throughout very great. The force was more than usually dependent on animal transport, and important mounted forces were employed, including detachments of the Imperial Camel Corps and the Australian and New Zealand mounted divisions and the Yeomanry. The difficulty of supply was lightened by the pushing forward of the railway. The composition of the infantry is not stated, but seems to have consisted largely of Home and Indian battalions. The dispatch concludes with the promise that the names of officers, non-commissioned officers, and men will be brought to notice for gallant and distinguished services at a later date.

TETANUS IN HOME MILITARY HOSPITALS.

SUMMARIES of the first four analyses of cases of tetanus treated in home military hospitals have already appeared in these columns. We have now received from Surgeon-General Sir David Bruce a fifth analysis of such cases, covering part of December, 1916, and most of the first quarter of the present year.

The Falling Death-rate.

The numbers of cases of tetanus dealt with in the five periods and the rates of mortality are given in the following table, which speaks for itself:

Analysis.	No. of Cases.	Recovered.	Died.	Mortality per Cent.
1914-15	231	98	133	57.7
1915-16	195	99	95	49.2
Aug.-Oct., 1916 ...	200	127	73	36.5
Oct.-Dec., 1916 ...	100	69	31	31.0
Dec., 1916-Mar., 1917...	100	81	19	19.0

In the second analysis the statement was made that "early treatment should be striven for, and if this were done and the antitoxin applied thoroughly, one would not despair of reducing the mortality to, say, 20 per cent. instead of 50 per cent., at which it stands for the past

year." It will be seen that this ambition has been more than realized so far as the returns of the last 100 cases are concerned. This large reduction in the death-rate is most satisfactory, but Sir David Bruce wisely refrains from expressing an opinion as to whether it has been due to the specific treatment or to one of the several other factors involved. Whatever be the cause—the prophylactic dose of serum, better surgical treatment, quicker diagnosis, more thorough therapeutic treatment—the result is gratifying.

Referring to the factor of surgical treatment, it is pointed out that if this could be made entirely successful, by cleansing and sterilization of wounds at the outset, there would be no more cases of tetanus; but while there is some evidence of an improvement in surgical technique much remains to be done. The present analysis repeats and brings up to date figures showing the number and distribution of cases of tetanus treated in home military hospitals since the beginning of the war.

The Lengthening Incubation Period.

Among the last 100 cases we find that where the symptoms of tetanus appeared within ten days of receiving the wound, the mortality was 40 per cent.; where they appeared between the eleventh and twenty-fourth day, it was 25 per cent.; in the remaining 66 cases, with an incubation period greater than twenty-five days, the mortality was 13.6 per cent. In one patient the incubation period was stated as 786 days; but this for various reasons is regarded as a doubtful case which should be ignored for statistical purposes, although, as Dr. Goadby has shown, the tetanus bacillus may remain for a long time quiescent at the site of old wounds. Disregarding this case, the longest incubation was 365 days, and the shortest three days.

Since the beginning of the war the average incubation period has been steadily lengthening. This should probably be attributed in the main to the prophylactic injection of antitoxin. In the first year of the war 47 per cent. of cases had a short incubation period; in the last analysis this had fallen to 10 per cent. Correspondingly the percentage of cases with a long incubation period has risen from 6.4 to 69.

General and Local Tetanus.

In our summary of the last analysis (September 15th, 1917) we printed Sir David Bruce's working definitions of general tetanus and local tetanus. In the present series it was found on examination that 81 cases could be placed in the general group, and 19 in the local group. Among the former there were 58 recoveries and 23 deaths, giving a mortality of 28.3 per cent. All the cases of localized tetanus recovered. There is no evidence to support the view that the presence of a fractured bone complicating the wound is a source of danger heightening the death-rate from tetanus.

Prophylactic and Therapeutic Inoculation.

In six of the cases tetanus is reported to have followed an operation, and one died. In none of these was a prophylactic inoculation of antitetanic serum given before the operation, although the advice of the Tetanus Committee is that this should always be done. As in each preceding series of cases, the mortality among patients who had received no prophylactic injection in France was considerably greater than among those so protected. It should be noted here that the present policy advocated by the Tetanus Committee of the War Office is that four prophylactic injections should be given to every wounded soldier at intervals of seven days, but in periods of hard fighting this might sound a counsel of perfection.

The whole of the 100 cases under review received therapeutic doses of antitetanic serum; in the preceding series all but two were so treated. The considerable reduction in the mortality from 31 to 19 per cent. would not appear, therefore, to be due to this factor, and, as Sir David Bruce states in his conclusions, the evidence as to the therapeutic effect of antitetanic serum is still inconclusive. Once again the figures furnish no case either for or against the intrathecal route as compared with other methods of injection; similarly, from the figures relating to dosage no useful deduction can be drawn.

SURGICAL REQUISITES EXHIBITION.

The Surgical Requisites Association, of 17, Mulberry Walk, Chelsea, a war organization connected with Queen Mary's Needlework Guild, held an exhibition last week at the Grafton Galleries. Various dépôts from all over England, but principally from London, sent examples of their work, and woman's share in the national war industries showed to great advantage. The exhibits were remarkable for ingenuity of design and finished workmanship. It is not so much that new types of appliances have been invented as that many useful, and for the most part simple, modifications have been introduced. Among the many contrivances for the comfort of the patient and for the carrying out of treatment, it is only possible in a brief notice to name a few. Of the larger exhibits the Balkan and Sinclair beds call for special mention. These, as every one now knows, are of incalculable value in the nursing and treatment of dorsally placed injuries, and the association is turning out these beds to keep pace with the increasing demand for them. A useful modification of the McIntyre splint has been introduced in one exhibit. Here the footpiece has been made very wide, so that the natural tendency of the foot to eversion is allowed for, and further, the footpiece is bored on either side to admit of the bandage grasping the foot firmly. A padded malleable metal jaw splint deserves notice: the metal supports to the chin are arranged so as to hook on to a net cap, thus affording firm and equable supports. Strips of Gooch splinting, into which transverse strands of malleable metal had been introduced, so that the splint could be moulded to the limb, seemed a useful modification. The apparatus known as "Hallé's glove" is being made either attached or not to a "cock-up" wrist splint, with strands of elastic to take the place of the paralysed extensors of the hand; thus it is intended to do for the fingers what a toe-raising spring does for foot-plant.

Another noteworthy feature of the exhibition was a large collection of waterproof papier-mâché splints, made on an actual cast of the affected part. The advantages claimed for them are that they are light, accurately fitting, non-inflammable, waterproof, relatively transparent to x rays, and, furthermore, that they lend themselves readily to standardization for the treatment of some of the commoner injuries. Splints made of this material for Colles's fracture, finger-extension splints, and the Acheson splint for abduction of the upper arm, all seemed practical and useful. Apart from splints the exhibition was rich in samples of hospital clothing and utensils, and the promoters have good reason to be proud of a most useful and suggestive venture.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

SURGEON PROBATIONER J. L. NOLAN, R.N.V.R.

Surgeon Probationer J. L. Nolan, R.N.V.R., was reported as killed in action, in the casualty list published on November 24th.

ARMY.

Killed in Action.

COLONEL W. W. HEARNE, D.S.O., A.A.M.C.

Colonel W. W. Hearne, D.S.O., Australian Army Medical Corps, was reported as killed in action, in the casualty list published on November 24th. He received the D.S.O. as a Lieut.-Colonel on June 4th, 1917, so his promotion to administrative rank must have been recent.

MAJOR N. J. BULLEN, A.A.M.C.

Major N. J. Bullen, Australian Army Medical Corps, was reported as killed in action, in the casualty list published on November 23rd.

CAPTAIN JOHN ALSTON, M.C., R.A.M.C.(S.R.).

The name of Captain J. Alston, R.A.M.C., was given as killed in action, in the casualty list published on October 29th. In the BRITISH MEDICAL JOURNAL of November 3rd was published an obituary notice in which it was assumed that the Captain Alston killed was Dr. James Alston who took the licences of the Irish Colleges in 1911. We have since been informed that this gentleman died last year. It was Captain John Alston of Glasgow who was killed.

He graduated M.B., Ch.B.Glas. in 1916, and held a commission in the R.A.M.C. Special Reserve. The award to him of the Military Cross was gazetted on October 18th, 1917.

Died of Wounds.

MAJOR W. L. MACLEAN, C.A.M.C.

Major W. L. Maclean, Canadian Army Medical Corps, was reported as having died of wounds, in the casualty list published on November 22nd. He was born in Western Canada, received his early education in Nova Scotia, and graduated in medicine at Dalhousie University in 1907. In February, 1915, he went to France with a Canadian stationary hospital, and served with various medical units—Canadian and British. At the time of his death he was attached to a British casualty clearing station. Major Maclean was one of the most promising of the younger members of the medical profession in Canada. He was a first-rate surgeon, a good organizer, and a very hard and conscientious worker. He was extremely popular with all his colleagues. His death is a great loss to the armies in the field, and to the medical profession.

CAPTAIN L. L. MCKEEVER, R.A.M.C.

Captain Louis Lawrence McKeever, R.A.M.C., was reported as having died of wounds, in the casualty list published on November 22nd. He was educated in Dublin, and took the L.R.C.P.I. and L.R.C.S.I. in 1914. He joined the R.A.M.C. as a temporary lieutenant on February 14th, 1915, and was promoted to captain after a year's service. He was attached to the Royal Scots when killed.

Died on Service.

CAPTAIN N. J. H. GAVIN, M.C., R.A.M.C.

Captain Niel John Hay Gavin, M.C., R.A.M.C., was reported as having died on service, in the casualty list published on November 23rd. He was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1904. He then took up lunacy as a speciality and served as assistant medical officer successively in the Norfolk County Asylum, in the West Riding Asylum at Wakefield, and in the Three Counties Asylum at Hitchin, Hertfordshire. Joining the R.A.M.C. as a temporary lieutenant nearly two years ago, he was promoted to captain after a year's service and received the Military Cross on June 3rd, 1917.

Wounded.

Major W. M. A. Fletcher, Australian A.M.C.

Captain C. F. Backhouse, R.A.M.C.(T.F.).

Captain R. T. Caesar, R.A.M.C. (temporary).

Captain H. P. Caithness, R.A.M.C. (temporary).

Captain T. H. Carson, Canadian A.M.C.

Captain J. F. Edmiston, R.A.M.C.(T.F.).

Captain A. H. Falkner, R.A.M.C.(T.F.).

Captain G. M. Forbes, Canadian A.M.C.

Captain D. H. A. Galbraith, R.A.M.C. (temporary).

Captain G. Hislop, R.A.M.C. (temporary).

Captain D. A. Macleod, Canadian A.M.C.

Captain W. L. Millett, Australian A.M.C.

Captain B. R. Mooney, Canadian A.M.C.

Captain E. L. Morgen, Australian A.M.C.

Captain W. W. Morrison, R.A.M.C. (temporary).

Captain W. A. Murphy, R.A.M.C. (temporary).

Captain J. R. Paul, R.A.M.C. (temporary).

Captain E. H. Scholefield, R.A.M.C.(T.F.).

Captain W. H. Scott, Canadian A.M.C.

Captain D. P. Thomas, R.A.M.C. (temporary).

Captain H. W. Whybock, Canadian A.M.C.

Lieutenant A. S. Porter, Canadian A.M.C.

Lieutenant A. Rodd, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Brown, G. L., Lieutenant Loyal North Lancashire Regiment, youngest son of Dr. Andrew Brown, of Hatch End, Middlesex, killed November 15th, aged 31. He got his commission on November 24th, 1914.

Butlin, Sir Guy, Bt., Captain and Adjutant Cambridgeshire Regiment, only son of the late Sir Henry Butlin, President of the Royal College of Surgeons of England, and of the British Medical Association, reported wounded and missing on September 16th, 1916, now presumed killed on that date, aged 23. He was born in 1893, educated at Harrow and at Trinity College, Cambridge, where he took his degree with honours in June, 1914, and had entered the Inner Temple, when he took a commission on August 26th, 1914. He went to the front in February, 1915, and was promoted to captain in the following June. He

was killed while bringing in a wounded officer. He succeeded his father as second baronet in 1912, and by his death the baronetcy is left without an heir.

Saundby, William Spencer FitzRobert, Second Lieutenant Yorkshire Regiment, in his 19th year, youngest son of Dr. Robert Saundby of Birmingham, a former President and Chairman of Council of the British Medical Association. He was educated at West House School, Edgbaston, and King Edward's High School, Birmingham. He entered the army through Sandhurst in the spring of 1916 and joined the Royal Flying Corps. He went overseas in October, 1916, and was reported missing on November 17th, 1916. It was believed that he had had to make a forced landing and been taken prisoner, but as no news has since been heard of him this hope has been abandoned.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SPECIAL Supplement to the *London Gazette*, issued on November 26th, contains a further list of awards for gallantry and distinguished service in the field. The acts of gallantry for which the decorations have been awarded will be announced in the *London Gazette* as early as practicable. The following medical officers are awarded the decorations indicated:

Bar to the Distinguished Service Order.

Major (temporary Lieut.-Colonel) Patrick John Hanafin, D.S.O., R.A.M.C. (D.S.O. gazetted January 14th, 1916).
Temporary Captain Robert McCowan Hill, D.S.O., M.B., R.A.M.C. (D.S.O. gazetted May 16th, 1916).

Distinguished Service Order.

Majors William Bannerman Craig, A.A.M.C.; William Allan Hailes, A.A.M.C.; Harrie Bertie Lee, M.C., A.A.M.C.; Kenneth MacCormick, N.Z.M.C.; Robert Maxwell McMaster, A.A.M.C.
Captain and Brevet Major Henry Forbes Pantou, M.C., M.B., R.A.M.C.
Temporary Captains James Churchill Dunn, M.C., M.D., R.A.M.C.; Ernest Harrison Griffin, M.C., M.D., R.A.M.C.

Bar to the Military Cross.

Captains: Charles Herbert Leadman, M.C., A.A.M.C. (M.C. gazetted July 18th, 1917); George Reginald E. G. Mackay, M.C., M.B., R.A.M.C. (M.C. gazetted September 22nd, 1916); Patrick Joseph Francis O'Shea, M.C., A.A.M.C. (M.C. gazetted November 18th, 1917).

Temporary Captains: William Thomson Brown, M.C., M.B., R.A.M.C. (M.C. gazetted September 26th, 1917); Charles Reginald R. Huxtable, M.C., M.B., R.A.M.C. (M.C. gazetted July 18th, 1917); Charles Joseph O'Reilly, M.C., M.D., R.A.M.C. (M.C. gazetted November 4th, 1915); John Finlayson McG. Sloan, M.C., R.A.M.C. (M.C. gazetted July 18th, 1917); Gideon Walker, M.C., M.B., R.A.M.C. (M.C. gazetted November 14th, 1916).

Temporary Lieutenant (temporary Captain) Henry Alphonsus Harbison, M.C., M.B., R.A.M.C. (M.C. gazetted August 25th, 1916).

Military Cross.

Captains: William Norman Abbott, N.Z.A.M.C., Douglas Lewis Barlow, A.A.M.C., Charles Henry Brennan, R.A.M.C. (S.R.), John Herald B. Brown, A.A.M.C., George Crawshaw, M.B., R.A.M.C., Arthur Curtis, A.A.M.C., Frederick Ellis, R.A.M.C., Stuart Galloway Gibson, A.A.M.C., William Evans Graham, M.B., R.A.M.C., Charles Edward K. Herapath, R.A.M.C., Frederick William Kemp, N.Z.A.M.C., David Mackie, M.B., R.A.M.C. (S.R.), James Purdie, R.A.M.C. (S.R.), James Rafter, M.B., R.A.M.C. (S.R.), Stanley Arthur Railton, A.A.M.C., Edmund Lewis Reid, S.A.M.C., Hugh Arthur Sandford, M.B., R.A.M.C., Frederic Battinson Smith, R.A.M.C., Edwin Cyril W. Starling, R.A.M.C. (S.R.), Adam Annand Turner, M.B., R.A.M.C., Harry Whitaker, M.B., R.A.M.C., Eric William B. Woods, A.A.M.C.

Temporary Captains: Douglas Erith Derry, R.A.M.C., Thomas Duncan, R.A.M.C., Andrew Gaston, R.A.M.C., John Lewis A. Grout, R.A.M.C., John Charsley Mackwood, R.A.M.C., William Strolley Martin, M.B., R.A.M.C., John Louis Menzies, M.B., R.A.M.C., James Bertram Mitton, M.B., R.A.M.C., John Henry Morris Jones, R.A.M.C., Joseph Herbert Porter, M.B., R.A.M.C., Norman Pallister Pritchard, R.A.M.C., Alan Randle, M.D., R.A.M.C., William Logan Scott, M.B., R.A.M.C., John Aylmer Tippet, R.A.M.C., John Wilfred Watthews, M.B., R.A.M.C., Henry Dewi H. Willis-Bund, R.A.M.C.

Temporary Lieutenant (temporary Captain) Raymond John Clausen, R.A.M.C.

Lieutenant Henry John Henderson, M.B., R.A.M.C.

The Distinguished Conduct Medal is bestowed upon one non-commissioned officer and five privates of the R.A.M.C. and one non-commissioned officer of the A.A.M.C.

THE late Captain Harold Ackroyd, V.C., R.A.M.C., who was killed in France, left estate valued at £39,748 gross.

England and Wales.

LONDON COUNTY COUNCIL AND THE PROPOSED MINISTRY OF HEALTH.

In a report presented by the Public Health Committee to the London County Council on November 27th the draft bill for the establishment of a Ministry of Health, submitted by National Insurance organizations to the Prime Minister on October 11th, was criticized on the ground that, while it proposed the formation of a Ministry of Health and would transfer to it various powers at present attaching to a number of Government departments, it did not transfer the powers of the Local Government Board relating to housing, town planning, drainage, water supply, and the like, the proper exercise and development of which were essential to the health of the community. It appeared to the Committee inevitable that one of two things must happen—either environment must be separated from health or the powers relating to environment must also be transferred to the new Ministry. The Committee was strongly of opinion that the former course was undesirable in the interests of efficient administration. The Committee also regarded the proposal to set up hybrid committees of representatives of different authorities—some of them non-elected bodies—to administer public moneys provided out of the rates or national funds as being contrary to the principles of local government. The Council adopted a recommendation that the functions of a Ministry of Health should not be separated from those of the department entrusted with the central supervision of local powers; and also that any further powers to be granted by Parliament with regard to public health should form part of the existing system of local government. A rider was adopted suggesting that a public inquiry be held as to the cost of the policy and the position of local authorities.

LONDON ASSOCIATION OF MEDICAL WOMEN.

At a meeting of the London Branch of the Medical Women's Federation on November 13th, with Lady Barrett in the chair, it was resolved to draw the attention of the Food Controller to the national importance of safeguarding the supply of milk and sugar for all young children. A discussion was held on the two questions referred to the associations at the annual meeting of the Medical Women's Federation: (a) The advisability of establishing a Ministry of Health; and (b) which departments required more urgently to be dealt with by such authority. Dr. Mary Scharlieb said that all were agreed that the formation of a Ministry of Health was a national necessity in order that the medical work now performed by various departments might be co-ordinated. Dr. Ethel Bentham, discussing the proposals of certain members of the National Insurance Committee, said that as long as the urgent question of housing was postponed, the other suggested arrangements for crèches, hospital beds, etc., would be of comparatively little use. It was essential that the Ministry of Health should, as soon as established, take control of the medical services now rendered under the Poor Law administration and also of the housing powers of the Local Government Board. Lady Barrett spoke of the necessity for unifying and co-ordinating the authorities dealing with infant welfare centres and with the prevention of infantile mortality. Dr. Jane Walker held that the Local Government Board, the Board of Education, and the National Insurance Commission should be united and work as one central authority. Local Health Councils would then be formed, uniting all the services with the medical officer of health as chief medical officer, to deal with matters locally. Housing must form part of any scheme. Dr. Eleanor Lowry pointed out the importance of establishing a proper basis of work for nurses, so that they might earn a living wage and have an eight hours working day. Dr. Sophia Jevons, in a paper on the medical services now included under the Poor Law administration, said that the Public Health Act, 1875, empowered a sanitary authority to open any hospital. This authority should take over the infirmaries and thus banish the pauper taint.

INSURANCE BENEFITS IN WALES.

Some remarkable figures relating to the administration of the Insurance Act in Wales were submitted at a welcome

given on November 22nd by the Lord Mayor of Cardiff (Alderman Roberts) to the members of the Association of Welsh Insurance Committees. The President of the Association, Mr. J. E. Tomley, said that in July, 1914, the number of insured persons in Wales was 632,923 males and 150,246 females, a total of 783,169. On October 1st, 1917, the numbers were 586,521 men and 195,050 women, total 781,571, showing a decrease in the three years of 1,598. But the decrease was entirely on the men's side, and reached the large figure of 46,402; the number of insured women, on the other hand, increased by 44,804. This, of course, is due almost entirely to the changed conditions of male and female labour owing to the war. It was stated that the number of insured persons in Wales was approximately one-third of the whole population. Sir Thomas Hughes, Chairman of the Welsh Insurance Commission, said the sickness benefit paid during 1916 to men amounted to £291,000, to women £46,000. Maternity benefits paid to men's wives amounted to £72,000, and direct to women members £2,766. Disablement benefits for men amounted to £53,000, for women to £12,000. The medical and sanatorium benefits amounted to nearly £300,000. He claimed that during the year insured persons in Wales had received in money or money's worth nearly a million of money. In the course of further proceedings (at the fourth annual meeting of the association), a paper was read by Mr. F. Llewelyn Jones of the Flintshire Committee advocating the establishment of a Ministry of Health, and after discussion it was resolved:

That it is essential in the national interest that a Ministry of Health should be created at the earliest possible date, the Ministry to be represented by a Minister of Cabinet rank responsible to Parliament, and that all the health functions of the existing central authorities should be transferred to and vested in the proposed Ministry of Health, inasmuch as it is not considered advisable that any of the existing central departments should be constituted a Ministry of Health.

A NEW NATIONAL FUND FOR WALES.

At the invitation of Mrs. Lloyd George, Chairman of the "National Fund for Welsh Troops," and Sir Owen Thomas, Chairman of the "Welsh National Fund," a National Conference is being held at the Shire Hall, Shrewsbury, on Friday, November 30th, for the purpose of establishing a "Welsh National Fund for the Welfare of the Sailors and Soldiers of Wales and their Dependants." The object is to provide for the further welfare of the persons named without relieving the State of any of its obligations. It is understood that the promoters of this extension of the work carried on, or proposed to be carried on, by various funds, have been largely guided by the views of Colonel Sir Robert Jones on the urgent need of providing for the wants of discharged and disabled soldiers over and beyond the provision to be made by the Government. It is intended to entrust the work to a National Committee consisting of Lords Lieutenant, members of Parliament, chairmen of county councils, mayors of boroughs, chairmen of urban and rural district councils, chairmen of War Pensions Committees, representatives of discharged and disabled soldiers and sailors, and of labour organizations, and for the furtherance of the fund an early appeal is to be made to the people of Wales. The constitution of the National Committee appears, on the whole, to be widely based, but it does not include a direct representation of the medical profession.

THE TREATMENT OF TUBERCULOUS PERSONS.

At the meeting of the London Insurance Committee on November 22nd, the chairman, Mr. Kingsley Wood, reported that he and other members of the Committee had attended a conference called by the President of the Local Government Board to consider the treatment of tuberculous persons in London. The Insurance Commissioners, the London County Council, and the Metropolitan Asylums Board, were also represented. Negotiations were still proceeding, and it was hoped that the outcome would be a comprehensive scheme for both insured and uninsured persons, the distinction between whom was arbitrary. On the basis of the Astor report, giving one sanatorium bed and one hospital bed to every 5,000 of the population, London would have 904 sanatorium beds and an equal number of hospital beds. For the insured population of 1½ million in London, the figures would be 300 sanatorium

and 300 hospital beds. At the present time there were only about 350 beds in all available for the ordinary civilian insured persons; 120 others were occupied by service men. Under a comprehensive scheme, such as had been adopted in Liverpool, London would become entitled to a grant of £90,000 for sanatorium benefit, and he hoped that through the good offices of the London County Council a great step forward in this direction would shortly be taken.

Scotland.

WOMEN MEDICAL STUDENTS IN EDINBURGH UNIVERSITY.

At the present time 285 women are studying medicine in the University of Edinburgh. Those who have proceeded to graduation during the past months are not included. Forty-two new students began in the past summer session, and sixty in the present winter, making 102 in all for the year.

INSPECTION OF SCHOOL CHILDREN.

The report of Dr. G. Arbuckle Brown, principal medical officer of the Govan School Board, contains some points of interest. Govan is a suburb of Glasgow, with a population of over 80,000. It contains forty-one schools, for the medical inspection of which the board makes provision. They comprise thirty-two public schools, two special schools for physically and mentally defective children, and seven voluntary schools. During the year 8,642 routine examinations, 9,259 non-routine examinations, and 2,731 special examinations in the investigation of necessitous children were made. The report states that the total number of children on the roll of the special schools was 420, classified as follows: rickets 175, tuberculous disease 92, nervous diseases 86, circulatory disease 20, pulmonary disease 8, and other conditions 39. There was a total of 151 mentally defective children, classified as follows: "high grade" 56, "medium grade" 71, and "low grade" 24.

Correspondence.

THE "HAEMOGREGARINE" OF TRENCHELL FEVER.

SIR,—Ever since the publication by McNee and his fellow workers of their classical investigations on trench fever this disease has come to be recognized by medical officers in France as a very definite clinical entity. Although, however, the condition has been carefully studied by a number of competent laboratory investigators with a view to determining its etiology, it can, I think, rightly be said that no one has as yet clearly demonstrated the existence of a visible parasite as the responsible causative agent.

In this respect the recent appearance, in the pages of the *Lancet* of September 8th, 1917, of a communication by Captain Lyn Dimond entitled, "Trench fever or P.C.O. associated with the presence of a haemogregarine," has excited widespread interest, for here, according to the author, is a parasite which is not only of considerable size but which can be demonstrated by a relatively simple technique.

I need not here discuss the misapplication of the established nomenclature of protozoological literature which trammels Captain Dimond's description, for this aspect of the question has been already sufficiently dealt with in the pages of the *Lancet* for September 22nd by Dr. Low and by Mr. Clifford Dobell. The real problem that presents itself is this: Of what nature are the bodies that Captain Dimond finds in his blood films?

During a recent visit to London I have had the opportunity of examining certain of Captain Dimond's preparations at the Hampstead Hospital, and since returning to France I have seen preparations made by a number of workers who have followed Dimond's technique. The work done in France has confirmed the Hampstead findings in that preparations of venous blood taken from cases of trench fever and haemolyzed in distilled water before being stained have shown the presence of bodies which are identical with those depicted by Dimond in

Figs. I, II, III, IV. The important point, however, lies in this, that using the same technique and the same distilled water control specimens of blood taken from healthy individuals show the same bodies. This finding, coupled with the fact that the search through direct smears of blood stained without any previous laking process have proved quite fruitless, brought under suspicion the distilled water used as the laking reagent.

This suspicion I have succeeded in confirming in the following manner. A specimen of distilled water that had been used to lake specimens of blood, which on staining yielded the bodies referred to, was passed through a Berkefeld filter. The scraping from the candle yielded in small numbers a very active flagellate. This organism was transferred to distilled water containing a minute trace of normal human serum, and at the end of six days at room temperature gave a rich culture of flagellates. Stained preparations of this culture show Dimond's gametocytes as pictured in Figs. I, II, III, IV. The organism is about the size of a red corpuscle, young forms being slightly smaller and older forms slightly larger than a red cell. It has bright blue cytoplasm which is coarsely reticular, and contains numerous vacuoles. Dimond's "nucleus *de reliquat*," however, is really a trophonucleus, while his peripheral deep red-stained nucleus rich in chromatin is really a kinetococcus. The creature is endowed also with two flagella which have not been depicted or described. Further, the deeply staining globules which Dimond takes to represent division of the nucleus are not nuclear at all. They have none of the staining characters of chromatin, and are really large spherical metabolic granules. Again, certain individual flagellates as they grow ingest large numbers of bacteria and then die. These individuals when stained present no more than a degenerated trophonucleus surrounded by more or less radially arranged bacteria. These latter are Dimond's merozoites (Fig. V).

From another specimen of distilled water passed also through a Berkefeld filter I have obtained preparations showing in numbers Dimond's fully developed merozoite (Fig. VI), and also his micromerozoites (Fig. VIII). Both these bodies are really large bacteria in which, with Romanowsky staining, the chromatinic material has aggregated itself in the centre of the bacillus.

It seems impossible, therefore, to avoid the conclusion that Dimond has mistaken for the causative agent of trench fever a flagellate protozoan and a bacillus that are present in impure distilled water. Trained observers have long ago called attention to this source of error in dealing with blood films treated by the laking method, and they are familiar, to take an instance, with the description given by Captain Archibald in the Wellcome reports of a similar flagellate organism found by him in distilled water in his laboratory in Khartoum.—I am, etc.,

HERBERT HENRY, M.D.,

Captain R.A.M.C.

November 3rd.

THE CENTRAL POOL AND THE INVALIDED SOLDIERS' FUND.

SIR,—I wish to draw the attention of every panel practitioner to the account of a discussion at a meeting of the London Panel Committee, held on November 20th, on the "regulations for the medical attendance of discharged disabled sailors and soldiers," which is reported in the SUPPLEMENT to the JOURNAL of November 24th on p. 103, and particularly to the following passage therein: "There was no statutory obligation on the part of the Commissioners to consult Panel Committees, but the Commissioners made it clear that they did recognize a moral obligation to consult the profession fully." That refers to the introduction of new regulations generally. On the motion, which was passed, to take counsel's opinion on "the rights and powers of the Panel Committee under the Acts and regulations," Dr. J. V. C. Denning pointed out that the Commissioners were *not* bound to consult with Panel Committees before making any changes in the regulations; that they were *not* bound to give six to eight weeks' notice of such changes as they proposed; and that they *had* the power to substitute a dividend for a capitation scheme of payment.

Over twelve months ago I drew attention to the first two of these three points in certain letters to the JOURNAL, and insisted that this position was the direct and necessary consequence of the fact that our agreements were made with the Insurance Committees of counties and county

boroughs and not with the Commissioners direct. I am convinced that this arrangement is at the bottom of our present troubles and difficulties, and that it will be a never-ending source of friction unless and until every panel practitioner's agreement is with the Commissioners. Now they have an absolutely free hand to alter our terms of service anyhow and any when they like. They admit a moral obligation to consult us with regard to changes, but what man with half an eye to business would submit to an agreement when the obligations on one side were only moral and on the other legal? I cannot imagine anything more crass and stupid.

I have been told that the change I suggest could only be made by an alteration of the Acts. I am doubtful about that, but it is one of the points upon which the London Panel Committee might well take counsel's opinion; also as to its advisability. If it cannot be done under the present Acts, then an alteration of them to permit it is the most important thing the profession can fight for at present.—I am, etc.,

Ashton-under-Lyne, Nov. 24th.

SAM'L. CRAWSHAW.

THE FUTURE OF THE POOR LAW MEDICAL SERVICE.

SIR.—Dr. Withers Green asks for short replies to his query, in his letter in the JOURNAL of November 17th, p. 673. Do you wish the Poor Law medical service to be merged into the present and future general insurance scheme? As there are a good many men who perhaps do not study their JOURNAL and SUPPLEMENT very carefully, may I point out to them that it is suggested by the Association that the post of Poor Law doctor be abolished, and that Poor Law patients should become insured patients. I think the large majority of men who hold these appointments will quickly and decisively answer Dr. Withers Green's query in the negative. Speaking as a country practitioner, I should be sorry to attend these people at a rate a good deal in excess of the present insured rate. They consist largely of old people who are always more or less ill, and require constant attention. Moreover, I am sure this proposed change would not be in their interests.

As I understand there are some four thousand men holding these appointments, I hope they will communicate with Dr. Withers Green. Otherwise they must not be surprised if, at no distant date, they find themselves deprived of their appointments owing to their own slackness in answering a simple question.—I am, etc.,

Gillingham, Dorset, Nov. 24th.

R. W. MORGAN, M.D.

MIDWIVES (IRELAND) BILL.

SIR,—In the BRITISH MEDICAL JOURNAL of July 29th, 1916, and subsequent issues I felt bound to criticize the attempt of a "committee consisting of distinguished medical gentlemen" to extend to Ireland the Midwives Act of Scotland amended in such a way as to inflict additional labour on the dispensary medical officers of Ireland, and deliberately to exclude them from remuneration accorded to all other medical men working under the proposed Act. The correspondence in the JOURNAL extended over many weeks, with the result that the committee of distinguished medical gentlemen considered it expedient to hand over to the Local Government Board the charge of the bill. I presume they saw it would be a hazardous proceeding to out-pace the feelings of nearly 1,000 medical men in this country.

The bill, with its objectionable proposal, is now before Parliament—backed by the Chief Secretary and the Solicitor-General—and will probably become law. I suggested in my first letter, "in the event of the Act being extended to Ireland, an amendment exempting dispensary medical officers who have trained midwives employed under the Medical Charities Acts in their districts from the obligation of attending maternity cases on red tickets with registered or unregistered handy-women where the service of the trained midwife is available."

I was promised the fulfilment of that condition, but there is no such provision in the bill. I would therefore ask to have it included after Clause 22. You must be aware that cases of emergency provided for in the bill are not likely to occur where those seeking treatment under the Medical Charities Acts honestly desire to avail themselves of the assistance of the trained midwife provided

for them free of charge under those Acts; however, such cases can be multiplied indefinitely where people consider it more desirable to employ a handy-woman who remains in residence during the lying-in period, and washes and housekeeps for the household, while the unremunerated dispensary doctor is compelled to take over the work, and also the opprobrium of the untrained midwives' too-frequently fatal mistakes.

Where in the bill are we empowered to expel untrained women from the charge of a "Poor Law emergency case" and substitute our trained nurse? No such provision is made. Is the Local Government Board prepared to publish a rule empowering us, if summoned on a red ticket, to refuse to take up a case where the patient or her husband refuses the attendance of the midwife provided under the Medical Charities Acts? Should they insist on retaining the services of the untrained nurse, must the dispensary medical officer continue in attendance though specifically excluded from obtaining any remuneration by the Irish Midwives Bill?

As to what the Midwives Board might do under Clause 5 (10) we are perfectly indifferent, as we take nothing for granted.

Personally I believe the handy-woman should be suspended at once wherever she is found at work, but since the House of Commons is so particular about vested interests—even those prejudicial to human welfare—as not to intervene directly and abolish them even under such circumstances, I would suggest it would be much cheaper in this country—apart from public safety and advantage—to pension handy women than to incur the cost of giving effect to the proposals of this bill. However, that aspect of the matter does not immediately arise, and is one more for county councils.—I am, etc.,

Ardinnan, co. Tipperary, Nov. 26th.

J. POWER, M.B.

HOW IS THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS TO BE MADE?

SIR,—With much of Dr. Garvie's letter on this subject I am in complete sympathy. I think, however, the criticism on Dr. Sutherland's memorandum is too severe, and, in the circumstances, unjust. This memorandum was drawn up by Dr. Sutherland not on his own initiative, but in response to the request of a subcommittee representing the Manchester Insurance and Medical Committees. This subcommittee, I think, felt that, with a little more care on the part of some practitioners, some cases of pulmonary tuberculosis might be notified at an earlier stage. It was with the object of directing attention to, and securing earlier notification of, these comparatively advanced cases that this memorandum was issued. If it had been a question of the diagnosis of incipient cases only, the memorandum would have been largely irrelevant.

Though I personally had occasion to dissent from one or two of Dr. Sutherland's conclusions, I quite concurred with the feeling of my colleagues that Dr. Sutherland had secured the immediate object in view, and that he had accomplished a difficult and somewhat invidious task satisfactorily. It is open to question whether such earlier notification as we had in view would be of any great value to the individual patient. But notification gives the M.O.H. a chance of dealing with insanitary conditions; it may be useful for statistical purposes; it may result occasionally in the recognition of cases which would otherwise escape detection at the moment; it is now a legal obligation. It was therefore desirable to secure notification before some of these patients were moribund or dead.

Of course, it must be obvious to any one with experience of this disease that what is wanted is the earliest possible recognition of incipient cases. But at present that is a matter of extreme difficulty. If all cases were recognized and treated before gross lesions had developed, it appears certain that much better results would be shown; but there can be no doubt that in such improved results there would then appear many cases which would have recovered in any circumstances, without recognition and without treatment. What one feels to be uncertain is whether we have any treatment which can be relied on really to control, to any great extent, the natural course of events. Rest and change of air are no doubt factors of considerable practical importance, but something more is wanted in order to satisfy ideal therapeutic requirements.

I venture to suggest that for the present the efficiency of institutions for the treatment of pulmonary tuberculosis be estimated rather by their contributions to our knowledge of the numerous complex problems of diagnosis and immunity, than by statistics of "cures" which may be entirely misleading. If such a standard were set up, more money might be invested before long in research by public authorities anxious to make some headway towards a solution of the tuberculosis problem; and there might also be less disposition on the part of certain tuberculosis experts to shift all the blame for comparative failure on to the shoulders of the long-suffering general practitioner.—I am, etc.,

Manchester, Nov. 26th.

J. STAVELEY DICK.

SIR,—In your last issue Dr. Garvie has a letter in which he criticizes sanatorium benefit as administered in his own area, and apparently objects to a memorandum by Dr. Sutherland. In view of this letter, I think your readers should be informed that this memorandum was drawn up by Dr. Sutherland at the request of the Manchester Panel Committee, was discussed with them clause by clause, and finally issued by the Local Medical and Panel Committee to all practitioners in Manchester.

The reasons for this step were too many to trouble your readers with, but the chief was that the Insurance Committee had become convinced that the co-operation of practitioners was essential to any scheme for dealing with tuberculosis, and asked for the assistance of the Panel Committee to obtain this. The Panel Committee found that the ideas of practitioners about the early diagnosis of phthisis were so conflicting that they thought it wise to have an up-to-date statement by the local expert on the subject as a guide.

I am not in any way traversing Dr. Garvie's opinions, but wish to make it clear that his criticisms of Dr. Sutherland's pamphlet must be at least shared, if not entirely borne, by the Manchester Panel Committee.—I am, etc.,

R. G. MCGOWAN,

Honorary Secretary, Manchester Panel Committee.

Manchester, Nov. 26th.

LAY RADIOGRAPHERS AND ELECTRICIANS.

SIR,—“Electro-therapist” does well to urge the Medico-Political Committee to consider the question of laymen in medical electricity. As one of the medical men whom he censures for supporting a lay body in granting certificates to lay people I can the more keenly invite this investigation. His criticism of our own efforts is easily met. The general public and the mass of the medical profession are both absolutely indifferent in the matter of qualification to carry out electro-therapy. The latter are more to blame, for their medical training should have taught them wisdom. These lay bodies are censured for having been more intelligent and conscientious than the profession, and for endeavouring to supply people with some training to carry out this work, for which the war makes so great a demand. In teaching or examining these people we are under no delusion that they are perfect, but we do feel that their training affords to the patients some protection from the doctor who merely orders “electricity,” or “ionization, but on no account to use the galvanic current.” These certificate holders are quite capable, under skilled medical control, of safely and effectively carrying out the ordinary treatments of which some thousands are given every day in the military hospitals. It is obvious that in the present state of the medical profession in this country it would be an absolute impossibility to find a sufficient number of medical men qualified in this speciality to do the routine work. On the other hand, many doctors do not hesitate to leave the prescription of electric treatment to the masseuse and do not trouble to inquire if she has any knowledge of this subject.

Let the Medico-Political Committee get to work as soon as may be, and let it see to it that medical men no longer call for prescriptions of electric treatment or for investigations of electrical reactions by unqualified people.

If the mass of the profession can be prevailed upon to act professionally, there will be no “detriment to the public and the profession,” and that is, after all, the aim of those who assist in the granting of these certificates.—I am, etc.,

November 21st.

ELECTRO-THERAPIST.

MEDICAL CERTIFICATES.

SIR,—Having regard to the Government's new scheme for the medical re-examination of men for the army, specialists and medical practitioners will no doubt now be consulted in large numbers and asked to give certificates for use before appeal tribunals.

As is known, there have been, and no doubt will be, many cases of false personation; so may I suggest that doctors should take all necessary precautions before giving certificates to men who are strangers to them—for example:

1. Require the man to sign his name on the certificate before he parts with it, so that it may be compared with the man's signature on his application to the tribunal.
2. Require in the case of a Russian the production of his Alien Registration Card, which has his photograph on.
3. State on the certificate the name and address of the doctor or person by whose suggestion or recommendation the man says he has been advised to consult him.

This latter precaution may seem strange, or perhaps be thought unprofessional; but may I point out that, in the present anxious times we are going through, doctors have a duty to the State as well as to the man who consults them, and should not forget that the object very often of their being consulted at all is not any real anxiety of the man about his health, but to try and get exempted from military service of any kind.

A man does not now need a certificate from any well-known specialist to get a new examination and be "regraded." His own medical or panel doctor is sufficient.

Of course the medical profession cannot help being consulted, but they might, I think, help the tribunals and the authorities as much as they can, and not let the obtaining of certificates become a scandal. At one sitting of a tribunal over which I presided lately we had certificates from the same specialist in no less than five cases, and in two of them the specialist was not a specialist in the man's alleged trouble; and in asking one why he consulted this particular specialist, he said he was told he would be more likely to get off if he had one from him. "Why didn't you bring a certificate from your own doctor?" I asked a man, to which he replied in an unguarded moment: "That would have been no good. He knows there's nothing really wrong with me." *Verb. sap. sat!*—I am, etc.,

F. BRINSLEY-HARPER,

Member of the Appeal Tribunal for London,
and of the Russian Tribunal.

London, E.C., Nov. 26th.

BIPP AND SIMILAR PASTES MADE WITH
PARAFFIN: A WORD OF WARNING.

SIR,—If the paraffin is not perfectly refined, as late samples do not seem to be, its use in these pastes is often followed by a rash of a pseudo-erysipelatous nature on the skin round the wound. This is not due to the iodoform, as may be proved by leaving the latter out.

In some cases this rash spreads all over the body. I have had several cases lately in which the internal use of paraffin has been followed by a similar rash—particularly one striking case, in which the patient had been using paraffin harmlessly for years until the last few weeks, when she evidently struck on an impure sample.—I am, etc.,

Highbridge, Somerset, Nov. 27th.

NESBITT BURNS, M.D.

Universities and Colleges.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have been approved in the subjects indicated:

SURGERY.—†C. W. Bower, *†R. H. Chadwick, *†I. Harding, †S. Mikhail, *D. Mintzman, †S. G. Mohamed, †K. S. Vine.

MEDICINE.—†J. Behesnilian, †C. W. Bower, †C. G. Bunn, *D. A. Dyer, *†I. Harding, †S. C. Ho, *†D. Mintzman, *†T. F. Reason, †K. S. Vine.

FORENSIC MEDICINE.—J. Behesnilian, I. Harding, M. Ibrahim, S. Mikhail, J. E. Nicole, T. F. Reason, G. E. Spero, K. S. Vine, MIDWIFERY.—L. E. Lewis, D. Mintzman, J. E. Nicole, K. S. Vine.

* Section I.

† Section II.

The diploma of the society was granted to Messrs. C. W. Bower, R. H. Chadwick, S. Mikhail, S. G. Mohamed, T. F. Reason, and K. S. Vine.

Obituary.

THE RIGHT HON. SIR L. S. JAMESON, Bt., C.B.,
M.D.LOND.

SIR LEANDER STARR JAMESON died at his house in London on November 26th, in his 65th year. He and M. Clemenceau were the two most striking figures contributed by medicine to politics in this age. Both were general practitioners in their early days; both in early middle life took to politics on very stormy seas. Jameson was for four years Prime Minister of Cape Colony, and Clemenceau is just commencing his second term of office and fourth year as Prime Minister of France.

Jameson was the son of an Edinburgh Writer to the Signet, but the family removed to London, and he received his medical education at University College, London. He was a typical specimen of the student who never seems to work but gets through his examinations punctually, and often with distinction. Probably he never read very much and learnt the medicine and surgery he knew in the best school—the out-patient room and the wards. However he got his knowledge, he was a very competent practitioner, and gave his contemporaries the impression that he could become quickly proficient in any subject to which he chose to give his attention. He took the diploma of M.R.C.S. in 1875, graduated M.B., B.S.Lond. in the same year, and M.D. in 1877. After holding the office of house-surgeon he became resident medical officer of University College Hospital. His tenure of this office was interrupted by illness, and later by a visit of many months to the United States with a patient. It was no great surprise to those who knew his adventurous, energetic, and ambitious temperament that on his return he accepted an offer to go into a practice in Kimberley. There he was eminently successful as a practitioner, and became the fast friend of Cecil Rhodes. In 1889, in response to an appeal from Rhodes, Jameson threw up his practice and went on a mission to Lobengula, the Matabele chief, who respected him for his medical skill. Jameson was successful, the Chartered Company was founded, and he went with the pioneers of 1890, but not in an official capacity. In the following year he became Administrator of Rhodesia, and had to encounter difficulties of all sorts—disease, scarcity of food and water, and disaffection among the pioneers. He succeeded in overcoming these, but in 1893 had to face a rising of the Matabele. This he quelled, and established British administration on a firmer and wider basis. In 1894 he was in England with Rhodes; in the following year he went back to South Africa, and became the most ardent champion of the political rights of the new settlers—the Uitlanders—who had flocked to the Rand. In December, 1895, he led the raid into the Transvaal. However his motives may be judged, it was no prudent enterprise, but prudence was not one of Jameson's qualities. The raid failed miserably; he surrendered with a small force to the Boers on January 2nd, 1896, was tried in London in the following May, and sentenced to ten months' imprisonment; owing to the state of his health he was released in December and soon went back to Cape Colony. He served in the South African war in 1899–1900, and in the latter year entered the Cape Legislative Assembly as member for Kimberley. Rhodes died in 1902, and before the general election of 1904 Jameson had become the recognized leader of the Progressive party; that election yielded that party a small majority, and Jameson became Prime Minister. His administration was marked by great financial reforms, by a vigorous policy of railway extension and agricultural development, and by an Education Act, but the great feature and merit of his administration was the pressing forward of the movement for the consolidation of the British States of South Africa in a national union. A Customs conference at Pietermaritzburg in 1906 confirmed the fiscal union, and in 1907 Jameson attended the Imperial Conference in London. Jameson extended the franchise, and one result of the bitter feeling the war had left was that his Government was defeated at the general election of 1908. In opposition he continued to work for the consolidation of the South African union. He sat again in the Cape Parliament from 1910 to 1912 as the leader of the Unionist Party, the policy of which had been settled at the Bloemfontein

Conference in 1910. In March, 1912, illness forced him to resign the leadership of the party, and afterwards he lived mostly in England, occupying himself especially in the work of the Chartered Company and the progress of Rhodesia. He had become a director of the De Beers Company in 1900 and of the British South Africa Company in 1902; in 1903 he became the president of that remarkable company, which has added great provinces to the British Empire, and retained the office till his death. He received the C.B. in 1894, when administrator of Rhodesia, was created a Privy Councillor in 1907, and a baronet in 1911.

This is a very brief sketch of an astonishing career. It seems impossible that any one should make such a career again. There are no more empty continents left. He made one gigantic blunder in supposing that he could do with a handful of men that which it took all the resources of the British Empire and years of hard fighting to accomplish. He was rancorously assailed by politicians, who hoped to use his failure to further their own party purposes; but in the darkest days his integrity and patriotism commanded the respect of his enemies, and he never lost the affection of his friends.

A memorial service will be held at St. Margaret's, Westminster, on Wednesday next at 12.30 p.m. It is intended that the remains shall eventually rest at Matopos, beside those of Cecil Rhodes.

We regret to announce the death of Dr. ELSIE INGLIS, on November 26th, at Newcastle, shortly after landing on her return from Russia. Dr. Inglis was the organizer and leading spirit of the Scottish Women's Hospital Units, which have been established and maintained in France, Serbia, Corsica, Salonica, Rumania, and Russia. Elsie Maud Inglis was the second daughter of the late J. F. Inglis, Chief Commissioner at Lucknow. She studied medicine in Paris, Edinburgh, and Glasgow, and took the diplomas of L.R.C.P. and S. Edin. and L.R.F.P.S. in 1892. In 1899 she graduated M.B., C.M. Edin. She served as surgeon to the Edinburgh Hospital* and Dispensary for Women and Children, and lecturer on gynaecology in the school of medicine of the Royal Colleges, Edinburgh. On the outbreak of war Dr. Inglis proceeded to organize a medical service of women. The Scottish Women's Hospital Units, staffed entirely by women, having been refused by the War Office, offered their services to various allied Governments. During the first months of the war Dr. Inglis and her staff worked at Royanmont. In April, 1915, she went to Serbia to act as Commissioner to the Scottish Women's Hospital established there. The greatest hardships were heroically overcome, and in recognition of her splendid services, notably in dealing with an outbreak of typhus, she received the Serbian Order of the White Eagle, 5th Class, as announced in our columns of April 22nd, 1916. Through the Serbian retreat the party remained to care for the wounded during the enemy occupation of Krushevatz. Subsequently the hospital was evacuated and the staff sent as prisoners to Vienna, being eventually released through the intervention of the American Embassy. In September, 1916, Dr. Inglis took out a new field medical unit of seventy-five women, which was attached to the Serbian Division of the Russian army, and did fine work through the Dobrudja campaign. The unit subsequently worked for nine months at Reni on the Russo-Rumanian front, and on November 24th they arrived in England. Dr. Inglis's health, which had held up through indescribable hardships, gave way soon after reaching port. She was a born leader, entirely patriotic, and free from self-seeking.

LIEUT.-COLONEL HENRY AUGUSTUS FITZROY NAILER, Madras Medical Service (retired), died at Bedford on October 12th. He was educated at the universities of Madras (where he graduated M.B. in 1874) and of Edinburgh, taking the diplomas of L.R.C.S. and L.R.C.P. Edin. in 1875. He entered the I.M.S. as surgeon on March 31st, 1877, became surgeon-major on March 31st, 1879, surgeon-lieutenant-colonel on March 31st, 1897, and retired on October 20th, 1903.

Medical News.

DR. SIDNEY REGINALD DYER, P.M.O. H.M. Prison, Brixton, has been appointed medical inspector of prisons for England and Wales.

DR. ARTHUR HENRY NORRIS, medical inspector since May, 1914, has been appointed by the Home Secretary to succeed the late Mr. C. E. B. Russell as chief inspector of reformatory and industrial schools.

At a meeting of the Harveian Society of London to be held at the St. Mary's Hospital Medical School on December 13th at 5.30 p.m., a discussion on neurasthenia will be opened by Dr. F. W. Mott, F.R.S.

THE report of the Medical Research Committee for the year ending September 30th, 1917, states that its income was diminished by £7,000. As its income is made up of one penny for each insured person, it would seem that there were 1,680,000 fewer insured persons.

SURGEON-GENERAL T. M. CORKER, C.B., M.D., A.M.S., Lieut.-Colonels J. C. Cottell, R.A.M.C., and C. K. Morgan, C.M.G., R.A.M.C., and Major J. Fitzgerald Martin, C.M.G., R.A.M.C., have been appointed Knights of the Grace of St. John of Jerusalem.

DURING December the Camera Club (17, John Street, Adelphi, W.C.2) is showing an exhibition of black-and-white drawings of ward life by patients and staff of the 3rd London General Hospital. Admission, between 11 a.m. and 5 p.m., is free; tickets can be obtained from any member of the club, or on application to the honorary secretary.

At a meeting of the Zoological Society of London on November 20th Mr. R. I. Pocock, F.R.S., F.Z.S., curator of mammals, exhibited the head of a castrated bushbuck (*Tragelaphus*) which had lived several years in the Zoological Gardens at Clifton, to show the effects of the operation on the horns. The horns differed from those of a normal bushbuck in being slender, subcylindrical, untwisted, unkeeled, with a backward curvature like that of the horns of a goral or serow.

THE West Midland Joint Disablement Committee, formed under the scheme of the Ministry of Pensions, provides for three medical representatives being elected by the profession in the five counties constituting the area of the joint committee. The following have been elected: Dr. T. Ridley Bailey (Staffordshire and Shropshire), Dr. Evans (Worcestershire and Herefordshire), Mr. W. F. Haslam (Warwickshire and Birmingham). Dr. Ridley Bailey was also appointed a member of the Executive Committee and chairman of the Treatment Subcommittee.

THE doctors of Wimbledon and district have unanimously agreed: "That, owing to the increased cost of living and the still greater increase in the cost of conducting medical practices, there shall be a general increase in the fees charged for professional attendance and consultations; such increase to be subject to variation or remission in individual cases where some good reason is shown." When messages arrive after a doctor has left home, and these entail inconvenience to other patients by compelling doctors to postpone or break appointments, it has been agreed to charge an extra fee for the special visit.

IN a paper read before the Southern Association of Gas Engineers and Managers, Mr. John West, M.Inst.C.E., gave the results of recent experiments in the carbonizing of coal in which he had co-operated. The application of such methods would, it was calculated, bring about a general increase of from 20 to 25 per cent. in the make of gas per ton of coal carbonized. This would mean a corresponding reduction of the amount of coal necessary, a saving of plant and labour, and a reduction of cost to the public. He urged the necessity of fixing a calorific power standard, and said that the great aim of all gas engineers should be to make and sell gas as cheaply as possible so that the public might be encouraged to use it more extensively for all purposes. It had been calculated that if the 100,000 tons of coal used in Southport for domestic purposes were carbonized, 5,500 tons of tar, 1,000 tons of ammonia sulphate, and 600 tons of high explosive products could be saved, and crude material obtained for the manufacture of dyes and drugs.

ON November 28th a meeting was held at Lady Wantage's house, 2, Carlton Gardens, to discuss the progress of the work of Queen Mary's Convalescent Auxiliary Hospitals, Rehampton, and to promote the establishment of a permanent institution for limbless sailors and soldiers. Lieut.-General Sir Francis Lloyd, chairman of the committee, presided, and spoke warmly in support of the proposal to

raise a fund of £100,000. The object of the fund will be to extend the accommodation for limbless men whilst they are waiting to have artificial limbs fitted, and to put the hospitals on a permanent basis for the future, so that the necessary repairs, replacements, and refittings may be continuously undertaken. There is accommodation at present for 600 officers and men, but the hospitals are always full, and there is a long waiting list. It is hoped to raise the number of beds to 1,000. An indication of the work already done at Roehampton is given by the following round figures: 11,500 officers and men have been fitted with artificial limbs; 2,200 men have been placed in permanent employment; and 6,400 have been passed on to local pension committees or restored to their old employment. Sir Francis Lloyd's appeal for funds was endorsed by the Right Hon. Walter Long in an eloquent speech.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are:

1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Antiloggy, Westrand, London*; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

EDWARDS'S LITHOTOMY SEARCHER.

LITHOTOMY asks for information about a lithotomy searcher presented to the Museum of the Royal College of Surgeons of England in 1871 by its inventor, Dr. G. Edwards, who practised for many years in Cheltenham and died in November, 1886. It is made of nickel-plated steel, is over a foot in length measured by the curve, and is of the calibre of a No. 8 catheter, English scale. The dealer's name is "Weiss, London," but this firm has not now any record of it.

LETTERS, NOTES, ETC.

TRANSFUSION OF WHOLE BLOOD.

IN the article on the transfusion of whole blood, published in the *JOURNAL* of last week, p. 695, the citrate method was inadvertently attributed to Kimpton. The citrate method, as used in the transfusion of blood in man, was designed in the winter of 1914-15, the earliest writers on the subject being Hustin of Brussels and Lewisohn and Weil in America. A modification of the apparatus used recently, devised by Mason and Rivers, was described in the *Journal of the American Medical Association* in June, 1917, p. 1677. Kimpton's method consisted in the application of paraffin to the inner surface of the cylinder.

"COLLOSOL COCAINE."

THE SECRETARY, Medical Research Committee, writes as follows with reference to a letter published last week:

On page 710 of your issue of November 24th you publish a statement from the firm of Crookes Collosols, Ltd., with reference to the above preparation, in which it is said that they have "recently had the advantage of having collosol cocaine tested by Dr. Dale, of the Medical Research Committee." It is important that this statement should not be misunderstood as indicating that the Medical Research Committee, or any members of their staff, undertake the examination of proprietary remedies at the request of the makers.

Dr. Dale and his colleagues undertook an investigation of collosol cocaine on account of the scientific interest of the properties which earlier statements had attributed to the preparation, and the practical importance which the matter would have under present conditions if those statements had been correct. The manufacturers were asked to furnish samples for investigation, and complied with the request. At a later stage further samples were submitted to the Medical Research Committee by a Government department with a request for an opinion on the claims made for the preparation. These samples were examined with the others.

Having failed completely to substantiate the claims made for collosol cocaine, but having every reason to believe that the manufacturers had been simply mistaken in their statements, Dr. Dale gave them a general indication of his conclusions, and advised them in their own interest to withdraw this preparation from their list. This communication was of a verbal and confidential nature, and gave Crookes Collosols, Limited, no authority to use Dr. Dale's name or to publish their own statement in such a manner that any part of it could even mistakenly be attributed to him. Those who are interested in knowing the true nature of the findings concerning collosol cocaine by the Committee's Department of Biochemistry and Pharmacology may be referred to a short article by Drs. Barger and Dale and Miss Durham, which is appearing in the next issue of your contemporary the *Lancet* (December 1st).

CEREBRO-SPINAL FEVER AND ITS TREATMENT.

DR. C. ALWYN STEWART, A.A.M.C. (Weymouth), writes in answer to Captain A. M. Watts (October 13th, p. 502): The serum I used was a polyvalent antimeningococcal serum prepared by Dr. R. J. Bull at the Melbourne University. Captain Watts has evidently confused the dosage of the serum when used intravenously and subcutaneously with that when used intrathecally. Large doses are required in the two former—from 25 to 30 c.cm. is the dose I give in the last instance—the same as that of the Lister or Rockefeller Institute. The reason for excluding cases over 35 years of age and hopeless cases in the corrected column was to secure a uniform comparison, as one group of cases would contain a larger percentage of these and so obscure the value of the treatment. The mortality of the disease is, in my experience, exactly doubled in cases 35 years of age and over compared with cases between the ages of 12 and 35. I define a hopeless case as regards treatment as one that dies within two or three hours of admission to hospital, one that is obviously moribund, or a deeply unconscious patient with a marked purpuric rash—these last never recover, in my experience. I consider a mild case to be one in which there is little vomiting, no rash, no loss of consciousness, and no development of delirium. I may also add that I abandoned lumbar puncture only as a form of treatment very early in 1916, and only gave the figures for completeness and comparison. I consider a severe case to be one in which the initial vomiting is severe, repeated and of a marked toxic nature, in which there is a marked rash and in which there is not a high initial temperature. The foregoing remarks also answer most of the observations made by Dr. Pringle (*BRITISH MEDICAL JOURNAL*, November 17th, p. 671). My "ingenious" statistical method was devised after much thought to obtain a uniform comparison amongst my own cases, not to put to shame the figures of other observers. With regard to the apparent anomaly of mild cases resulting in death, may I explain that the term is intended to indicate the condition of the patient during the early stages of treatment, and the fact of death occurring in some of these cases is an argument for the inadequacy of the treatment indicated. I agree with Dr. Pringle that no "mild" case should die.

DELIVERY OBSTRUCTED BY PRESENCE OF HYMEN.

M.R.C.S., L.R.C.P., writes: A young woman, married just over nine months, was attended by me at her confinement. A cribriform hymen was present, occluding the whole outlet except in three places. Below the orifice of the urethra a small foramen was present, in the centre of hymen another foramen, and at a distance of half an inch from the posterior wall of the vagina a third. The upper two were not more than a quarter of an inch in diameter; the lowest orifice was big enough to admit the tip of the finger, but only then with difficulty. The hymen was thick, but not hard or fibrous. Before delivery I had to make extensive incisions in the membrane. A case like this makes one think that the value of judging the chastity of a woman by the presence of a hymen is small. In the same week I examined a highly neurotic childless woman who had been married seven years, and found a similar hymen present about one inch and a quarter in depth at its greatest measurement. The husband had never experienced any difficulty, but the woman had certainly got very much worse as regards her neurotic troubles since marriage. In the first case the cribriform hymen seems to have suggested to the husband that she should see a doctor, but she did not. The husband is a strong healthy young man and his wife exceptionally strong and healthy.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post restante* letters addressed either in initials or numbers.

A CONTRIBUTION TO THE STUDY OF WAR NEPHRITIS.

[With Special Plates.]

BY

CAPTAIN J. SHAW DUNN, M.A., M.D., R.A.M.C.,

AND

CAPTAIN J. W. MCNEE, M.D., R.A.M.C.

(A Report to the Medical Research Committee from a Mobile
Laboratory in France.)

INTRODUCTION.

A study of the cases of acute nephritis met with in our troops in France has been made, from different points of view, since the beginning of 1916. Since then, by the kindness of the authorities, we have been provided with all the returns and records relating to nephritis in one of the armies, and every facility has been given with regard to particular lines of investigation in units along the front.

The work having been carried out entirely in the zone of an army, it follows that all the cases seen in field ambulances and casualty clearing stations have been men from the trenches or from the area within a few miles behind them. The cases, moreover, have all been observed at an early stage, often within a day or two of the onset of symptoms. With nephritis as met with in men who have never been beyond the base and lines of communication we have had nothing to do.

For military reasons no figures can be given with regard to the extent of the records at our disposal, but the numbers are amply sufficient to enable us to bring forward various general conclusions of interest.

With reference to the types of men involved, infantrymen, who on the front are naturally much in the majority, have provided the bulk of the cases. Artillerymen have, however, suffered severely, and even the personnel of field ambulances, when considered in numerical relation to the other units of a division, have had a fair share. The cavalry, taking them as a whole, must be said to have suffered only slightly, and for reasons made obvious later it may simply be pointed out here that they, owing to the long period of trench warfare, have been much less on the actual front than the other troops mentioned. One point, already referred to by other observers, must be touched on again. This is the comparative immunity of officers, who form barely one-half per cent. of the cases in our records. In passing, the apparently absolute immunity of the native Indian troops in 1915 may be noted, whereas the British troops in these divisions suffered as in others.

Season and locality have, as far as we can judge from the figures, been entirely without influence. Some divisions reached the summit of their nephritis rate in summer, at a time when others close at hand showed a declining incidence of cases. With regard to locality, divisions in our area have shifted ground very freely during the period of observation, whether they still remained in the army or moved into another. These movements have strongly brought out the fact that a division already providing a fair number of cases continues to do so without apparent increase or decrease in the new location. Moreover, a division which up till then has had few cases of nephritis does not show any increase after taking over an area previously held by a division in which the disease was well established.

Severity of weather conditions has had no effect on the returns.

The records of individual battalions and units over a series of months have brought out many points of interest. As regards actual figures, the highest numbers of cases met with in single units are as follows:

Battalions:

- No. 1. Eleven cases in a period of five months.
- No. 2. Ten cases in a period of three and a half months.
- No. 3. Ten cases in a period of four months.

Artillery Brigade:

- No. 1. Eight cases in a period of three months.

In contradistinction to this, other battalions of the same divisions show perhaps only a single case, or even none, during the same period; others, again, have three or four cases of nephritis. In a whole brigade, holding the line

for a period of seven months, only one case occurred, three of the battalions reporting none at all. During the same time the remaining brigades of the division had a fair number of men who suffered from the disease. It has also emerged from the records that whereas a unit may have remained free from nephritis for several months, suddenly, within a very few days, three, four, or even five cases may occur together. A small outbreak of this kind is frequently followed again by a period of freedom from the disease. We consider that the admission to hospital of two or three cases of nephritis from the same unit on the same day has been met with much too often to be explained by coincidence alone.

It has been ascertained by careful inquiry that nephritis does not occur among the civilian population of the army area in any way analogous to its incidence in our troops. Reports from civilian doctors bear this out; and, moreover, in another army zone, where for more than a year a Red Cross unit has been visiting houses in an area full of civilian refugees, including many adult males, and with numerous troops billeted among them and around them, nephritis has not been met with. In this search, undertaken primarily for epidemic disease, many thousands of houses have been visited, right up to a mile or two from the firing line. It seems as if, for the development of the nephritis under discussion, some special circumstances are necessary to which soldiers alone are subjected, and this is in striking contrast to the close relationship commonly maintained as regards epidemic diseases between soldiers and civilians on the front.

CLINICAL OBSERVATIONS.

These will be alluded to only briefly, as accounts of the disease from the clinical side have already been given by Sir John Rose Bradford,¹ Langdon Brown,² and Abercrombie.³

A large number of cases of nephritis, however, have been seen and examined clinically in casualty clearing stations at an earlier stage than was possible for the observers named. It is important to note that a proportion of these, which are of course included in the army records as to numbers, are obviously not primary acute nephritis. For instance, a number of the older men show tortuosity of the brachial arteries at the elbows, and other men give a history of previous attacks of dropsy, etc. Abercrombie also refers to this, stating that in about 25 per cent. of the cases seen by him there was either thickening of the artery at the wrist, or a history of previous renal disease, or both. From a survey of all the cases observed by us, however, a large and very characteristic group can be picked out, and this includes a large proportion of young men previously in perfect health.

It is to this group alone we wish to attract particular attention, as a peculiar "war nephritis," using the term in the restricted sense, and not so as to include chronic cases which date their origin from before the war.

The diagnosis of acute nephritis in this group of men is based on such familiar symptoms as oedema, albuminuria, and breathlessness. These, however, form a peculiar combination which, qualitatively and quantitatively, seems to us to differ from the classical picture of acute nephritis seen in civil life. These symptoms, along with some others of lesser prominence, will be entered into in some detail.

Respiratory Symptoms.

Dyspnoea appears to be a quite unusually prominent symptom. It is, in the great majority of cases, the most outstanding complaint, and is almost always present on admission of the patient to hospital. Very often, as is shown in the accompanying table (Table I), it is the first and earliest symptom to appear, and in two cases only, out of the many examined, was no history or evidence of breathlessness obtained.

TABLE I.—Initial Symptom of the Disease.

Total cases examined, 51.	
Breathlessness	34
Swelling of the face or legs	7
Pain in the head, epigastrium, or back	6
Sore throat	3
Cough and hoarseness	1

In association with the dyspnoea, cough is frequently present, and in some instances this is accompanied by tenacious expectoration. Even although cough is absent

and always in its presence, auscultation of the chest reveals the presence of rales and rhonchi; the physical signs, however, are often slight in comparison with the degree of breathlessness. In only one case was considerable effusion into the chest discovered.

Hoarseness (from laryngitis) was the initial complaint of one man, and sore throat of three others. In the latter cases, apart from some faucial redness, nothing could be seen amiss.

At the time of writing (February, 1917), during a period of intensely cold weather, we have been much struck by the increased severity of respiratory complications. Frequently, indeed, cases are admitted with a diagnosis of bronchitis or bronchopneumonia, which only prove to be nephritis on closer examination. These serious pulmonary conditions, no doubt, account for an increased death-rate from the disease at the present time.

Oedema.

Oedema, while generally present, is frequently confined to the face alone. In many cases, however, it is also present in the legs, and a few examples of general anasarca have been met with. Definite ascites was seen only once. Unless the face is absolutely puffed out by oedema, the cheeks are often well coloured, and certainly in this group of acute cases pallor is not the rule. The general aspect of fair health in the presence of great breathlessness and high albuminuria is indeed often very remarkable.

Pain: Vomiting.

Pains in the limbs and back and headache are frequently complained of, and may be the initial symptoms which lead the man to report sick.

A history of vomiting is sometimes given, but this occurred always at a period antecedent to admission to hospital. In one case vomiting continued for three days, but as a rule ceased after one or two short attacks.

Fever.

Fever was present in six cases only. The temperatures of these on admission, with the approximate duration of symptoms, are shown in the table.

TABLE II.

	Day of Illness.	Temperature on Admission.
Private T.	7	102 F.
Private B.	5	103 F.
Private O.	42	102.4 F.
Private M.	2	104.1 F.
Private S.	7	103.4 F.
Private Mk.	9	■ F., rising to 102.2 F.

In relation to this it must be pointed out that numerous other cases, just as acute and seen at just as early stages of the disease, were completely afebrile. It thus seems as if, during the initial period of symptoms, pyrexia is not a common or essential feature in the clinical picture. Three of the cases shown in the table were noteworthy from the amount of blood passed in the urine, and this will be referred to again later on.

Uraemia.

Uraemia ensued in four of the cases under our direct observation. In one man this led to a fatal result, and a post-mortem examination was made by us. The other three cases recovered rapidly under appropriate treatment and were evacuated to the base.

The Urine.

The urine, when the patient is first seen, generally contains a large amount of albumin. The amount was estimated by the simple Esbach apparatus in thirty-eight cases, with the results shown in Table III. At the same time the amount of urine passed may be little, if at all,

TABLE III.—Amount of Albumin.
Cases examined, 38.

Over 8 ...	3
5 to 8 ...	12
1 to 4 ...	18
Below 1 ...	5

diminished; one case dying of uraemia passed 52 oz. of highly albuminous urine in twelve hours. An important point to draw attention to is that in the first few days after admission to hospital the amount of albumin frequently undergoes a rapid diminution, and may be almost absent at the end of a week. This is well shown in the accompanying table, which also illustrates how little the urinary output may be diminished. In some cases, how-

TABLE IV.

(Pte. B., aged 26 years; ill five days.)

Date.	Albumin in Parts per 1,000.	Quantity of Urine in 24 Hours.
May 15th, 1916 ...	7	28 oz. (in 12 hrs.)
" 16th ...	3	48 oz.
" 17th ...	1	45 oz.
" 18th ...	1	42 oz.
" 19th ...	1	45 oz.
" 20th ...	1	52 oz.
" 21st ...	Less than 1	57 oz.
" 22nd ...	Less than 1	57 oz.

ever, the amount of albumin remains consistently high during the few days before evacuation to the base. Even when the quantity of albumin is large, the presence of blood may not be recognizable to the naked eye. We have been much struck, in the course of our observations, with the number of samples of urine examined which, while loaded with albumin, were still pale and perfectly clear. In the centrifugalized sediment some blood corpuscles and leucocytes are to be found in every case. In a few instances copious haematuria has been met with, and these men have all presented certain features in common which are of interest. All had pyrexia on admission, and none had a very high percentage of albumin (often not more than might be accounted for by the bleeding alone). In one case bleeding was so copious that, from the appearance of the urine sent for examination, a suspicion of calculus or tubercle arose, until it was found that the patient had marked breathlessness, oedema of the face, and a systolic blood pressure of 150 mm.

Casts are always present in the centrifugalized sediment, but are often far from numerous. The chief varieties met with are:

1. Hyaline casts.
2. Hyaline casts each containing a few intact cells from the renal tubules.
3. Casts which may be described as partly granular, partly epithelial.

Of these the second type is so frequently seen as to attract rather special attention.

Careful bacteriological examination of catheter specimens of urine from thirty-five cases was made (Table V).

Streptococci were found fairly frequently, of a type growing luxuriantly on ordinary media, and never pathogenic to animals. Similar cocci were, however, also found in control catheter specimens from patients not suffering from nephritis. No importance can be attached to them, and the table of results only shows how difficult it is to attain complete asepsis in specimens of urine taken with the greatest care.

TABLE V.—Bacteriological Examination of Catheter Specimens of Urine.

Sterile ...	14
Streptococcus (pure) ...	12
Streptococcus (impure) ...	3
Various other contaminations (<i>B. coli</i> , <i>Staphylococcus aureus</i> , diphtheroids, etc.) ...	6

Forty acute cases have been examined by blood culture, ordinary media being used for half of these, and Thornley's special pea-extract broth for the remainder. All the cultures remained sterile, even after prolonged incubation.

CLINICAL SUMMARY.

In concluding the clinical account we would suggest that the high albuminuria, often without obvious blood, the absence of oliguria, the frequent rapid decrease in the amount of albumin, the predominant dyspnoea, and the

general healthy appearance of the patient while obvious signs of nephritis are present, give collectively a rather characteristic picture, differing from that of the average case of acute nephritis at home.

PATHOLOGICAL OBSERVATIONS.

The following account of the pathology of the condition is based on the examination of tissues from forty-two cases in which a diagnosis of acute nephritis had been made during life. As the death-rate is low we have been indebted to numerous officers with the armies and at base hospitals for the supply of such a large amount of material; in only two instances have we had the opportunity of performing the *post-mortem* examinations. The known duration of illness in these fatal cases is remarkably brief, the longest being about a fortnight, while the shortest is less than forty-eight hours.

Four of the cases need be referred to only briefly, as the changes present are obviously not those of primary acute nephritis. In two of these the kidneys are granular and atrophic, and in a third there is subacute nephritis with amyloid degeneration. The fourth is a febrile jaundice, with haemorrhagic nephritis, probably a case of Weil's disease. In three cases no definite evidence of nephritis is found in the kidneys, although the clinical histories point to that condition. The relation of such cases to others where there are obvious lesions is uncertain, and requires further investigation.

The remainder of the cases, thirty-five in number, exhibit striking uniformity in their important pathological features. The variations in detail which they present may depend on differences in the duration of the disease. Only two kidneys merit separate description, as they show subacute characters. In the remainder the appearances are quite in keeping with the diagnosis of acute nephritis, and the existence of an old-standing lesion can be excluded. In view of the large number of kidneys examined and the concordance of the results, it seems safe to regard the histological changes which will be described as representative of the renal condition in the war nephritis under discussion.

THE RENAL LESIONS.

The changes which can be observed by the naked eye are very slight. Some of the kidneys are slightly enlarged, but most are of normal size. The capsules are non-adherent, and the surfaces are smooth. The cortex is generally pale, and the medullary pyramids rather congested. Under a hand lens one feature can generally be recognized, which we have come to regard as characteristic: the glomeruli are seen to project from a cut surface as pale translucent globules, in contrast with their normal red appearance.

On histological examination the most prominent abnormality in all cases is found in the glomeruli. These appear, on low power examination, to be somewhat enlarged and more cellular than normal, while they contain little or no blood (Fig. I). In many instances a rounded projection extends from a swollen glomerulus into the opening of the convoluted tubule. The details of the glomerular changes can be made out only by the aid of special staining, and on close examination with an oil-immersion lens, but as they appear to be of cardinal importance they will be fully described.

Many of the capillary loops forming the tuft have their lumina dilated, and contain numerous nucleated cells, but few or no red blood corpuscles (Fig. II). These cells have oval or flattened nuclei, like those of endothelia, and fairly abundant protoplasm, which frequently shows a very indefinite margin. Where they are numerous and closely packed together they resemble a syncytium (Fig. VII). In several of the cases mitotic division is observed in a few of the nuclei, but long search for this feature in the others has yielded a negative result. Granules of fat are occasionally present in the protoplasm, and fatty change is sometimes very marked in the cells occupying loops of capillaries which project into the mouth of a tubule. Polymorphonuclear leucocytes and lymphocytes accompany the endothelial cells in the lumina of the capillaries in varying numbers, but they are never very abundant. Search has been made for hyaline thrombi in the same situation, but with negative result. In many of the kidneys, especially where the disease has been rapidly fatal, the accumulation of abnormal cells in the glomerular capillaries is very marked and widespread, so that in any

section of a tuft not more than one or two loops contain red corpuscles and have a normal lining. The degree of blockage is less pronounced on the whole in cases of older standing. In view of the considerable vascular disturbance which must ensue from occlusion of capillaries, it is remarkable that exudative phenomena are almost entirely absent, and degenerative changes are only slight. The epithelial cells covering the tufts generally show only slight catarrh; their protoplasm is thickened and of degenerate appearance, while discarded cells, which are sometimes caught around the projection in a tubule mouth, may exhibit fatty degeneration. Crescent-shaped accumulations of cells in the capsule are seen only in one case, and are there very scanty. There is no exudate of fibrin or leucocytes inside or around the capsules, and intracapsular haemorrhage is rarely seen. The tufts show no appearance of patchy fibrosis or of adhesion to the capsules, such as occur so commonly in glomerular nephritis. The greatest degree of degenerative change is limited, as a rule, to some hyaline thickening of capillary walls, and of the fibrous tissue of Bowman's capsule. The capillary blood vessels in the cortical labyrinth and in the medulla show no change comparable to that found in the glomeruli.

An additional form of lesion, which is probably of considerable significance, has been observed so far in only three cases, and in these only rarely. This is a condition of total infarction of certain glomeruli. The capillaries in these are dilated and engorged with red blood corpuscles, and excess of endothelium is present only in a few loops. These glomeruli exhibit catarrh and hernial protrusion like the others. In serial sections it is determined that the infarction is due to the presence of hyaline material in the afferent arteriole, and in some instances the wall of this vessel shows evidence of necrosis and slight leucocytic invasion. No micro-organisms are recognizable in the hyaline material, or in the glomeruli generally, by any staining method.

The conditions in the convoluted tubules show less uniformity, and in most cases are much less easy to estimate. The renal epithelium so quickly develops autolytic change that no absolute reliance can be placed on the appearance of breaking down of cell protoplasm, unless it is known that the tissue has been suitably fixed very soon after death. In some of the cases, however, there is certain evidence of catarrh; thus, in addition to fragmentation of protoplasm and loss of nuclei, some cells show well-marked fatty degeneration, while in others the nuclei exhibit various stages of karyokinetic division (Fig. III). Even where these phenomena are noted there is seldom much desquamation of whole cells, and never any loss of all the cells from one section of a tubule. The epithelial casts, which are rarely seen in lower segments of tubules, are evidently made up by agglomerations of cells which have desquamated separately.

Tubular haemorrhage is present to some extent in every case, but is not abundant, and is sometimes found only with difficulty. It is seen either in the first convoluted tubules, in which case the blood is fresh and the blood corpuscles are well preserved and lie free, or else in the ascending limb of Henle's loop in the form of a brown-coloured cast, with the corpuscles packed together, lysed, and misshapen.

In most of the kidneys there are some long hyaline casts in the upper part of the ascending limb of Henle's loop, and especially in the junctional tubules leading from these. In three of the cases, in which the known duration of the disease was from six to fourteen days, these hyaline casts are very numerous and elongated, and in a considerable number of them the upper or peripheral end contains calcified debris in the form of granules or small concretions. The calcified material occurs most frequently and characteristically in the junctional tubule, which winds round the arterioles of the glomerulus from which that tubule has originated (Fig. IV).

The interstitial connective tissue of these kidneys is, on the whole, of the delicate consistence seen in the normal organ. In all of them there are present some sclerosed glomeruli, with accompanying patches of slight fibrosis of the interstitial tissue of the cortex, but these are not more numerous than may be found in the kidneys of healthy men of military age who have died of wounds. They are evidently of no significance for the existing acute disease.

Brief reference may be made to an alteration which is

not infrequently observed in the medullary pyramids: this is a condition of oedema and hyaline swelling of the connective tissue fibres which surround and support the groups of straight arterioles. The descending limbs of Henle's loops, which are embedded in the same tissue, sometimes contain dense hyaline material, staining strongly with eosin; occasionally this is accompanied by leucocytes. The significance of these appearances is unknown, and they require further investigation.

In the two cases in which the lesion is described as sub-acute there is a general almost uniform overgrowth of the supporting connective tissue of the kidneys. The tubules show some lowering of type of the secretory cells, but there is not much atrophy of whole tubules. Fatty degeneration of epithelium is well marked. In one case the glomeruli present a rather slight degree of the changes described in the acute cases, and there is in addition very abundant tubular haemorrhage. In the other, which is more advanced, the glomeruli are much enlarged and exhibit, in addition to proliferation of capillary endothelium, much fibrosis in their substance and fibrous thickening of capillary walls. The afferent arterioles are here invariably much dilated and the efferent ones collapsed, indicating the prolonged existence of obstruction to the circulation of the tufts. The pathological condition is such as might be expected to arise in these structures as a sequel to the changes described in the acute disease.

LESIONS IN OTHER ORGANS.

The discussion of changes which have been met with in the other organs will best be introduced by a short account of an acute case ending fatally, in which we were enabled to carry out a complete *post-mortem* examination very soon after death.

CASE 11.

The patient, aged 33 years, died after an illness of nine days' duration, characterized by oedema, cough, dyspnoea, headache, and albuminuria, with gradual development of blindness and unconsciousness.

The kidneys, on naked eye examination, were large and firm. The capsules stripped easily and the surfaces were smooth. The cut surface showed pallor of the cortex and congestion of the pyramids. On histological examination the changes in the glomeruli were found to be the same as those described in the general statement, but not of extreme degree. Calcified casts were present in many of the junctional tubules, and tubular haemorrhage was not infrequent. Apart from these the tubular changes were slight.

The lungs presented very striking appearances on naked eye examination. They were very voluminous, heavy with oedema, and showed extensive acute emphysema. Much frothy fluid welled out from a cut surface, of neutral reaction to litmus. Some slight diffuse haemorrhages were visible beneath the pleurae, and also in the deeper substance of the lungs on section. On histological examination the conditions of oedema and acute emphysema were everywhere very marked, and in a few sections from the bases of the lungs lobular consolidation was present. The most remarkable feature, however, was observed in many of the terminal bronchioles and infundibula (Figs. V and VIII). The walls of these cavities were unduly prominent, being swollen by oedema, with some exudation of leucocytes in their substance. The lining epithelium was lost, and the exposed surfaces covered by layers of dense material resembling fibrin. This peculiar form of lesion was distributed abundantly throughout the lungs without special reference to the areas of consolidation. It did not correspond histologically to any usual type of pneumonia or bronchitis, but simulated rather the result of inhalation of an irritant gas. In the larger bronchi the epithelium was practically entirely desquamated, and the exposed basement membrane covered in places by adherent fibrin; leucocytic reaction was here remarkably slight. In addition to the damage of mucous surfaces, a less obvious but noteworthy feature was the presence in many of the alveolar capillaries of minute hyaline thrombi, occurring always in relation to damaged infundibula (Fig. IX).

The brain exhibited numerous minute haemorrhages in the white matter, particularly in the frontal and occipital lobes (Fig. X). These were found to present very striking histological characters, which could only be fully appreciated by the study of continuous serial sections. Each haemorrhage had the form of a small hollow sphere of effused blood corpuscles, with the centre filled by a rounded mass of apparently necrotic brain tissue free from blood. Crossing the centre of this apparently necrosed brain tissue there could be traced, in every instance, a capillary blood vessel filled with normal-looking red corpuscles (Fig. VI). The somewhat paradoxical character of these lesions, which indicated that the blood had become separated from the point at which it left the vessel by an intervening layer of tissue free from blood, presented a histological problem which cannot be fully dealt with at present. It is sufficient to say that it was surmised that military embolism had played a part in their occurrence, and this view received support by the finding of hyaline thrombi in the central vessel of several haemorrhages.

The spleen was enlarged, and weighed 12 oz. Its peritoneal surface presented numerous minute puckers, and tiny shreds of fibrin were adherent over it. On section numerous small haemorrhages were seen scattered throughout the pulp. The origin of these was not definitely ascertained by histological examination.

The liver, on microscopic examination, exhibited some necrosis of cells in the central parts of the lobules around the radicles of the hepatic vein.

It was possible in this case to make a fairly comprehensive bacteriological examination of the various organs. No organisms of any kind were observed in films made from the kidneys, spleen, or liver, nor from pleural, pericardial or peritoneal fluids. Aerobic cultures of these also gave entirely negative results. In films from the bronchial secretions and from the oedematous fluid in the lungs only a few Gram-positive diplococci were observed; on cultivation a limited number of colonies of organisms resembling pneumococci were obtained. The injection of 5 c.cm. of oedematous fluid from the lungs produced no pathological effects in a rabbit. Portions of the various organs were examined for spirochaetes by Levaditi's method, as well as by Giemsa staining, but with negative result. As no unequivocal significance could be attached to the presence of a few pneumococci in the pulmonary tissues, these bacteriological examinations were regarded as essentially negative; they certainly excluded the existence of any ordinary septicaemia.

In view of the condition of the lungs in this case, inquiry was made as to whether there had been any recent exposure to poisonous gas, but no history of this was obtainable. The action of a pulmonary irritant was, however, so strongly suggested by the pathological appearances, as to indicate the importance of searching for similar phenomena whenever opportunity presented. It is now possible to refer briefly to the conditions found in twenty-two other cases from which small portions of various organs have been obtained.

In eight cases the pulmonary tissue which was available for examination showed appearances almost identical with those described above. Thrombosis of capillaries in relation to damaged infundibula was recognized in every case, and in one instance was a very marked feature. In the brain of this particular case there were abundant haemorrhages in the white matter, of the type already referred to. In one case, where the brain contained no haemorrhages, the retina was examined microscopically; it exhibited two minute haemorrhages, one in the ganglionic layer, and the other in the outer vesicular layer.

In another group of cases, also eight in number, the lungs showed lesions, less pronounced, but noteworthy. They may be illustrated by the following example which was typical of the group:

CASE 29.

The glomerular lesion in the kidney was well marked and characteristic. The lungs showed some oedema and emphysema. Many of the infundibula had dilated lumina, and the radiating alveolar walls around them were slightly swollen by oedema; the swelling was most marked in the musculo-elastic tissue at the bulbous inner end of the alveolar partitions. Very frequently these extremities were covered by layers of dense adherent hyaline material, like fibrin. Occasionally the fibrin-like layers were more extensive, and entered the alveolar cavities. Thrombi could be recognized in a number of instances in the capillaries around damaged infundibula. These thrombi were often accompanied by phagocytic cells and appeared to be undergoing absorption. Many of the bronchioles showed evidence of catarrh, while others were practically normal. No haemorrhages were found in the brain.

In three other cases the lungs presented changes of bronchopneumonia, and infundibular lesions of the type described above could not be definitely recognized. In only two instances no definite lesions of any kind were found in the portions of lung examined.

The remaining case in which it was possible to examine the lungs presented some peculiar features.

CASE 4.

Admitted after uraemic convulsions; high fever developed soon afterwards, and a diagnosis of double pneumonia was made; death occurred fourteen days after admission to hospital. The glomerular lesion was similar to the typical one described, but was of older standing, and apparently tending towards recovery. Distinct interstitial proliferation of connective tissue was present in some areas of the kidney, but this did not extend to the organ as a whole. A few glomeruli exhibited a condition of complete infarction, due to closure of the afferent arterioles by hyaline material. The lungs in some

areas exhibited patches of bronchopneumonia, with fibrino-purulent exudate in the alveoli and pus in the bronchioles. The presence of the acute inflammatory lesion rendered it difficult to make an absolute pronouncement regarding the origin of certain additional phenomena, but it was certainly true that in all parts of lung examined, even where there was no consolidation, there was evidence of very extensive recent destruction of alveolar walls. The ends of the walls next the infundibular cavities were most frequently lost, so that these spaces appeared unduly large and rounded. The walls of the alveoli were definitely thickened, and more cellular than usual, and on close examination it was seen that their capillaries contained many detached endothelial cells and leucocytes, while in some areas minute hyaline thrombi were also visible. The condition of this lung in general resembled that which is found from seven to ten days after the inhalation of chlorine.

COMMENTARY.

In considering the pathological features which have been observed in the group of cases submitted to histological examination the lesions in the kidneys have first claim to attention. It has been shown that while both the tubules and the glomeruli exhibit morbid changes, it is those affecting the latter structures which are most constant and distinctive. The most noticeable feature is that the capillary blood vessels of the tufts have their lumina to a greater or less extent obstructed by abnormal cells, and the circulation of blood in them appears to be correspondingly restricted. As it is from these capillaries that the bulk of the urinary fluid is normally excreted, it might be expected that such a condition would inevitably be associated with marked diminution of urinary output. This, however, is not in agreement with our clinical observations, for in the majority of the milder cases which have been specially examined, and even in some which were moribund, there has been little diminution in the amount of urine excreted. Accordingly, the blockage of the capillaries can only be regarded as one indication of the whole extent of damage which they have suffered. The hyaline thickening of capillary walls which is present in some instances is another evidence of deterioration, but it has not always been a recognizable feature. Catarrh of the glomerular epithelium and fatty degeneration, when present, are no doubt dependent for their origin on the primary vascular flaw.

The convoluted tubules exhibit definite evidence of catarrh only in a few instances, so it is evident that gross damage of the highly specialized cortical cells is not an essential factor, even in fatal cases, of this form of nephritis. The tubular haemorrhages, which, though sometimes scanty, are always present, are a further indication of the implication of blood vessels. It is possible that the haemorrhages are derived from the glomeruli, the blood having been carried downwards in the urinary stream.

From the absence of any diffuse overgrowth of interstitial tissue in the acute cases, it is evident that the kidneys have been previously healthy. The stroma is also remarkably free from acute cellular exudation.

The type of glomerular lesion described above, with all its subsidiary details, has already received full recognition in the past, as being characteristic of an early stage of acute glomerular nephritis.⁶ In the present series of cases there is a remarkable absence of definite acute inflammatory changes in the tufts, such as develop so frequently in that disease. Even in the oldest of the acute cases, which must have lasted for more than a fortnight, there is little evidence of tissue destruction of an irretrievably permanent character. The nature of the lesions is, therefore, not suggestive of the local effects of bacteria, and so far no organisms have been observed in relation to them. Bacteriological examinations of the blood in living cases have also yielded negative results.

The etiology of acute glomerular nephritis in general remains to a great extent obscure. Sometimes the disease develops out of a septicaemic condition, such as may occur in pneumonia, or as a sequel to scarlet fever. Even in these cases the exact relation of organisms to the lesions in the glomeruli is not readily ascertainable. In the form of the disease which may accompany chronic ulcerative endocarditis the glomeruli apparently suffer primarily from the deposition of minute emboli, probably infected, in their capillaries. It is quite evident, however, that glomerular nephritis frequently develops in the first place without any condition of septicaemia being recognized or suspected, and regarding the mode of causation of such cases very little

is known. The pathological conditions which we have described in the kidneys afford grounds for some suggestions which, although probably not new, may be considered worthy of attention. The striking feature of the lesions is the almost uniform and universal implication of a particular set of capillary blood vessels—namely, those of the tufts—in both kidneys. This selective incidence might be accounted for theoretically either by the anatomical or by the physiological peculiarities of the glomeruli.

From the point of view of structure the glomerular capillaries are so situated as to receive first, by the afferent arterioles, the great bulk of the blood, which is ultimately, through the efferent vessels, distributed to the cortical labyrinth. Accordingly they are in a position to filter out from the blood stream any particles which are too large to pass through capillaries, and if such a process occurs a specifically glomerular lesion may be expected to result. As has been indicated, this is probably the explanation of the nephritis caused by ulcerative endocarditis, where the arrested particles are infected emboli. It is to be remarked that in this class of case the glomeruli tend to be unevenly affected and to exhibit lesions of markedly focal character. If, in the present diffuse intracapillary form of glomerulitis, the excess of endothelium is to be regarded as embolic in origin, it must presumably be derived from the walls of systemic or pulmonary vessels, damaged by a circulating irritant. From the nature of the problem, evidence in support of such a view is difficult to obtain.

From the point of view of function, the glomerular capillaries are specialized in that they excrete a high percentage of the water and of the saline constituents of the urine. In analogy with this a specific disturbance of their endothelial lining may depend on the presence in the blood of some noxious substance which, from its chemical characters, is suitable for excretion by the same channel. In the process of excretion it will come into more intimate relationship with the cells of the glomerular capillaries than of those in the vessels generally. The extremely uniform involvement of all the glomeruli is more in accord with the latter mode of causation than with that depending on the anatomical factor.

Apart from the conditions in the kidneys, the most striking organic lesions have been observed in the lungs and in the brain of certain cases. Inasmuch as these lesions are characterized by damage of minute blood vessels, they appear worthy of close consideration in relation to the nephritis.

Multiple haemorrhages of a distinctive type have been found in brain in two cases only,⁷ and there is no evidence available to explain why these two are thus distinguished from the others. In both instances there had been cerebral symptoms of coma or delirium, but there was no definite history of convulsions. On the other hand, in several instances where there had been uraemic convulsions no haemorrhage was found in the brain. The lesions are almost entirely confined to the white matter, while the more vascular grey matter remains practically free. This selective distribution, no less than the peculiar characters of the individual haemorrhages, is indicative of some more specific form of causation than would be provided by rise of arterial pressure or slowing of the venous return. Miliary embolism has seemed to us to offer one adequate explanation of the focal damage of capillaries and nervous matter, but it is only in a very few of the haemorrhages that the central vessels are blocked, so that this view lacks full confirmation. Another organ which has occasionally presented miliary haemorrhages is the spleen, but in that tissue the exact origin of the bleeding is impossible to define. Retinal haemorrhages have been observed in one acute case, but unassociated with haemorrhages in the brain.

In view of the predominance of dyspnoea in the clinical aspect of the disease, the pulmonary changes possess a special interest. It has been shown that, in addition to oedema and sometimes bronchopneumonia, there is very frequently injury of tissue around the cavities of pulmonary infundibula. The degree of damage varies, but it is invariably maximal towards the mucous surfaces, and especially on ridges which project inwards. The appearances are strongly indicative of the presence of a

* These have been found subsequently in four other cases.

deleterious agent in the lumina. The lesions are sometimes so strongly developed and so widely distributed that they cannot fail to be noted in any section; in such instances the pathological changes are obviously recent and acute in character. In other lungs the lesions are much less obvious, and appear to be residual and healing, but they are still quite definitely recognizable even in small portions of tissue not specially selected. Like the more acute ones, they may be accompanied by some thrombosis of pulmonary capillaries. The lesions are frequently unassociated with exudation of leucocytes in the alveolar spaces, and no organisms are then observed in relation to them. Where bronchopneumonia is present, organisms can be seen in the consolidated areas, and the infundibular changes in these are masked by the cellular exudate. They are, however, generally recognizable in uncomplicated form in other parts of the lung. Most frequently there is some similar damage of mucous membranes in bronchioles, and even in bronchi of larger sizes, unaccompanied by leucocytic reaction. On grounds which are almost purely anatomical we have assumed that these infundibular changes have been produced by a labile irritant, but as to the actual source of this we have at present no information. It is possible that the irritant in question has been excreted from the blood with the oedematous fluid. On this supposition the pulmonary lesions would be secondary in origin to the nephritis, or else parallel to it, and due to the same common cause. They would still possess considerable pathological significance, for in some instances they are so extensive and severe as to indicate a toxic action of considerable potency.

On the other hand, it has appeared to us possible that the pulmonary lesions may have been caused primarily by a noxious agent inhaled from the atmosphere. For this supposition, which, if correct, would possess great significance, we can find no support from the history of any of the cases. Still, the histological appearances are, in some instances, so suggestive of the effects of a pulmonary irritant, and so similar in many features to the lesions caused by irritant gases, that we have felt compelled to give full consideration to this view. There is, of course, no suggestion that the lesions under discussion are caused by chlorine or by any of the other gases used by the enemy, for it is recognized that clinical nephritis is not a common development after exposure to drift gas. The ascertained anatomical facts, however, in fatal gas poisoning offer a certain support to the view that a renal lesion may be produced as the result of inhalation of a gaseous irritant. Captain Herbert Henry has found that where death occurs late, seven to ten days, after chlorine poisoning, the renal glomeruli may exhibit extensive inflammatory changes, associated with the presence of thrombi in their capillaries. Similarly, three days after poisoning by shell gas (? phosgene) we have ourselves observed numerous thrombi in the renal glomeruli, but unaccompanied at that date by any evidence of inflammatory reaction. Another important point is that miliary brain haemorrhages are of frequent occurrence after

poisoning by phosgene, though apparently after the gas attacks in which chlorine was employed these lesions were not noted. On histological examination these cerebral haemorrhages exhibit the same distinctive characters as those we have observed in two cases of nephritis. The remote vascular lesions in kidney and brain in gas poisoning are associated with primary lesions in the lungs which are characterized by extensive thrombosis of capillaries. The whole forms an anatomical complex very similar in distribution to that which we have described in nephritis; the cerebral haemorrhages in particular are so identical in type as to suggest the existence of some common factor in the two classes of case. Even in gas poisoning the exact mode of production of the systemic lesions has not yet been definitely ascertained, and this point is worthy of further investigation on experimental lines. The information so obtained may by analogy throw light on the process on which nephritis is based.

DESCRIPTION OF SPECIAL PLATES.

CAPTAIN J. SHAW DUNN AND CAPTAIN J. W. MCNEE.

FIG. I.—A glomerulus in acute nephritis, exhibiting slight enlargement, and pointing into the opening of the convoluted tubule. The tuft is excessively cellular, and contains very few red blood corpuscles. Note the absence of inflammatory exudate or adhesions. $\times 125$.

FIG. II.—High-power view of a portion of a glomerulus in acute nephritis, showing accumulation of excess endothelial cells in the lumina of the capillaries. $\times 400$.

FIG. III.—Mitotic division of highly specialized secreting cells in convoluted tubules in a case of acute nephritis. Two karyokinetic figures are visible. $\times 400$.

FIG. IV.—Calcified cast, densely black, in the junctional tubule beside a glomerulus; from a case of acute nephritis. $\times 125$.

FIG. V.—Section of oedematous lung in a case of acute nephritis. Of the two large cavities, one, the more rounded, is a terminal bronchiole; the other, irregularly V-shaped, represents two infundibula. The former shows loss of epithelial lining and deposition of fibrin-like exudate on its walls. In the infundibula fibrin layers are present, especially on the ridges, and give the appearance of a thick wall, which is quite abnormal. $\times 60$.

FIG. VI.—Minute haemorrhage in cerebral white matter, in a case of acute nephritis. The pale area in the centre of the haemorrhage is necrosed nervous tissue. Near the centre of the necrotic focus there is seen the transverse section of a minute blood vessel filled with red corpuscles. $\times 125$.

FIG. VII.—A glomerulus in a case of acute nephritis. The capillary loops contain a great excess of nucleated cells; most of these appear to be swollen endothelial cells, with oval nuclei, and many of them lie free in the lumina. A few endothelial cells are seen in their normal situation, with narrow, darkly-stained nuclei. A few leucocytes are visible, and red corpuscles are very scanty. The afferent arteriole is filled by a syncytial mass of loose protoplasm. Note catarrhal desquamation of epithelium from the portion of the tuft which protrudes into the opening of the convoluted tubule.

FIG. VIII.—An infundibular lesion in the lung in a case of acute nephritis. The walls of the cavity are coated by a thick layer of fibrin-like material, stained dull blue. There is evidence of oedema in the adjacent alveoli.

FIG. IX.—Thrombosis of a pulmonary capillary in a case of acute nephritis. The drawing shows part of an alveolar partition with its bulbous inner end. The thrombus appears as a mass of homogeneous material, stained pink, in contrast with the more orange-coloured red corpuscles.

FIG. X.—Multiple miliary haemorrhages in the brain in a case of acute nephritis. The haemorrhages are scattered throughout the white matter, but are more numerous in some areas than in others. The grey matter of the cortex is practically free. In some of the larger haemorrhages a minute white centre is visible.

CONCLUSIONS.

1. One of the most characteristic clinical features of war nephritis is the early occurrence of dyspnoea, which, though often pronounced, may not be adequately accounted for by any pulmonary condition recognizable from physical signs.

2. The rapidity with which the initial symptoms of the nephritis may subside, after admission of patients to hospital, is remarkable. It is frequently so striking as to suggest that the mere transfer of the patient has brought about discontinuance of the circumstances which caused the disease.

3. From a consideration of the pathological conditions no direct conclusion has been drawn regarding etiology; but some important facts have been ascertained. The visible alteration in the kidneys which is most constant and distinctive is limited to the capillary blood vessels of the glomeruli. The absence of definitely inflammatory reaction in these structures, and the uniformity and selective distribution of the lesions, suggest that they are due to the presence, in the

blood stream, of a mildly irritant agent with a special effect on the smaller blood vessels. The oedema of subcutaneous tissue, and the vascular lesions in the lungs and the brain are probably due to the same factor. The renal glomeruli may suffer especially by virtue of their specific function in excretion. So far no positive evidence has been obtained which would point to organisms as the primary source of the damage of vessels.

4. The minute cerebral haemorrhages which are occasionally present in nephritis are of exactly similar character to those which frequently occur after poisoning by phosgene. They suggest the existence in the two classes of case of a common form of alteration in the circulating blood, which may thus be accessible to experimental investigation.

5. In fatal cases of the nephritis the pulmonary air passages are frequently the seat of lesions which bear some resemblance to those produced by irritant gases. While this comparison may be fallacious as regards the source of the irritant agent in nephritis, it affords a measure of the damage which is found in the lungs in

some instances. These pulmonary lesions probably possess some significance in relation to the frequent occurrence of dyspnoea.

For the supply of clinical records and pathological material we must thank collectively a very large number of officers throughout the armies in France.

We are especially grateful to Surgeon-General W. W. Pike, who placed all the records of cases of neplritis in his army at our disposal, and to Colonel Sir Wilnot Herringham, who has all along taken the greatest interest in the work and given us much valuable assistance and advice.

ON THE HAEMAGGLUTININ REACTION AS A TEST OF THE TOXICITY OF VARIOUS ANTISEPTIC REAGENTS.

AND ON THE ASSOCIATION (IF ANY) BETWEEN THE HAEM-
AGGLUTININ CONTENT OF THE BLOOD SERUM AND
PUS, AND CAPACITY TO RESIST INFECTION.

(With Special Plate.)

BY

C. J. BOND, C.M.G., F.R.C.S., COLONEL A.M.S.,

HONORARY CONSULTING SURGEON, NORTHERN COMMAND; HONORARY
CONSULTING SURGEON TO THE LEICESTER ROYAL INFIRMARY;
MEMBER OF THE MEDICAL RESEARCH COMMITTEE.

It is known that different individuals vary in the capacity of their blood serum to agglutinate the red blood cells of other individuals and of animals of different species. It is supposed that somewhere about 80 to 90 per cent., possibly more, of all individuals possess blood serums containing one or other of the different haemagglutinins. The following inquiry was undertaken to test (by utilizing the agglutination reaction) the toxicity of various antiseptic reagents to the blood serum and the red corpuscles, and to ascertain whether patients whose blood serum contained any of these haemagglutinins resist infection better than patients with non-agglutinating serums.

During a previous investigation into the influence of antiseptics on the activities of leucocytes and the healing of wounds¹ it became necessary to examine the blood serum in order to test the toxicity of different serums to my own leucocytes during incubation. This examination, while revealing facts of interest concerning the action of different serums on the white blood cells, also confirmed the previously known fact of the existence of iso agglutinins in the serums of a considerable number of patients taken from a hospital population. Fortunately several different patients were found possessing blood serums of four distinct haemagglutinative types (Fig. I), namely:

1. A serum agglutinative to human (C. J. B.) red cells but non-agglutinative to sheep's red corpuscles.
2. A serum agglutinative to human (C. J. B.) red cells and also to sheep's red cells.
3. A serum non-agglutinative to human (C. J. B.) and to sheep's red cells.
4. A serum agglutinative to human (C. J. B.), sheep's and guinea-pig's red cells.

Without entering into the wide problem of the relative

The Medical Research Committee have provided us with some of the apparatus necessary for histological work, and we are indebted to them also for permission to use the drawings made by Sergeant A. K. Maxwell, R.A.M.C.

incidence of these different kinds of agglutinative serums in man and in the animal species it is evident that such a sharply defined divergence in agglutinative capacity affords a means (when employed under controlled conditions) of investigating (a) the relative effect of different antiseptic reagents on agglutination, and (b) the value, if any, of the iso-agglutinative factor in the production of acquired immunity against infection.

The Iso-agglutinative Reaction as a Test of Antiseptic Toxicity.

While the bactericidal capacity of an antiseptic reagent is of the greatest significance, it is becoming increasingly evident that the relative toxicity of different reagents to the blood and tissue cells is also a matter of equal importance.

From the theoretical point of view it is desirable to test this toxicity in regard to (a) the white corpuscles, (b) the red corpuscles, (c) the tissue cells, (d) the plasma and the blood serum. I propose, however, in this communication to refer only to the effect of different antiseptics on the capacity of any given blood serum or pus to clump human (my own) washed red corpuscles and those of the sheep and guinea-pig, and to refer to the power of my own leucocytes and the living phagocytes in different samples of pus to ingest red corpuscles, so agglutinated or opsonized.

Experiment 1.—Six separate drops of a serum agglutinative to C. J. B. red cells were placed on a glass plate in horizontal series (see upper row, Fig. II). Six corresponding drops from a non-agglutinating serum form the lower row. To each separate drop of serum in both rows one drop of an antiseptic reagent was added in the following order:

- (1) 1 drop 0.9 per cent. saline.
- (2) 1 drop 5 per cent. hypertonic saline.
- (3) 1 drop 4 per cent. chloramine-T solution.
- (4) 1 drop 2.5 per cent. carbolic acid solution.
- (5) 1 drop 0.1 per cent. mercury biniodide solution.
- (6) 1 drop 0.1 per cent. acriflavine solution.

The reagent was first mixed with the serum, and then to each drop was also added a measured quantity of human (C. J. B.) red corpuscles previously washed in normal saline.

The corpuscles were then thoroughly mixed with the antisepticized serum in each drop.

This experiment shows that when certain antiseptics are added to blood serum the agglutinative effect on the red cells varies according as the serum is or is not an agglutinating serum. Thus in the upper row (an agglutinating serum) the addition of normal saline shows the normal agglutination and serves as a control. The hypertonic saline, chloramine, and carbolic acid give no

FIG. I.—Showing types of haemagglutinating serums. *Blood Serum W*: Non-agglutinative to human (C. J. B.) and sheep's cells. *Blood Serum 4*: Agglutinative to human (C. J. B.) and sheep's red cells. *Blood Serum 1*: Agglutinative to human (C. J. B.), non-agglutinative to sheep's red cells.

FIG. II.—Showing the action of antiseptics on an agglutinating serum (upper row), and on a non-agglutinating serum (lower row). 1, Normal saline; 2, 5 per cent. saline; 3, chloramine-T 4 per cent.; 4, carbolic acid 2.5 per cent.; 5, mercury biniodide 0.1 per cent.; 6, acriflavine 0.1 per cent.

FIG. III.—Showing the action of antiseptics on human red corpuscles (C. J. B.) without blood serum. 1, Normal saline; 2, 5 per cent. saline; 3, chloramine-T 4 per cent.; 4, carbolic acid 2.5 per cent.; 5, mercury biniodide 0.1 per cent.; 6, acriflavine 0.1 per cent.; 7, iodine 0.1 per cent.

FIG. IV.—Showing the reagglutination of red cells by agglutinating and non-agglutinating serum (upper row), after previous treatment by an agglutinating serum and the removal of the agglutinins by washing in saline. In the lower row the first agglutination was produced by acriflavine.

FIG. V.—Showing the effect of removal (by saturation) of the specific haemagglutinin, for human and sheep's red cells respectively, from a serum (5) agglutinative to both human (C. J. B.) and sheep's red cells. Upper row: A, after saturation with sheep's cells. Lower row: B, after saturation with human cells.

FIG. VI.—Showing the effect of different antiseptics on a heated agglutinating serum (upper row), and on a heated non-agglutinating serum (lower row). 1, Normal saline; 2, 5 per cent. saline; 3, chloramine-T 4 per cent.; 4, carbolic acid 2.5 per cent.; 5, mercury biniodide 0.1 per cent.; 6, acriflavine 0.1 per cent.; 7, iodine 0.1 per cent.

FIG. VII.—Showing the action of different antiseptics on an agglutinating liquor puris (upper row), and on a non-agglutinating liquor puris (lower row). 1, Normal saline; 2, 5 per cent. saline; 3, mercury biniodide 0.1 per cent.; 4, chloramine-T 2 per cent.; 5, iodine 0.1 per cent.; 6, acriflavine 0.1 per cent.

agglutination: mercury biniodide, acriflavine, and iodine (in a less degree) all give a well-marked agglutination.

In the case of the non-agglutinating serum in the lower row treated with the same reagents none of the drops show any agglutinative change.

This shows that it is essential to ascertain the agglutinative capacity of any serum before using it as a test of the action of antiseptic reagents. In the case of the hypertonic saline a transient initial agglutination occurs with an agglutinating serum, but this soon disappears. Chloramine, carbolic acid (in the strengths used) both cause destruction of the red cells and laking of the haemoglobin. This also occurs with all the other antiseptics after a lapse of time with the exception of the hypertonic saline.

Before drawing any inference it is necessary to check this observation with a similar series showing the effect of the same antiseptics on washed red cells without the addition of any blood serum. Fig. III shows the result. To each drop of different antiseptic solution a measured quantity of washed and sedimented (C. J. B.) red cells was added in the following order:

- (1) Normal saline.
- (2) 5 per cent. saline.
- (3) Chloramine 4 per cent.
- (4) Carbolic acid 2½ per cent.
- (5) Mercury biniodide 0.1 per cent.
- (6) Acriflavine 0.1 per cent.
- (7) Iodine 0.1 per cent.

None of the reagents in the strengths used, except acriflavine, cause agglutination. Iodine 0.2 per cent. also does so; but it must not be inferred from this that acriflavine and iodine are more toxic to red cells than the other antiseptics. As a matter of fact they are less toxic, and the absence of agglutination in the case of chloramine and carbolic acid is due to the destructive action of these reagents on the red cells.

The Capacity for Reagglutination shown by Red Cells which have been Previously Agglutinated by Serum or by Antiseptic Reagents.

There is also another way in which we can test the action of antiseptics on red corpuscles. A measured quantity of washed human (C. J. B.) red cells was added to known volumes of the different antiseptic solutions to be tested. Corpuscles and solution were thoroughly mixed and allowed to stand together for half an hour. The mixture was then centrifugalized and the sedimented corpuscles washed free of all antiseptic admixture in several changes of normal saline. The result of submitting red cells previously so treated to the action of an agglutinating and a non-agglutinating serum respectively seems to vary somewhat according to the antiseptic used, and whether it does, like flavine, or does not, like chloramine, itself produce an initial agglutination, and whether it does or does not destroy the red cells. In general terms we find that red cells which have been treated with antiseptic reagents (which do not destroy the corpuscles or lako the solution) do, after washing in saline, reagglutinate when mixed with an agglutinating serum. This is true of normal saline, hypertonic saline, acriflavine, and hydrogen peroxide. In some cases the effect of the antiseptic seems to be to sensitize the corpuscles and render them more susceptible to reagglutination. Thus red cells agglutinated by acriflavine in some specimens reagglutinate when mixed with a non-agglutinating serum. It is of great interest to find (see Fig. IV) that this is also true of red cells previously agglutinated by contact with an agglutinating serum without any antiseptic. The experiment also shows that (as far as haemagglutinins are concerned) it is possible to wash away the agglutinating substances from the surfaces of the corpuscles, leaving them again susceptible, and in some cases more susceptible, to the influence of a second dose of agglutinating serum. Bearing in mind the very close analogy between the haemagglutinins and the bacterial agglutinins it is probable therefore that this is true also of the latter bodies. The serum used to agglutinate and sensitize the red cells was also tested after centrifugalization and was found to have lost all its agglutinative content.²

The Effect of Antiseptics on Heated Serums.

We have seen that the effect of an antiseptic on the agglutinative capacity of a blood serum depends on the

inherent capacity of that serum to agglutinate red cells. But it also depends on whether the serum is in the normal condition or whether it has been heated. We know that the haemagglutinins are thermostable at a temperature of 56° C., so that the difference in result cannot be simply due to destruction of haemagglutinins. Fig. VI shows the effect of different antiseptics on a heated agglutinating serum (top row) and on a heated non-agglutinating serum (lower row).

The effect of heating for half an hour at a temperature of 56° C. on an agglutinating serum is to increase agglutination. It now occurs with carbolic acid and hypertonic saline when red cells are added, and even with chloramine an initial slight clumping takes place. In the case of the non-agglutinating serum (lower row) agglutination is absent in all the drops.

In order further to analyse the effect of heating an agglutinating serum, the influence of acriflavine and iodine, when added to the serum in different degrees of dilution, was examined in detail. Dilutions in normal saline of a non-agglutinating serum in strengths of 1 in 10, 1 in 15, 1 in 20, 1 in 40, 1 in 80, 1 in 100, 1 in 200, 1 in 300, 1 in 400 were made. The point was then found at which the addition of an equal volume of this diluted non-agglutinating serum neutralized the agglutinative effect of a drop of acriflavine 0.1 per cent. and iodine 0.1 per cent. respectively when mixed with the serum. This point was found to lie just below 1 in 300 in the case of the iodine solution, and 1 in 400 in the acriflavine solution. Evidently it only requires an extremely small quantity of a non-agglutinating serum to prevent the agglutinating action of these antiseptics.

It is interesting to consider for a moment how this inhibition may be brought about. Unlike serum, which acts specifically on the red cells, the antiseptic acts non-specifically both on the serum and on the red cells, combining with protein elements in both. If there are available proteins in the serum, other than agglutinins, capable of combining with the unsatisfied element in the antiseptic, then the corpuscles may escape injury. If, on the other hand, there are no available proteins in the serum, or if they have been destroyed by heat, then the full effect of the antiseptic will fall upon the red cells. Antiseptic reagents vary in the avidity with which they combine with serum proteins, and thus in their toxicity to the red cells.

An attempt was also made to ascertain the amount of non-agglutinating serum that must be added to an agglutinating serum in order to neutralize or inhibit its agglutinative power. An agglutinating serum was diluted four times with a non-agglutinating serum. At this stage of dilution, although it agglutinated red cells, the reaction was incomplete. Clumping occurred on gentle movement, but on standing the agglutination disappeared, to reappear again on movement, just as a freshly formed precipitate may redissolve in excess of the reagent used.

The Specific Character of the Different Haemagglutinins.

It is known that an agglutinating serum may contain different haemagglutinins, each separately capable of clumping the red cells of another individual or those of a certain species of animal. The following experiment shows that it is possible to remove one kind of haemagglutinin from a serum without removing the others. Two separate measured volumes were taken of a serum agglutinative to human and sheep's red cells; one volume (a) was shaken up with washed sheep's red cells, and the other volume (b) with washed human (C. J. B.) red cells. Both were centrifuged, and the clear serum tested for agglutinative capacity. Volume (a) was found to have entirely lost the power of agglutinating sheep's red cells while still clumping human corpuscles, while volume (b) had retained its capacity to agglutinate sheep's cells but had lost the power to agglutinate human cells. As in the case of the bacterial agglutinins, therefore, the haemagglutinins are specific for different varieties of red cells, and the same serum may contain a number of haemagglutinins. Fig. V shows the result of this experiment.

The Action of Haemagglutinating Serums on "Whole" Foreign Blood—"Drop and Pool" Method.

So far we have only dealt with the influence of different antiseptics in favouring or inhibiting the tendency of red

blood corpuscles to clump together under suitable conditions. Before we draw any inferences as to the toxic action of these reagents on the serum, the red corpuscles or the leucocytes, it is necessary to ascertain what action different serums of different agglutinative capacity exercise on the whole blood of another individual (C. J. B.) without the addition of any antiseptic (Fig. VIII).

FIG. VIII.

One or more drops of the serum to be tested are placed within a vaseline or plasticine cell. Into the centre of the little pool of serum so enclosed a small drop of blood from the finger is allowed to fall; the cell is closed by a cover-slip. After incubation the cover-slip and cell wall of this emigrating chamber are removed, the blood clot and serum are gently washed away with normal saline, and the film of emigrated leucocytes fixed and stained with 1 per cent. iodine solution. The extent to which the toxic or agglutinative action of the serum affects the activities of the leucocytes from the periphery towards the centre of the drop of blood affords a rough quantitative test of the toxic capacity of the serum by which the drop of blood is bathed, and the extent to which the foreign serum has neutralized the normal serum of the blood tested.

If the foreign serum used be an iso-haemagglutinating serum then the (C. J. B.) red blood cells clump, but a further change also takes place. The white blood cells which have emigrated from the clot on to the slide will not only be covered with attached clumps of red cells, but some of the leucocytes will contain ingested red corpuscles. The agglutination of the (C. J. B.) red cells occurs in relation to their own (C. J. B.) leucocytes, and the adhesiveness is mutual, not only between individual red cells, but also between red cells and the surface of the leucocytes. This clumping and ingestion of red cells by native leucocytes in the presence of a foreign iso-haemagglutinating serum throws light on an important biological problem, namely, the relation of the agglutinins to the opsonins, and will be referred to later. Meanwhile, another fact of importance must be mentioned. A given serum may exercise a powerful agglutinative effect on the red cells and yet be relatively innocuous to the white blood cells. These, when incubated with such a serum, may emigrate and adhere to the slide in large numbers, and exhibit a considerable capacity for elaborating iodophil substances. On the other hand, a non-agglutinating serum may prevent emigration and the formation of iodophil substance. It may poison the leucocytes and yet fail to agglutinate the red cells. In fact, the leucotoxic effect and the haemagglutinative effect of a serum may vary independently.

Haemagglutinins in Pus.

Samples of pus have been collected from a considerable number of wounds dressed with normal saline in order to avoid the complicating effect of antiseptics. The pus has been centrifuged, and a drop of the liquor puris placed on a glass slide and a given volume of washed red cells, human, sheep's, or guinea-pig's added. The result has been to show that in most cases the liquor puris agrees in agglutinative content with the blood serum of the patient. If this is haemagglutinating, then the liquor puris is haemagglutinative also. Not only is this true of the effect of the liquor puris on human red cells, but it is true also of the red cells of different species of animals.

The Effect of Heat on Liquor Puris.

The effect of heating liquor puris for half an hour at 56° C. is, to a certain extent, the same as in the case of the corresponding blood serum. An agglutinative liquor puris retains its agglutinative capacity, while a non-agglutinating liquor puris remains non-agglutinative.

The Action of Antiseptics on Liquor Puris.

Not only does the purulent discharge from a wound faithfully reproduce the agglutinative characteristics of the blood serum of the patient, but it continues to do this, within limits, independently of the kind of infection present in the wound, or the kind of antiseptic reagent with which

the wound is dressed. It is evident that this retention of agglutinative capacity in a fluid like pus affords a means of ascertaining the degree of decomposition going on in the discharge and the extent to which its vitality has been affected by the growth of micro-organisms in the wound or by antiseptic dressings. I have been surprised at the tenacity with which an agglutinating pus from a heavily infected wound will retain its power of agglutinating human red cells. Even pus recovered from a piece of gauze dressing soaked in normal saline which had lain on a granulating wound for twelve hours yielded a liquor puris agglutinative to human red cells; but this will not be the case, of course, unless the patient's serum is also haemagglutinative. These observations are of interest as confirming the fact, not only that the purulent discharge from most wounds contains many living pus cells, but also that, from the humoral point of view, pus may be sufficiently living to contain agglutinins.

Fig. VII shows the action of different antiseptics on an agglutinative liquor puris (upper row) and on a non-agglutinative liquor puris (lower row). The reagents added to the liquor puris are the same as those used in the case of the blood serum, and there is a striking similarity in the reaction in both cases. In the upper row agglutination occurs with normal saline, mercury, and acriflavine, and slightly with iodine, but no agglutination is seen in any of the drops similarly treated in the lower row in which the liquor puris is itself non-agglutinative.

Summary of the Action of Antiseptics on the Cellular and Humoral Elements of Blood and Pus.

1. On the red blood corpuscles. It is, I think, clear that we may divide antiseptic reagents into two groups: (a) Those which agglutinate red blood cells without destruction of the corpuscles; (b) those which haemolyze the red cells without producing agglutination. Acriflavine and 5 per cent. saline are examples of the first group, and to a less degree mercury biniiodide and iodine, though these produce a certain amount of laking. Chloramine and carbolic acid belong to the second group. The test of the absence of haemolysis is the capacity of previously agglutinated red cells to re-agglutinate, after thorough washing, when again mixed with an agglutinating serum. Acriflavine and hydrogen peroxide seem to favour this result.

2. On the leucocytes and pus cells. It is useful to distinguish between those reagents which inhibit emigration of leucocytes from the blood clot when incubated with the whole blood in a closed cell and those which allow of free emigration and the elaboration of iodophil substances by the phagocytes. Judged by this test, acriflavine in strengths below 1 in 2,000 in normal saline seems to be only slightly injurious to the leucocytes when incubated with whole blood. An interesting fact has been observed when serum or liquor puris has been incubated with acriflavine in 1 in 2,000 concentration in normal saline. Any leucocytes or pus cells or organisms present in the serum seem to become, when incubated with acriflavine in serum, peculiarly sensitive to iodine when this reagent is subsequently added in 1 per cent. solution. The combination of serum, or liquor puris, acriflavine, and iodine together brings about a blue-black staining of the leucocyte granules. The organisms also show up as black bodies when ingested by the leucocytes, and the blue-black colour of the granules suggests the colour reaction formed when iodine is added to certain carbohydrate substances. With regard to pus cells, capacity to ingest pigment granules and to elaborate iodophil substances in the presence of antiseptic reagents affords a working test of vitality, and this has been used as the test of leuco-toxicity in the antiseptics used. The test has been applied in two ways: (1) *In vivo*, by the addition of sterilized starch grains or pigment granules to the antiseptic used for dressing the wound. The number of pus cells which contain starch grains or pigment affords evidence of phagocytic activity in the presence of the antiseptic in the wound. (2) *In vitro*, pus cells from the wound have been incubated with the antiseptic and the starch grains in a closed cell. Judged by this test acriflavine compares favourably with mercury, carbolic acid, chloramine, and hypertonic saline.

3. The action of antiseptics on the blood serum. The inhibition of the capacity of an agglutinating serum to agglutinate washed red cells provides a test of disintegrative action on the serum by the antiseptic employed. Here

also reagents can be divided into two groups—(a) those which destroy the haemagglutinins in the blood serum, and (b) those which do not. Chloramine, carbolic acid, and hypertonic saline belong to the former, and acriflavine, hydrogen peroxide (in certain concentrations), and iodine to a less degree, to the latter.

The Relation of the Haemagglutinins to the Bacterial Agglutinins.

There does not appear to be any essential connexion between these two constituents of the blood serum. From a small number of observations kindly made for me at the 5th Northern Base Hospital by Dr. Agnes Porter we find that a serum of high haemagglutinative capacity may have very little power of agglutinating certain varieties of bacteria and cocci, and vice versa.

The Relation (if any) between Haemagglutinin Content and Leuco-toxicity of a Blood Serum.

Reference has already been made to the fact that different serums (from healthy persons) vary greatly in their action on the white blood corpuscles of another individual when these are incubated with such a foreign serum, and the question arose whether any association could be traced between high haemagglutinative content and marked leuco-toxicity, or vice versa. As far as my observations go, I have not been able to trace any such association. It is probable, therefore, that leuco-toxicity is associated with the presence of other bodies in the serum and not the haemagglutinins.

The Relation of the Haemagglutinins to the Opsonins.

I have already spoken of the mutual reaction which takes place between leucocytes (or pus cells) and red corpuscles when the latter agglutinate in the presence of the former. Many samples of pus from infected wounds have been centrifuged. If the liquor puris proved to be agglutinative to my own or to sheep's red cells, some of the pus cells after thorough washing in saline have been incubated in a closed cell with human (C. J. B.) or sheep's washed red cells. As a general rule, ingestion of red cells does not take place under these conditions by thoroughly washed pus cells or by washed leucocytes; but if a drop of the agglutinating liquor puris be added before incubation the pus cells will take up the red cells. If ingestion is about to take place the red cells clump and adhere to the leucocytes as well as to each other. I have, however, found that thoroughly washed pus cells from an agglutinative pus will sometimes ingest sheep's red cells in the absence of any liquor puris. This suggests that sheep's cells may require less opsonizing than human cells, or that the pus cells elaborate fresh haemagglutinins.

A further point also requires notice. When red cells are added to healthy pus from a patient whose blood serum contains haemagglutinins, not only do the red cells clump together and adhere to the pus cells, but the pus cells also agglutinate in masses. This can be seen by mixing a drop of such pus on a slide with normal saline. Washed red cells are then mixed with the thinned pus. After a short incubation period a gentle rocking movement of the slide will bring about not only a clumping of the red cells but also a massing of the leucocytes in groups.

The effect of agglutinative liquor puris has also been tested on whole blood by the "drop and pool" method. Liquor puris obtained by centrifuging pus from a wound in a patient with a haemagglutinating blood serum is placed in a closed cell. Into the centre of the pool of liquor puris a drop of blood (C. J. B.) from the finger is allowed to fall and the cell closed and incubated. On removing the cell walls and gently washing away the central blood clot the opsonizing effect of the liquor puris on the red cells can be observed. If highly toxic, no emigration of leucocytes takes place, but if the liquor puris is healthy (that is, from a well drained, healthy wound), numbers of cells will emigrate on to the slide, some will show the iodophil reaction, and some, generally in the peripheral zone, will be covered with clumped red cells, while a certain number will have ingested some of the red cells which adhere to them (Fig. IX).

Thus, by the addition of a haemagglutinin to a liquor puris or a serum, we can induce the leucocytes to phagocytose native red cells—that is, red cells from the same blood—when incubated together. Iso-phagocytosis of red

cells by pus cells may also be observed in pus from wounds in patients whose blood serum is haemagglutinative.

Thus we arrive at this position. Pus cells from "whole" pus (if it contains haemagglutinins of the right kind) will ingest washed human red cells more freely than washed

FIG. IX.—Showing the phagocytosis of (C. J. B.) red cells by C. J. B. leucocytes in a drop of C. J. B. blood incubated in agglutinating liquor puris: "drop and pool" method. (Drawing from microscope slide.) 1, Agglutinated red cells; 2, red cells in phagocyte.

pus cells from the same pus will digest them, although the washing in saline actually increases the activity of the cells by removing the bacterial toxins and tryptic content of the liquor puris. The difference in the two cases depends on the fact that haemagglutinins are present in the "whole" pus and absent in the washed cells. Moreover, no ingestion of red cells occurs if the "whole" pus is non-agglutinative.

Putting all these facts together, we must, I think, conclude that, as far as the phagocytosis of red cells by leucocytes is concerned, haemagglutinins also act as opsonins and prepare the red cells for ingestion.³

The question remains as to the origin of the haemagglutinins in the blood serum. The fact that washed agglutinative pus cells may clump and ingest sheep's red cells in the absence of liquor puris suggests that in some cases the phagocytes can elaborate their own agglutinins and opsonins, but further work on these lines is required in this difficult field.

The Relation (if any) between the Presence of Haemagglutinins in the Blood Serum and Pus and Capacity to Resist Infection.

It is a matter of great interest to ascertain whether patients whose blood serum contains any of the various haemagglutinins for human or animal red cells show a greater or a less power of resisting infection than patients whose blood serum and pus are not agglutinative.

The subject is a difficult one. I have examined the pus, after confirmatory examination of the blood serum, from a considerable number of patients from this point of view, together with, in some cases, a bacteriological examination of the wound discharges. In the absence of recorded facts about the blood serum before the injury, I cannot satisfy myself that any constant association exists between haemagglutinin content of serum or pus and resistance to infection in any given case. At the same time there can be little doubt that a detailed examination of the blood serum and pus from a large series of cases, checked by bacteriological data concerning the nature of the infection and clinical findings bearing on recovery, would not only solve this question, but would throw valuable light on fundamental problems connected with the production of the immune state.

There is, however, some evidence that the blood serum of a patient previously known to be non-agglutinative to human (C. J. B.) red cells may, under the influence of a heavy systemic infection, become agglutinative to the same red cells. This fact, if confirmed in other cases,⁴ is important, because it is possible that the increase in

³ This has now been confirmed in quite a number of patients.

haemagglutinin content may serve as an indication that other collateral changes—that is, increase in antibodies and opsonins—are also occurring in the same blood serum.

Further, pus cells from a wound in a patient whose blood serum contains haemagglutinins frequently contain ingested red corpuscles. The pus cells in the presence of the iso-haemagglutinins (or the opsonins if these are separate bodies) tend to become auto-haemagglutinative and ingest their own red cells. Pus cells from wounds in patients whose blood serum contains no haemagglutinin do not phagocytose their own red cells.

It is probable that the red cell destruction and anaemia which accompany systemic infection in certain cases are associated with a blood serum and liquor puris of a haemagglutinative character.

In connexion with this inquiry, I wish to acknowledge kind help from my colleagues in military hospitals and from Dr. Mackarell, pathologist to the Leicester Royal Infirmary. The figures in the special plate are reproduced from photographs.

ON WAR NEPHRITIS AND SOME CIRCUMSTANCES INCIDENTAL THERETO.

BY

SIR THOMAS OLIVER, M.D., F.R.C.P.,

NORTHUMBERLAND WAR HOSPITAL, GOSFORTH, NEWCASTLE-UPON-TYNE.

It was not until fully eight months after the commencement of the war that nephritis loomed large in the sickness returns of soldiers. In the case of the German army the outbreak occurred a few months later. The fact that the winter campaign had been got over and the spring and early summer months had come was advanced by some physicians as a reason why exposure to cold could not have been the cause of the disease. The malady has fallen upon our troops in France and Flanders with unequal incidence and with unequal severity. Occasionally the number of men from one convoy admitted for nephritis under the care of my colleague Dr. Dagger and myself has equalled 40 per cent. of the total, while on other occasions there would be only 10 per cent. or less. It is sometimes said that the number of cases of nephritis among our soldiers at the front has not been larger than that occurring among the civil population. I can hardly subscribe to this opinion, and I base my dissent upon experience of admissions into the Royal Victoria Infirmary, Newcastle, extending over three decades. In the summer of 1915 few of the cases of nephritis admitted into the Northumberland War Hospital presented acute symptoms. This might be explained partly by the fact that the severer and more acute cases had been retained in hospitals on the Continent. Beyond albuminuria and complaints of headache and backache, there were few physical signs and symptoms. Oedema, with us, has been an infrequent physical sign compared with the experience of Colonel J. Michell Clarke,¹ who found it in fifty-seven out of seventy-four patients. It was during my first visit to France in September, 1915, that I saw in the stationary hospitals there cases of nephritis with acute symptoms, including dropsy and uraemia.

War nephritis, to give it the name by which it is generally known, differs from ordinary nephritis in that there is a greater tendency for blood, and blood in fairly large quantity, to appear in the urine, for the specific gravity in many cases to be well maintained, for the urine to be not so scanty, the blood pressure to be lower, also for the malady to be attended by fewer cardio-vascular changes, and to be followed by fewer complications than are found in ordinary nephritis.

We have had no deaths from war nephritis in the Northumberland War Hospital. Hurst² states that death in this malady is extremely rare, not more than 3 or 4 per 1,000 patients, and that when death takes place it is usually through uraemia. A low death-rate has also been noted in the Italian army. On the other hand, and as illustrating the absence of uniform experience, three of Colonel Michell

Clarke's 68 patients died. A fair percentage of our patients at the Northumberland War Hospital have recovered, but in men over 30 years of age albuminuria has frequently persisted, the urine has become pale and watery, and its specific gravity has decreased. Many of these men have become the subjects of chronic kidney disease. In a considerable number of the younger men recovery has only been apparent, for albuminuria after having been absent for days or weeks has returned, without any exaggeration of the symptoms, other than fresh complaint of backache and the presence of blood in the urine. The length of time required for the disappearance of the albuminuria varies—it may be three weeks or it may be as many months, but the longer it persists the more likely are the kidneys to become the seat of chronic and permanent structural changes. While error in diet is a cause of recrudescence of symptoms, muscular exercise—for example, tennis playing and too long walks—may also conduce to their return.

I have alluded to the fact that in war nephritis there are fewer symptoms and cardio-vascular signs than in the usual forms of nephritis with which we are familiar, hence the comparative absence of well-marked hypertrophy of the left ventricle of the heart and of loud accentuation of the second sound over the aorta. The short duration of the illness may partly, but it cannot altogether, explain the comparative infrequency of cardiac hypertrophy, and of thickened arteries.

I have not been able to ascertain how far the previous occupation of the soldier plays any part in the development and course of the malady. On the Italian front it has been observed that men whose previous occupations exposed them to hardships and who were intemperate have suffered from nephritis in larger numbers than men engaged in more protected occupations and who are of temperate habits.

Some of the soldiers were slightly anaemic, but they seldom exhibited the well known features of patients suffering from Bright's disease. I have not found any well marked reduction in the number of red blood corpuscles, nor any increase or decrease of leucocytes, nor has basophilia been a feature of the blood examinations. Of the presence of eosinophile corpuscles in the urine and their excess in the blood as described by Bernhard I have no experience. A positive Wassermann reaction was not obtained in a series of 13 of my cases. McKenzie Wallis obtained a positive reaction in 18 out of 56 patients. Since other physicians have secured the reaction, and seen relief follow antisyphilitic treatment, it is possible that syphilis is more than an incident in some forms of war nephritis. The blood pressure has varied from 70 to 130 mm. Hg; in only a small percentage did it rise to or over 180. Some of the soldiers were admitted into the hospital not for kidney trouble at all, but for trench fever, P.U.O., or on account of having been gassed.

SYMPTOMS.

The disease usually commences with a feeling of malaise, pains, especially in the limbs and back, headache, and occasionally sickness with oedema of face and feet. Among German soldiers the disease is said to be ushered in with cough, worst at night, and with shortness of breath, attended by oedema of face, and by thirst and scanty secretion of urine. Our own men, too, suffer at the onset from bronchitis and dyspnoea. By the time the patients have reached the North of England dropsy, if ever present, has usually disappeared. Anasarca we never see. In none of our patients has vision been affected, nor have there been uraemic convulsions. One patient developed acute pulmonary oedema, and, after a serious illness, made a good recovery from the lung trouble, but albuminuria still persisted. It would be interesting to know what the experience of the R.A.M.D. is in regard to the future of the men who have been treated for nephritis, who recovered and were, in the early months of the war, again sent back to the front. Since in a fairly large percentage of patients who have been suffering from nephritis relapses occur, no case should be regarded as cured until, after several months have passed, it is found that, on full diet and after muscular exercise, albumin does not reappear in the urine.

ETIOLOGY.

The causation of war nephritis is obscure. Although the urine and the blood of my patients have on several occasions been examined bacteriologically, in none of them

was a specific micro-organism found to explain the illness. The *Bacillus coli* was found in several of the urines; and while the presence therein of this organism would suggest an intestinal origin of the nephritis, I can hardly regard this as the cause, especially as the patients did not give a history of diarrhoea or of intestinal disturbance.

M. Saequepée³ draws attention to the fact that cultures from the blood and from emulsions of kidney and spleen in nephritis contained a polymorphous bacterium and cocci bacilli of two kinds, one short and the other long. These organisms, when injected into guinea-pigs and mice, caused oedema and haemorrhagic lesions in the internal organs similar to those found in the patient who had died from nephritis, and from whose blood the cultures were obtained. The fact that until now no specific micro-organism has been found in the blood and urine of our soldiers suffering from nephritis is no proof, of course, that the malady is not of an infectious origin, for after all—so far, at any rate, as the urine is concerned—micro-organisms may fail to pass through the renal barrier, and yet their toxins be capable of doing a considerable amount of damage.

Exposure.

Most of the men attribute their illness to exposure to wet and cold in the trenches and dug-outs. It is difficult for any one who has visited the trenches, as on three occasions I have, and seen the soldiers in cold, damp, and snowy weather lying in their wet clothes, to exclude altogether exposure to wet and cold as a direct or indirect cause of the malady. It is an interesting point, therefore, as to how far we are to regard the nephritis we are discussing as an incident of trench warfare and of campaigning in the open. As a consequence of the routine four days spent in the trenches and of exposure to wet and cold we can readily understand the rheumatism and muscular pains the soldiers complain of. Is there any reason why the conditions which give rise to the joint and muscular pains should not in some instances operate upon a larger area of the body so as to include the kidneys as well? The vessels of these organs are extremely sensitive to external changes of temperature. Nephritis is apt to follow chilling and wetting of the lower extremities; hence its frequent occurrence in men employed in making drains. It occurred, too, with great frequency in the German soldiers when they slept on the bare pavement without a covering of straw, and it ceased when they slept on wood. Nephritis also occurred in the Italian army when, during the month of May, one blanket was withdrawn, and it disappeared on the blanket being restored and warmer clothing supplied.

Colonel Manella, sanitary director of one of the Italian army corps, has drawn attention to the fact that in his area there are nephrogenous zones where nephritis is met with in greater proportion than in other areas. A fact equally interesting is that in these Alpine regions few cases of nephritis occur at high altitudes where the air is cold and dry compared with lower altitudes where the air is damp and cold.

Professor Luigi Devoto of Milan, in an article on acute nephritis among troops at the front,⁴ attaches considerable importance to the influence of damp and cold. In one sector of the front, at an altitude of 1,250–2,600 metres, out of 1,200 soldiers the following cases of nephritis occurred:

1916.		1916.	
June ...	5	December ...	7
July ...	10		
August ...	11	1917.	
September ...	13	January ...	7
October ...	19	February ...	9
November ...	5	March ...	1

The largest number of cases occurred in the autumn.

Antecedent Nephritis.

In many of the men affected there may have been a latent nephritis, ready to be lit up on slight provocation; but in a large number of my patients, especially the younger men, interrogation failed to reveal the existence of previous kidney trouble as evidenced by oedema, headache, backache, vomiting, and scanty urine. On the other hand, it is a possibility which should not be ignored, although the absence of hypertrophy of the left ventricle and high blood pressure point in a negative direction.

Postural albuminuria also must not be lost sight of. Reher and Lauer, who examined the urine of Swiss

soldiers who belonged to the 34th Battalion Mounted Infantry, found albumin in the urine of a large percentage of the soldiers who had remained many hours in an erect position during extremely cold weather.

Haematuria.

Haematuria is a frequent sign. It may disappear and return on the slightest provocation. Its return has in some of my cases been associated with large quantities of oxalates in the urine. Nonnenbruch of Wurzburg⁵ states that 50 per cent. of the patients admitted into his hospital had haematuria. My experience is that it is only about 20 per cent., but this varies. It may be that the haematuria is simply the bleeding which occurs in chronic interstitial nephritis, also that in many instances the kidney disease of the soldiers is the result of an old infection, such as scarlet fever or diphtheria. It is impossible to say to what extent the patient in every instance was in good health previous to joining the colours. In the case of some of the men over 40 years of age there was probably latent kidney disease or renal inadequacy. Taking twenty-eight of my patients at random, I find that there were nine cases of nephritis in men between the ages of 30 and 35, seven between 35 and 40, six between 20 and 25, three between 25 and 30, and two between 40 and 45. There is no unanimity of pathological opinion as to the nature of the nephritis. The character of the urine suggests that it is parenchymatous, while the pain in the loins and the recurring haematuria, the blood being frequently in large quantity, indicate an enlarged and swollen kidney, the pain in the back being due to stretching of the capsule.

Professor H. Ziemann and Dr. Oehring of Saarburg⁶ found that of 2,011 patients admitted into their hospital 2.93 per cent. were suffering from war nephritis, and that of these 1.4 per cent. were the subjects of nephritis in an acute form, 0.145 per cent. of chronic nephritis, 0.78 per cent. of temporary albuminuria, and 0.34 per cent. of albuminuria of greater persistence; 0.24 per cent. suffered from albuminuria with complications.

Lead in the Urine.

Setting aside the influence of exposure to wet and cold as a possible cause of the type of nephritis we are discussing, other causes may be in operation—for example, infection and the influence of poisons, organic and inorganic. C. Powell White found lead in the urine of four soldiers suffering from kidney disease, and tin also in the urine of one of the men. Mackenzie Wallis did not find any trace of lead in the urine of his patients. Mr. T. M. Clague, analytical chemist, Newcastle-upon-Tyne, has made for me analyses of the urine of several of the sick soldiers under my care in the Northumberland War Hospital. The urines were those of men of different convoys, and the results are as follow:

Of five samples of urine of different patients two contained lead; of eight samples five contained lead; of five samples of urine one contained lead, and of three samples one contained lead.

Several single samples were, in addition, examined and found to be free from lead—others showed mere traces of the metal.

In twenty-nine samples of urine of soldiers in the Northumberland War Hospital lead was found nine times, or in something like 43 per cent.

This is a large percentage of cases with lead in the urine. Care was taken to eliminate the possibility of drugs having been taken, such as bismuth for example.

These observations raise the question, How did lead get into the system? Powell White found that a salt solution boiled in a meat tin extracted both lead and tin. At my request, Mr. Clague submitted the meat which the soldiers are receiving at the front—namely, bully beef and Maconachie—to analysis; he found traces of lead in the meat, but the amount was so infinitesimal that it raised doubts as to whether this could be the source of the metal in the urine of nephritic soldiers. I then had metallic scrapings of the interior of the pans in which the food is cooked at the front tested, but no lead was found therein; the metal present was mostly calcium. One possible source still remained, and that was the drinking water, and as this was frequently delivered to the soldier in cleansed petrol tins, we tried the effect of various kinds of water, sterilized and non-sterilized, chlorinated and not, upon the tins, but without obtaining lead.

The etiology of war nephritis is still obscure. I have not dealt with such a possible cause as the combined

influence of overwork, fatigue, and the physical discomfort of life at the front.

Recent findings have led me to give some attention to the possible effects of bullet and shrapnel retained in the body. In the urine of a young corporal with a bullet in his right thigh we found lead; in that of a sergeant shot through the arm and chest, and with the metal retained in the chest, lead was also found; in the urine of a soldier with pieces of shrapnel in knee and shoulder a small quantity of lead was found; while in the urine of a young lieutenant, mortally wounded, with shrapnel in his pelvis, lead was found. It is only right to add that in the urine of other soldiers with shrapnel retained in the body no lead was found, and that in the urine of one patient similarly circumstanced lead was on one occasion absent, while a fortnight after it was present. Although in cases where lead was found in the urine albumin was not present in every instance, yet in other instances there seemed to be a distinct connexion between the albuminuria and the retained shrapnel, as the following indicates:

I was asked by one of my surgical colleagues to see a young soldier with a piece of shrapnel in the front of the uppermost part of the left thigh. The patient was extremely ill. He had albuminuria, with recurring haematuria; the wound in the thigh kept closing and opening every now and then, attended by rises of temperature. The surgeon took the view that the wound would not heal on account of the condition of the patient's kidneys, which he thought antedated the receipt of the wound. My opinion was that the presence of the shrapnel in the body was the cause of the kidney trouble, and that if the shrapnel was removed the kidney trouble would cease. The patient was transferred to my own ward, where, by external applications aided by natural processes, the shrapnel gradually came nearer the surface, and could be readily felt under the skin. As the patient was too ill to be given a general anaesthetic, local anaesthesia was employed and the shrapnel removed by the surgeon. From the date upon which the shrapnel was removed the temperature gradually fell to the normal, the wound closed, the albuminuria entirely and permanently disappeared, and the patient made a good recovery.

It has been the practice of surgeons during this war where pieces of projectile have become embedded in the tissues, are not readily accessible, are not pressing upon nerves or upon important organs, and where there is neither haemorrhage nor excessive suppuration, to leave the metal in the body undisturbed. There is always the possibility of the piece of shrapnel or bullet becoming encysted and remaining as an inoffensive foreign body. Yet, now and again, it has happened that some of these metal carriers whose wounds have healed have been observed to become anaemic, to be suffering from disorders of the intestinal and nervous system and to have become the subjects of albuminuria. Since in their urine lead is frequently found, it is clear that resorption of the metal must be taking place. It goes without saying that pieces of shrapnel are more likely to cause plumbism than portions of shell. All depends upon the type of metal, the organ or tissues in which it is embedded, and whether there is or is not suppuration. In all cases, therefore, where pieces of shrapnel are retained in the body it would be well to have the patient's urine examined for lead.

As lending support to this, Loeper and Verpy⁷ may be quoted. They found lead in the urine of six out of sixteen soldiers in whose body pieces of projectile had been retained. They found it only with shrapnel and not with the debris of shell, also never when the bullet was intact. They found lead to the extent of $\frac{1}{2}$ to 1 mg. per litre of urine; in other words, that more than 1 mg. of lead was being eliminated in twenty-four hours. This is a smaller quantity than is occasionally found in the urine of lead workers, but it is equal in quantity to, or slightly more than, that found in the urine of persons poisoned by food or by drinking water contaminated by lead. When a wounded soldier with shrapnel retained in his body is passing from $\frac{1}{2}$ to 1 mg. of lead daily the kidneys in course of time are almost sure to become affected, for secondary lead compounds are being formed; these are absorbed, and pass on into the circulation. The extent to which this takes place will depend upon the leucocytes and the chemical activity of the tissues. Absorption of shrapnel is slow; lead does not appear in the urine until three to four weeks after a soldier has been wounded. When resorption of the metal is taking place there is a tendency in some instances for the blood pressure to rise, for albumin to appear in the urine, for the red blood cells to decrease in number, and for colic and constipation to be complained of. Since

in one of my own patients albuminuria and suppuration gradually ceased after removal of the shrapnel it would seem as if there had been a causal relation between the condition of the kidneys and retention of the metal in the body. I am not in a position to say whether the presence of shrapnel in the lung is more provocative of plumbism than when the piece of projectile is retained in the body elsewhere.

With the object of testing the solubility of lead bullets generally, and of throwing light upon the fate of shrapnel retained in the body and exposed to the influence of the fluids of the tissues, also to the influence of fat upon metallic lead, I secured the co-operation of Messrs. T. M. Clague and A. J. Watson, analytical chemists of this city, to whose report I invite attention.

EXPERIMENTS ON THE SOLUBILITY OF PLAIN LEAD AND ANTIMONIAL LEAD.

BY

T. MALTBY CLAGUE, Ph.C., and A. J. WATSON, Ph.C.

"CERTAIN clinical observations made by Sir Thomas Oliver suggested the desirability of an examination into the comparative solubilities in the fluids of the human body and in analogous liquids of the modern hardened bullet and the old bullet of pure lead.

"The uncoated shrapnel bullets used by the enemy and allied forces of to-day contain antimony in large amount (10 per cent. and upwards).

"Bullets were placed by us in the blood serum of sheep and macerated for seven days. After burning off, the residue was found to contain lead equivalent to 10 parts per million of the blood serum, but the analytical difficulties of dealing with the blood were great, and for convenience a solution was prepared containing 0.9 per cent. of NaCl and 0.13 per cent. NaHCO₃ to represent blood serum. Shrapnel bullets macerated for four days (heated each day to 35° C. (95° F.) for six hours) yielded in the case of pure lead 260 parts per million, and in the case of antimonial lead 300 parts per million.

"With a view to a more complete conformity to the conditions found in the human body an automatic circulating system was arranged in which an alkaline saline solution circulated through a U tube containing six bullets.

FIG. 1.—Water at 70° C. surrounded the limb of U tube containing the bullets; this caused the solution to circulate; the temperature did not rise above 25° C. to 30° C. After six hours' circulation, 20 c.cm. removed from Wolff bottle at position of least contact (x) contained 5 parts of lead per million of water; after fourteen hours' circulation it contained 7 parts per million. The liquid in the U tube was allowed to digest thirty-six hours in the cold and then removed. Pb content was found equal to 14 per million.

Antimonial Lead Bullet.

Oily Solvents.	Acidity.	Lead Yielded in Parts per Million of Solvent.
Lard	1.0	10
Neatsfoot oil	3.2	200
Suet	0.7	5
Olive oil	1.6	100
Liquid paraffin	0.0	Nil.

Bullets in solvent for six days heated to 35° C. (95° F.) each day for six hours.

Solubility of Bullets, Pure Lead, and Antimonial Lead.

Time.	Solvent.	Pure Lead.	Antimonial Lead.
		Per Million.	Per Million.
6 days (heated) ...	Neatsfoot oil (acidity 3.2)	200	200
	Olive oil (acidity 1.6)	300	200
4 days (cold) ...	Neatsfoot oil (acidity 3.2)	30	15
1½ days (heated) ...	Olive oil (acidity 1.6)	300	100

A piece of a lead bullet was placed in pus removed from a case of empyema. It was allowed to remain therein for forty-eight hours at a temperature of 40° C. On examination the pus was found to contain 12 parts of lead per million.

"The result of our experimental work shows that present-day hardened lead is soluble in the proportion of approximately three parts as against two and a half of pure lead in aqueous liquid, and that in fatty liquids or semi-liquids the pure lead is much the more soluble."

In addition to lead, shrapnel contains antimony and arsenic, and this raises the interesting question whether antimony and arsenic may not be absorbed as well as lead. It was common practice years ago in Germany, when horses were taken to market to be sold, for horse dealers to give to broken-winded animals a few ounces of small shot. This was followed by good effects which lasted for several days. The improved condition of the animals was attributed to the arsenic in the shot. We cannot, of course, compare the presence of shot in the alimentary canal of a horse with the retention of pieces of shrapnel in the lungs, the muscles, connective and adipose tissues of a wounded soldier. Apart from animal differences the metal in one instance is first exposed to an acid medium in the stomach, while in the other it is exposed to the alkaline juices of the tissues of the body, even allowing for the slightly acid reaction developed in actively contracting muscle. Experiments have been made in regard to this subject in Germany. Professor L. Lewin of Berlin, in a paper* on the toxic effects of arsenic in bullets, states that 10 grams of shrapnel containing 8 per cent. of antimony and 14 mg. of arsenic were broken up into numerous small pieces, placed in the undermentioned solvents in an Erlenmeyer's flask and kept at a temperature of 38° C. The results were as follows:

Experiment.	Solvent.	Duration in Days.	Solution in Percentage.		
			Lead.	Antimony.	Arsenic.
1	HCl 0.25 %	5	0.033	trace	trace
2	HCl 0.25 %	14	1.1	0.02	trace
3	Olive oil	6	0.628	trace	trace
4	Olive oil	14	2.0	0.57	trace

From these experiments we learn that more antimony than arsenic was dissolved, and that the amount of antimony dissolved was proportional to the length of exposure; also that, high as a solvent dilute hydrochloric acid may be for lead, olive oil is even higher. Lewin submitted similar pieces of shrapnel to the action of weak alkaline solutions—for example, 0.05 per cent. to 0.2 per cent. of soda—but, even after fourteen days' exposure, the amounts of antimony varied from 0.007 to 0.013 mg., while the amount of arsenic remained at 0.0002. From these experiments we may take it that, so far as the retention of shrapnel in the body is concerned, no damage is to be apprehended from arsenic and antimony. The one danger is lead.

NOTES ON PAINLESS CHILDBIRTH.

(HYOSCINE (SCOPOLAMINE) AND MORPHINE.)

BY

W. A. POTTS, M.A. M.D.,

PHYSICIAN TO THE BIRMINGHAM MATERNITY HOSPITAL.

ALTHOUGH several papers have been published in this country on the satisfactory and safe use of scopolamine and morphine in labour, further records appear desirable. An account of those cases in a consecutive series which illustrate the chief points will be more useful than an abstract treatise. I will therefore state the facts and give illustrations from a first series of 60 consecutive cases, 30 conducted in hospital, and 30 in private practice, most of the latter being in a nursing home. If the series were extended and the first cases excluded, I could show better results, but my chief object is to point out the pitfalls and possible dangers. The technique was modelled on that of Gauss of Freiburg.

Illustrative Cases.

The two following cases indicate the possibilities and technique:

CASE I.

Primipara, with a small round pelvis. In consultation it was decided that a normal delivery at term was possible.

The patient was awakened at 2 a.m. the day before term by sharp pains; although unable to sleep she did not send till 9 a.m. as subsequent pains were slight and at long intervals; there was not much suffering during the day, but at 9 p.m. the pains became severe. At 10 p.m. morphine $\frac{1}{2}$ gr. and hyoscine $\frac{1}{16}$ gr. were injected, the os then being the size of a two-shilling piece. The ears were plugged with cotton-wool soaked in oil, the room darkened, and the patient put on her side in bed. In twenty minutes she was sleeping quietly, and continued to do so till 1.35 a.m.; the fetal heart being satisfactory, at 1.45 a.m. hyoscine $\frac{1}{16}$ gr. was given, and a drink of water. At 5.30 a.m. the patient was again rousing; the membranes ruptured and the os was found to be fully dilated, so a third dose of hyoscine $\frac{1}{16}$ gr. was injected. At 8 a.m. a little chloroform was given by a colleague and the child delivered with forceps at 8.20 a.m. The patient did not wake till 10 a.m., when she found by feeling her abdomen that the baby was born. She said she felt no pain after the first injection.

CASE II.

Multipara. The patient was brought by her husband: she was not enthusiastic, looking on the treatment as an unnecessary fuss and expense.

Labour began at 2.30 p.m., when the os admitted two fingers; at 2.40 p.m. morphine $\frac{1}{2}$ gr. and hyoscine $\frac{1}{16}$ gr. were given; accessory treatment as usual. The patient lay on her side and went to sleep almost immediately; at 5.30 p.m. she moved for the first time, sat up in bed, and asked for a drink of water; she at once went to sleep again; at 6.45 p.m. the second dose (hyoscine $\frac{1}{16}$ gr.) was given; she was soon asleep, and the nurse thought all pains stopped; she woke up once and had another drink of water. The third dose (hyoscine $\frac{1}{16}$ gr.) was given at 11 p.m. She again went to sleep; fifty minutes later the nurse noticed her moving; she looked and found the head crowning, the baby being born before any one else could be summoned, the nurse describing it as being born with only one pain.

This patient (Case II) was subsequently most enthusiastic about the treatment. The case shows that the effect is not due to any psychological impression on the patient.

It must not be assumed that all cases will be so simple and satisfactory; occasionally the patient is restless; slight degrees can be dealt with by a few whiffs of chloroform; when severe the condition is due to faulty technique, either not giving the patient water to drink or excessive doses of hyoscine, as the following record shows.

CASE III.

Primipara. Pelvis contracted, the external measurements being: Interspinous, 9 in.; intercrystal, 10 in.; external conjugate, 7 in.

Severe pains began at 4 a.m.; at 4.15 a.m. morphine $\frac{1}{2}$ gr. and hyoscine $\frac{1}{16}$ gr. were given. The patient was soon asleep. Doses of hyoscine $\frac{1}{16}$ gr. were given at 5.30 a.m., 9.30 a.m., and 12.15 p.m. At 4 p.m., as the patient was becoming conscious and there was no prospect of delivery for some hours, another dose of morphine $\frac{1}{2}$ gr. was given with hyoscine $\frac{1}{16}$ gr.; at 7.30, and again at 10.15 p.m., hyoscine $\frac{1}{16}$ gr. was given. I was then obliged to leave, so left a further dose of hyoscine $\frac{1}{16}$ gr. to be given if necessary. Shortly after the patient woke and became very restless. The nurse, thinking this was due to an insufficient dose, injected another hyoscine $\frac{1}{16}$ gr. at 11 p.m., the eighth dose, without applying the memory test. The restlessness increased, and in a short time the patient was so noisy and unmanageable that I was summoned. I found her delirious;

three nurses were struggling to keep her in bed. With more rational treatment she became quieter, but was uneasy and restless for a couple of hours; she refused to drink any water; her pulse and general condition were satisfactory. Chloroform was given at intervals, but large quantities were necessary to produce any effect. At 1.30 a.m. she asked for a drink, and took three-quarters of a pint of water; this greatly improved her condition. At 2.30 a.m., in a lucid interval, she was persuaded to drink three-quarters of a pint of weak tea. This caused further improvement, and there was little trouble afterwards, though the pains continued to be very strong. During some of the time it was impossible to keep the patient in bed when pains occurred, yet she was so much under the influence of the drug that the instant a pain was over she would go to sleep standing up with one hand on the bed-post and snore loudly. By 4 a.m. she was quiet. The baby was born naturally at 7.30 a.m., the head being tremendously moulded. Morphine $\frac{1}{2}$ gr. was given, and the patient slept till 11 a.m.

When she awoke she had no idea the baby was born, did not know what day it was, said she had felt no pain, and remembered nothing of her labour. She was exhausted for several hours, being the only patient in the whole series who was so. On the second day she was quite well, and made an uninterrupted recovery.

The baby was not asphyxiated, chiefly because all the difficulty had been at the brim, and there had been little if any compression in the cavity of the pelvis. Such compression is a far more potent factor for asphyxia than repeated doses of the drug, provided proper precautions are taken.

In this case two mistakes were made, one being too early repetition of a dose of hyoscine, and the other not giving the patient water to drink.

It is unusual for the mother's pulse to be affected by the drug; the following case, however, caused some anxiety.

CASE IV.

Multipara. Abnormally susceptible to drugs. Five minutes after the first injection at 7.45 p.m. (morphine $\frac{1}{2}$ gr. and hyoscine $\frac{1}{100}$ gr.) she became excited, and said she felt as if she was having gas, and was choking. Three minutes later she was quiet, but said the room was swinging round and she was sinking. Her pulse was feeble and only 40. She kept asking if her heart would stop, because she felt as if it would. There was no alternative but to turn up the light and examine her. As her colour and general condition were good, and she had behaved in much the same way during her first labour, when given chloroform, for which she had begged, I turned the light down and let matters proceed. She soon became quiet, but never appeared to be much under the influence of the drug; hyoscine $\frac{1}{100}$ gr. was given at 10.30 p.m., at 11.40 p.m., and at 1 a.m.; the third dose seemed ineffective, though the fourth produced more result. The patient was apparently conscious when the child was born at 1.45 a.m., but was kept quiet and almost in the dark; she went to sleep while being washed, and slept for six hours.

I was afraid this was not a satisfactory case, but the patient's account put a different complexion on it. She said she had read about twilight sleep and thought the description too good to be true, but in her opinion it was even better.

The following case shows the chief cause of failure, starting too late, and also shows that the drugs do not necessarily diminish the uterine contractions.

CASE V.

Multipara. Pains began at 3.15 p.m. when the waters broke, but the patient did not come to the nursing home till 6 p.m. Pains were then frequent and severe; at 6.20 p.m. the os was only one-third dilated and hard; morphine $\frac{1}{2}$ gr. and hyoscine $\frac{1}{100}$ gr. were injected at 6.30 p.m.; the pains were fast and furious; half an hour later hyoscine $\frac{1}{100}$ gr. was given and the pains became even more frequent and stronger. The child was born at 7.20 p.m.; the placenta quickly followed, and there was some continuous haemorrhage; this clearly came from a lacerated cervix, as the uterus was almost in a state of tonic contraction, so I plugged the uterus with iodoform gauze. The patient made an uninterrupted recovery, and went home on the twelfth day.

This patient's consciousness was but little affected, so this was classified as an unsuccessful case. The child was not asphyxiated.

The following case also shows that labour is not necessarily slowed.

CASE VI.

Multipara. Pains began at 2.30 a.m. At 4 a.m. the os was two-thirds dilated, but the head high up; morphine $\frac{1}{2}$ gr. and hyoscine $\frac{1}{100}$ gr. were injected. The patient went to sleep immediately, but awoke at 4.35 a.m. when the pains were strong and frequent. Chloroform was given and the baby, not asphyxiated, was born at 4.50 a.m. There was no haemorrhage; the patient slept for five hours afterwards and said her labour had been painless.

In both these cases only a minimum dose of morphine ($\frac{1}{2}$ gr.) was given; possibly this was a reason why the hyoscine intensified the uterine contractions.

I have already quoted one case (Case III) illustrating the value of the drugs in the minor degrees of pelvic contraction. Another is worth recording:

CASE VII.

Primipara. Pelvis contracted, the external measurements being: Interspinal, 9 in.; intercrural, 10 in.; external conjugate, 7 $\frac{1}{2}$ in. On previous examination I thought labour at term possible; when she came into the nursing home three days before term the position was transverse, and it looked as if Caesarean section would be necessary. In consultation arrangements were made for a further examination the next morning and for proceeding to Caesarean section if necessary.

Labour began at 6 p.m. the same evening; at 9.50 p.m. morphine $\frac{1}{2}$ gr. was given and hyoscine $\frac{1}{100}$ gr., and another dose of hyoscine $\frac{1}{100}$ gr. at 2 a.m. The patient slept till 10 a.m. At 10.30 a.m. chloroform was given and the opinion formed that labour could be finished naturally. After the examination the patient was allowed to become conscious; she sat up and had dinner. At 2.30 p.m. the pains became severe, so morphine $\frac{1}{2}$ gr. and hyoscine $\frac{1}{100}$ gr. were given; subsequent doses of hyoscine $\frac{1}{100}$ gr. were given at 6.30 p.m., at 11 p.m., at 1 a.m., at 3.45 a.m., and at 5.45 a.m. Altogether eight injections were given, morphine being in two of them. The pains were strong and frequent, but the patient was never conscious. At 7.30 a.m. the patient was rousing; the head had passed through the brim and the os was fully dilated; a little chloroform was given at intervals; at 8.55 a.m. 1 c.c.m. of pituitrin was injected. The child was born fifteen minutes later with strong pains, the vagina and perineum being lacerated. After suturing, morphine $\frac{1}{2}$ gr. was given. The patient slept for four hours; when she awoke she had no idea the child was born, nor what time it was, nor what day it was.

The patient said that she had felt no pain after the first injection, except for a short time after dinner on the second day of labour. She was surprised to hear she had had a long and difficult labour. She had a morbid temperature subsequently owing to slight endometritis, but went home quite well on the twelfth day. The baby was not asphyxiated at birth; it weighed 8 lb. The fact that the baby was not asphyxiated in either this case or Case III, in both of which eight injections were given, shows that the risk does not depend on the length of labour nor the number of doses, but on other factors, including faulty technique.

The next case illustrates how small the dose should be in some cases, and the danger of a routine method of treatment.

CASE VIII.

Primipara. Premature rupture of membranes.

At 9 a.m. I found the membranes had ruptured, but the os was only slightly dilated. Pains were not severe during the day, but at night there was a good deal of suffering and no tendency to sleep, so morphine $\frac{1}{2}$ gr. and hyoscine $\frac{1}{100}$ gr. were injected at 10 p.m. The patient soon went to sleep, and slept heavily for nine hours. The next day the pains were never severe, so no treatment was necessary, the patient sleeping a little at night. On the morning of the third day pains were severe, so morphine $\frac{1}{2}$ gr. and hyoscine $\frac{1}{100}$ gr. were given at 9 a.m. Subsequent doses of hyoscine $\frac{1}{100}$ gr. were given at 12.30 p.m., 3.20 p.m., 6 p.m., 8.20 p.m., and at 10.30 p.m.; altogether six doses were given in the third day of labour. The child was delivered with forceps at midnight; it was not asphyxiated. The patient remained asleep an hour longer; when she woke up she thought it was 9 a.m., and said she had felt no pain that day.

Amnesia: The Memory Test.

The object of treatment is to produce, not analgesia, but amnesia (loss of memory for recent events). It should begin as soon after labour has started as there is real suffering. It is not advisable to administer a dose within two hours of delivery, so a little chloroform, or chloroform and ether, may be required in the final stages. Absolute quiet in a darkened room is essential, no one but the necessary attendants being admitted; the patient must not be encouraged to talk, but reasonable questions should be answered. The patient must be treated as if under a general anaesthetic, the catheter being used if necessary. The medical attendant ought not to leave; under no circumstances should he go, unless he can be quickly recalled by telephone. Close supervision is required. The fetal heart must be examined before each dose, but frequent examinations are not desirable. On two occasions immediate delivery was indicated by slowing of the fetal heart, but in both the child was saved.

Till considerable experience has been obtained, no dose after the second must be given without the use of Gauss's memory test; the patient is shown some well-known object, such as a feeding bottle or a stethoscope, and half an hour later shown the same object and asked if she has seen it before; if she cannot remember she is still so far

under that a further dose is dangerous. With experience, however, I found like several others that I can gauge whether the patient is under or not by noticing her demeanour and attitude and conversation. This is easy if a few minutes after one has conversed with the patient she turns to the nurse and asks if the doctor has come yet this morning. The patient never required a second dose who, when asked if she had had any pains since I left the room, said, "Oh, I don't know; have I, nurse?" Another patient who had been under treatment for twenty hours and had repeated injections, settled the question of an additional dose by saying, "Oh, doctor, the pains are beginning to get a little sharp; you will begin the twilight sleep soon, won't you, and not make the mistake of leaving it till it is too late."

At first some failures in relieving pain are all but inevitable; with increased experience success may be assured. Time, however, is essential; many go under in twenty minutes or less and never require another dose; others require two or three doses, or even a little whiff of chloroform after the third dose. More than three hours, therefore, may elapse before the patient is under. Partly for this reason, and partly because the worst cases of asphyxia occur if the child is born within a few hours of the administration of morphine, it is not wise to carry out the treatment unless the patient presents herself not less than four hours before delivery may be expected.

In illustration of my contention that failure to relieve suffering is due to faulty technique, I may state that of the thirty hospital cases only three were unsuccessful, and two of those occurred in the first three of the series; the first was due to too small an initial dose, which was not repeated; another was due to beginning too late. In the thirty private cases, which I did not begin till after I had had several in hospital, four were unsuccessful in that they got but little relief; three of these occurred in the first four; two of them might be called partial successes, especially as one was so satisfied that she returned for the same treatment. As illustrating the value of improved technique I may say that although her second labour was as long as the first, and she only had the same quantities of the drugs, yet she said she never felt any pain from the time of the first injection. The two complete failures were due to beginning too late, the patient having been in labour several hours and being nearer delivery than I estimated.

It is sometimes said that the use of scopolamine-morphine necessitates more frequent employment of forceps; in the thirty private cases forceps were applied ten times—not a big percentage—as it is my custom to terminate labour with as little delay as possible, and several patients came because they had contracted pelvis, and had had difficult labours previously. In the thirty hospital cases forceps were applied six times.

In the hospital cases labour was very long—twenty-four and a half hours on the average; this is not the effect of the drugs, as most were primiparae, and many had already been many hours in labour before they came under treatment. It is to be explained by the fact that in a hospital where patients are admitted only after labour has begun, few, if any, cases of easy labour are available for treatment. In the private cases, where treatment could be started at the beginning of labour, the average time was 22.6 hours for primiparae and 7.2 for multiparae; this does not differ much from the average, especially if allowance is made for the fact that rapid cases of labour are necessarily excluded.

Summary and Conclusions.

The great bugbear is an asphyxiated or stillborn baby; in the absence of an obstetric abnormality which would with any treatment have produced the condition, faulty technique is to blame. In the series of thirty private cases seven babies showed some degree of asphyxia; four of those occurred in the first seven; the three others presented only a mild degree (oligopnoea) and two of these occurred with contracted pelvis. In the first of the asphyxiated cases forceps were required; the next was a small child more than two months premature, while the mother of the third had had phthisis and a previous miscarriage, and in this pregnancy had suffered from severe tachycardia. In the series of thirty hospital cases there were six cases of asphyxia; three of them occurred in

the first eight. In addition to the thirteen cases of asphyxia in the whole sixty, four were stillborn; only one of these occurred in the private cases; as the fetus was macerated and only one dose had been given four hours before birth, the drugs were not to blame. The three others were hospital cases of contracted pelvis who ought to have been treated by induction or Caesarean section, but only came into hospital after being examined outside and after being in labour for many hours. In one, forceps having been applied unsuccessfully both before and after admission to hospital, version was performed, but the aftercoming head had to be perforated. In the second, a primipara, the child was born after more than seventy hours of labour; only one dose was given, and this was not responsible for the delay, but the facts that the child weighed 8 lb. and the diagonal conjugate measured only 3½ in. The third was a breech case in a multipara; labour lasted for thirty-four hours, there being great delay in the extraction of the aftercoming head. These facts, and the further facts that several cases had pelvic contraction, while one was a face case, one an occipito-posterior persistent lasting twenty-one hours and delivered by forceps, one a twin labour lasting sixty-three hours, both babies being born alive and not asphyxiated, one a rigid cervix treated by version forty hours after labour began, and another a rigid cervix treated by dilatation and the introduction of a Champetier de Ribes bag, labour lasting seventy-seven and a half hours, show that the fetal mortality is not increased. In two cases forceps had to be used owing to slowing of the fetal heart; both babies were saved.

Some patients had only one dose, but most a larger number; three had eight injections and one nine, the average number being 2.8 in hospital cases and 3.13 in private practice. Several patients slept continuously, others slept in the intervals, waking when pains occurred, but remembering nothing afterwards. One patient said the baby was not hers, as hers was still unborn, the house-surgeon having given her an injection which had stopped everything! In the thirty hospital cases three had morbid temperatures, but two of these had been examined before admission. In the thirty private cases only one (Case vii) had a morbid temperature. Two patients, one in hospital and one in private, had some *post-partum* haemorrhage, for which the uterus was plugged. One hospital patient was peculiar for two days after treatment; her husband said she was of a very excitable nature. All the patients did well afterwards, and all were able to go home in fourteen days. All the babies were satisfactory.

The drugs are powerful and treatment must not be lightly undertaken, but with experience, care, and close supervision the treatment does not involve any risk other than those inherent in labour itself. The relief of suffering is an enormous gain, but an even greater advantage is that, owing to the elimination of all nervous shock and exhaustion, patients are well when they wake, and present a marked contrast to those women who have gone through in the ordinary way. The close supervision and control of the patient in bed reduces the risk of infection, and enables all emergencies to be promptly dealt with. The diminished fetal mortality and morbidity of the mother shown in all statistics of cases treated on Gauss's lines follow as a matter of course.

OBSERVATIONS ON PAINLESS CHILDBIRTH.

WITH NOTES OF FIFTY CONSECUTIVE CASES TREATED
BY THE HYOSCINE (SCOPOLAMINE) AND
MORPHINE METHOD.

BY

MARGARET VIVIAN, L.M.S.S.A.,
BOURNEMOUTH.

So much has been written both for and against the use of the hyoscine (scopolamine) and morphine method in labour that a brief account of fifty consecutive cases in which the treatment was successfully administered may be of interest.

Dosage.—When the scopolamine-morphine method first came into prominence in this country we were told that, in order to ensure success, it was essential for the practitioner to remain in attendance throughout the labour.

Careful observation was said to be necessary to determine the dosage, and numerous elaborate tests were given for ascertaining whether the patient were in the required state of semi-narcosis. If it were true that the practitioner could not safely leave the bedside, this fact would in itself constitute an insuperable objection to the employment of the method in a very large number of cases. There are very few practitioners, especially in war time, who could devote so much time to each maternity case, and, even if they could do so, the fee would necessarily be prohibitive in the great majority of cases. Moreover, a method that demands such close observation suggests an undesirable element of danger.

In my first cases I strictly obeyed this rule, never leaving the bedside after the administration of the first injection. By keeping a careful record of the dosage, I soon came to the conclusion, however, that as good results could be obtained by adhering to a fixed dose, which need be varied only under abnormal conditions such as individual idiosyncrasy, or unduly prolonged labour due to uterine inertia, or any other cause.

My experience has taught me that the best results are obtained by means of a large initial dose administered as soon as the pains are strong and regular, followed by a small dose at intervals of two hours. One must use one's judgement as to the right moment for beginning the treatment, the size of the dose not being a reliable criterion.

My first injection consists of omnopon $\frac{1}{2}$ gr., with scopolamine $\frac{1}{100}$ gr., and within ten minutes of its administration the patient is almost invariably sound asleep, her mind remaining a blank until the confinement is over. The exceptions, which in my experience amount to about 6 per cent. of the cases, are those women who, probably owing to some personal idiosyncrasy, are apparently not susceptible to the drug. Though their faces are flushed and their pupils enlarged, they remain wide awake, and will subsequently state that they felt the pains with undiminished severity.

The second and subsequent injections consist of scopolamine $\frac{1}{100}$ gr., administered at two-hourly intervals, provided the pains continue to be strong and regular. If the pains cease, the injections are suspended until the pains resume their proper course. In primiparae, if the os is dilating very slowly and the pains occur only at long intervals, say every half or three-quarters of an hour, the scopolamine injections should be given every three or four hours only. In many cases I have given ten injections in all. In one case I gave fifteen, and in another sixteen, without any injurious results either to the mother or baby. The largest total amount of scopolamine was one-tenth of a grain, and the baby was not even sleepy when it came into the world.

It is, of course, undeniable that some babies are affected by the drug, and a few of them have caused me some anxiety, owing to their "blueness" and reluctance to breathe. In no single case, however, has a baby failed to respond to artificial respiration, hot and cold baths, etc., and I am of opinion that this condition of oligopnoea, though alarming to the uninitiated, is not really dangerous. I have entirely failed to find any connexion between oligopnoea in the infant and the amount of the drug administered to the mother: the worst cases occurred when only four or five injections had been given, while in the prolonged cases I have mentioned, in which fifteen and sixteen injections were given, the infants showed no signs of poisoning. It has been stated that if the opium or morphine is repeated after the first injection, the baby will be born "blue," and this would no doubt be the case if opium were given with each injection. In some prolonged cases, when a patient has become very restless, I have, however, added morphine $\frac{1}{4}$ gr. to one of the intermediate injections without in any way adversely affecting the baby.

By adopting the above-mentioned routine for the injections, the latter can safely be left to a trained nurse in an ordinary straightforward case, and the doctor, having given the first injection, will not be required until the head is showing. The confinement need not, therefore, occupy any more of the doctor's time than an ordinary case, and one of the chief objections to the method thus falls to the ground.

Duration of Labour.

It has been stated that labour is greatly prolonged, but I have found this to be the case only in a very minor

degree. The patient, being semiconscious, cannot of course help herself by bearing down, as a fully conscious patient can, and for this reason the labour is perhaps slightly prolonged. This disadvantage is, however, more than balanced by the advantage arising to the patient from the absence of shock.

One doctor told me that in every case in which he had attempted the method the labour pains had ceased immediately after the first injection, and he had consequently been forced to discontinue the treatment. I cannot, however, believe that he was correct in thinking that the cessation of the pains was due to the injection. How often has one not observed a temporary cessation of the pains in an ordinary labour where no injections have been given!

Of the fifty cases in which I have used the method, thirty have been perfectly successful; the patient has slept quietly throughout the labour, a slight change in the breathing being the only outward manifestation of the uterine contractions. Fourteen patients were restless and noisy, complaining loudly of each pain, and struggling violently during the actual birth. The next day, however, they remembered nothing, and showed no signs of exhaustion. Three cases were a complete failure, and the remaining three were multiparae, whose confinements were so rapid that there was time for only one injection in each case.

The Patient's Surroundings.

It is often stated that the method can be properly administered only in a nursing home or hospital and should never be attempted in the patient's own home. This is true to some extent, although in a private house, where perfect quiet can be obtained, together with the services of a competent nurse, there is no reason why the treatment should not be as successful as in a nursing home. It is of course absolutely essential that the patient should be kept perfectly quiet; the room should be darkened and the nurse should wear soft slippers and be careful to avoid all unnecessary disturbance of the patient. If the house is in a noisy street it is advisable to deaden the sounds by putting a little cotton-wool in the patient's ears. After the confinement, the nurse must wash the infant in another room and discourage conversation on the mother's part. If allowed to talk she will possibly recall isolated incidents, and may even fancy that she remembers the whole process of labour. Provided the baby is removed at once, and the mother kept perfectly quiet in a darkened room, the latter usually sleeps for several hours and remembers nothing on waking. If the patient seems restless and excited, I sometimes give an injection of morphine hydrochloride gr. $\frac{1}{4}$ after the conclusion of labour.

Of the fifty babies, forty-nine are alive and well, the exception being premature and stillborn. Nine were born "blue," but of these only three caused me any anxiety. In four cases forceps were necessary, and these were the only patients to whom a little chloroform was administered, more as a measure of precaution than from any real necessity.

The effects of the drugs pass off rapidly; in a few cases the patients' pupils were dilated the next day, and some of the mothers complained of being very thirsty. There is one precaution which must never be neglected—that of passing a catheter at regular intervals if the labour lasts more than eight hours. If this is not done the labour is likely to be considerably retarded.

The drugs used for the injections were Hoffmann-La Roche's omnopon ampoules and Parke Davis's scopolamine tablets.

AN illustrated pamphlet, entitled, "Britain's greatest need," has been issued by Dr. Barnardo's homes pointing out the importance to the empire of securing that, so far as possible, every child born within its limits shall be brought to man's estate. For fifty years Dr. Barnardo's homes have been doing the work which has been so urged upon us during the war. In that time the homes have taken charge of 84,000 children, and 10,264 Barnardo boys are now serving in defence of their country. Since war broke out Dr. Barnardo's homes have admitted 5,033 boys and girls, and with increased support many more could be taken. Gifts of all kinds—money, food, clothing, blankets, etc.—will be welcomed by the honorary director, Mr. William Baker, M.A., LL.B., at head quarters, 18 to 26, Stepney Causeway, London, E.1.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A MODIFICATION OF CARREL'S TUBE FOR USE ESPECIALLY WHERE THERE IS DANGER OF PRESSURE ON TISSUES.

War surgery, more than any other surgery, has demonstrated the amount of damage that drainage tubes cause to tissues owing to the devitalizing effect of continuous pressure; and the larger, thicker, and more closely fitting the tube, the greater is the superficial pressure necrosis. The detrimental effect on tissues, together with the small advantage gained over other methods of drainage, has resulted in their disuse to a great extent.

There is one condition, however, in which some form of tube is necessary for the conducting and distributing of fluids to parts of a wound—that is, in the "Carrel-Dakin" treatment. Even the small and moderately thin-walled Carrel's tube is not infrequently instrumental in causing some superficial pressure necrosis.

A small perforated tube of rubber, like a diminutive colotomy tube, would not be liable to cause such damage. Such a tube not being available I used, with satisfactory results, a finger, or part of a finger, of a rubber glove, perforated freely with small holes, tied on to a small tube, and made secure by a stitch through both finger and tube. When such a tube was placed in a wound by the side of a Carrel's tube, the bed where the glove finger had lain showed little or no tissue damage, while the Carrel's tube frequently caused a gutter with a grey surface.

Modification of Carrel's tube. The holes in the glove finger may be made either with the points of fine scissors or with a fine punch.

The finger part of such a tube can be placed against an exposed vessel, nerve, or brain substance with the minimum amount of damage to these tissues.

One advantage of some considerable importance is that the tube rarely becomes blocked with exudation from the wound surface, a disadvantage which is fairly common when Carrel's tubes are used.

Some months ago I first made use of this arrangement, which has proved very satisfactory, both in my own unit and in other casualty clearing stations.

H. DRIFFIELD LEVICK, B.S., F.R.C.S.,
Captain R.A.M.C.(T.F.).

A CASE OF MELÆNA NEONATORUM SUCCESSFULLY TREATED BY THE INJECTION OF BLOOD SERUM.

THE following notes may prove interesting as adding another successful case to the series of three recorded by Dr. Robert Hutchison in the *BRITISH MEDICAL JOURNAL* of November 10th, 1917:

A male child was born at 3 p.m. on March 19th, 1913. The mother was a primipara, and delivery was by forceps. At 8 a.m., on March 22nd, it was noticed that there had been a large hæmorrhage from the bowel. The blood was liquid and very dark. Treatment was by calcium chloride and gelatin, but the hæmorrhage continued all day. At 9 p.m., as the child was evidently sinking, the father was bled from the arm, and 10 c.cm. of blood serum were injected under the skin of the child's abdomen. The hæmorrhage never recurred. Unfortunately the child suffered from a congenital heart affection, from which he died at the age of twelve months.

Dr. Hutchison suggests that normal horse serum or antidiphtheritic serum would probably prove as efficacious as human serum. In the only case of hæmorrhage in which I have tried it—that of a hæmophilic boy with a small wound of the tongue—the former proved inefficacious, and the patient bled to death.

London, S.E.

ALEX. ROSE, M.D.

Reports of Societies.

SERUM DISEASE FOLLOWING INTRATHECAL INJECTIONS.

At a meeting of the Section of Medicine of the Royal Society of Medicine held on November 27th, the Vice-President, Surgeon-General H. D. ROLLESTON, R.N., who was in the chair, read a paper comparing the manifestations of serum disease after the intrathecal and after the hypodermic method of injection. Speaking of meningism due to serum disease, he said that injection of serum into a healthy intrathecal space set up an aseptic chemical meningitis, whereas injection of antineurococcic serum in cerebro spinal fever reduced the inflammatory process, presumably by destroying the meningococci. It had been pointed out by Neal, Abramson, and others, that injection of serum into slightly inflamed meninges set up in most cases an acute aseptic meningitis shown clinically by fever, rigidity of the neck, and other signs of meningeal irritation. It was desirable to have some means of determining whether there was a genuine relapse which would be benefited by serum, or whether the condition was one of meningeal irritation or meningism and a manifestation of serum disease which might be intensified by a further injection of serum. The diagnosis could be made by examination of the cerebro-spinal fluid for the presence of meningococci, and also for the normal reducing agent (glucose) which was absent in relapses of meningitis and present in the meningism due to serum disease. This meningeal manifestation of serum disease was peculiar to intrathecal injections of serum. It did not appear to result from large quantities of serum given, nor could it be explained as due to an intrathecal injection within a very few days of the appearance of the serum rash, but was probably connected with some hypersensitiveness of the meninges. It did not appear to be proved that the incidence of serum disease was higher after intrathecal than after the hypodermic method of injection. Intrathecal injection of serum necessarily involved risk of inducing increased intracranial pressure and might introduce a secondary infection; but it was not proved that the volume of serum injection favoured a secondary infection of the meninges from the blood stream.

Dr. CLAUDE B. KER gave an account of a series of 60 cases treated with Flexner's serum. Of 48 patients who lived nine days or over, 36, or 76 per cent., suffered from serum sickness. The outstanding feature was the rash; arthritis was noted in 6 cases only, and in these was very severe. Adenitis of the cervical glands was present in 2 cases. An interesting point was the occurrence in 9 cases of prodromal fever for twelve or twenty-four hours before any other symptoms. More than a third of the total reactions commenced on the ninth day. In 19 cases the rash was troublesome for four days or over, and in 3 it lasted for fully eight days. It was now well understood that the introduction of horse serum into the spinal canal was liable to set up a local reaction, which might be described as an aseptic meningitis, so that the possibility of a fluid becoming more turbid from this cause must be remembered, and in the absence of germs it was probably wise not to take an increase of turbidity too seriously. The great number of rashes might suggest that intrathecal injection was more liable to cause them than the subcutaneous method, but he did not believe that this was the case. It was not unusual to find that the use of certain consignments of horse serum was followed by the appearance of an unusually large number of rashes, and it was generally admitted that the blood of some horses was more irritating than that of others. He thought that this might be the explanation of the large number of reactions following the use of this particular serum of Flexner's. His records did not show that the occurrence of the rash was much influenced by the dosage. He thought these attacks of serum sickness were of advantage rather than otherwise, many cerebro-spinal patients being much improved by these reactions. The benefit was probably due to some stimulation of metabolism and the processes of repair. The Fehling test was a useful means of determining whether a rise of temperature, with an exacerbation of meningeal symptoms, was caused by a reaction or by a recrudescence of the disease.

Lieut.-Colonel E. W. GOODALL said that prodromal fever had been noticed after the subcutaneous injection of serum. Fever might occur without a rash. The proportion of rashes varied with the serum used. No doubt, if the patients who died during the latent period were excluded, 40 per cent. of the remainder would have had rashes. The severity of serum sickness was not nearly as bad as when serum was first introduced.

Dr. J. D. ROLLESTON thought that the severity of the rashes was determined by the size of the dose and varied indirectly to the severity of the attack.

Major C. R. Box drew attention to the absence of rashes when precipitated antitoxin was used. Numbers of men in the army had been injected with tetanus antitoxin and might get cerebro-spinal fever later. What was the likelihood of anaphylaxis occurring in such men? He thought that the percentage of rashes might be linked up with the amount of foreign protein given. Figures from two general hospitals showed that the rashes only amounted to 2 to 5 per cent. of the cases injected, and might be due to the small amount of protein administered as the unitage was high.

Lieut.-Colonel GOODALL said that the strength of unitage had gone up, but the volume to be injected had gone up also. Many soldiers had frequent injections of antitoxin, but the number who got anaphylaxis was very small.

Dr. R. A. O'BRIEN also spoke, and Surgeon-General ROLLESTON briefly replied.

Reviews.

CLINICAL TUBERCULOSIS.

THE world-wide campaign against the ravages of tuberculosis has now been in progress for many years. The results that have hitherto been obtained can be examined by the light of experience, and a comprehensive treatise on the whole subject, written by one who has had the fullest opportunities for observation and study, must be welcomed. Such a treatise, contained in two portly volumes, has recently been presented, under the title *Clinical Tuberculosis*,¹ by Dr. F. MARION POTTENGER, the Director of the Sanatorium in Southern California which bears his name.

A very large number of patients, suffering from tuberculosis in many forms and stages, have of necessity passed through his hands, and in his work he has had able assistance from highly qualified colleagues who have added to the value of the book by their own contributions upon special departments. With the feeling that in times past there has been too great a tendency to rely upon laboratory findings and pathological theories founded upon them, Dr. Pottenger has endeavoured to approach the subject from the clinical side, to study to understand the symptomatology, and to correlate it with pathological findings. His practice has brought him into contact with tuberculosis of the lungs more than with the disease as affecting other organs, but he emphasizes the fact all through his work that local disease in any part of the body must of necessity have some effect upon the function, if not the structure, of other parts and organs, and that these effects are part of the malady that has to be treated.

Although every aspect of a very wide subject comes in for review, the author disclaims any pretensions to the production of a general textbook. He has brought together a series of essays and monographs in which each subject is critically examined. This arrangement of necessity leads to a good deal of overlapping and repetition, but such repetition applies mainly to essential points, and serves to emphasize cardinal facts upon which special stress should be laid. Among these may be instanced the infection of lymphatic structures at early periods of attack. The actual point of entry of the bacillus into the human system in any individual case can never be determined. The first indications are almost always observed in lymphatic tissues. In young persons this is especially manifest, as in them the bacillus has a virgin soil for development, not yet protected in any way

by previous infections. The detention of the bacillus in the lymphatic structure is immediately followed by the formation of protective substances, and the fact is well known to all who have had experience of tuberculosis as a life-long disease, that early glandular infection appears to exercise prophylactic effects, even in cases where it has advanced to suppuration. Hence Dr. Pottenger is averse to the removal of lymphatic glands or of tonsils when affected by tubercle, unless they are causing obstruction.

In reviewing so comprehensive a book as this, it is only possible to refer to a few of the main points. Amongst these we may instance the discussion on the relative frequency of bovine tuberculosis, which he considers to be negligible after the age of 10 and only present in young children in a comparatively small proportion. Clinically the two types are indistinguishable and the diagnosis must always be made in the laboratory. Infection by way of the tonsils or through the mucous lining of the intestines is first delayed in its passage through the lymphatic glands or channels. In such organs as the liver, the kidneys, or the spleen the secondary metastases, which may occur if the infection passes the glandular filter, are not at first indicated by symptoms, and in the lung such infection must have produced a good deal of local disturbance before any physical evidence of its presence can be obtained. In the meninges, on the other hand, the disease is very quickly indicated. The proclivity of the apex of the lung in young adults to tuberculosis is explained by the fact that during the years of growth the gradual change of shape in the thoracic cage leads to stagnation of circulation through the upper parts of the lungs. Hence the bacilli passing through them become arrested, whereas in children, where the circulation is much the same through all parts of the pulmonary area, there is no such tendency to apical disease. Diagnosis of present disease by all the usual methods is adequately described, but the value of the x-ray evidence is not estimated quite so highly as by many of its advocates in this country.

The effects produced by the tuberculous poison upon the nervous system are so various and complicated that no definite scheme of cause and effect can be formulated. The author is led to the conclusion that the disturbance of the normal balance between the vagus and the sympathetic is the most obvious phenomenon, and this in turn opens up an endless vista of speculation. The organic and mental results of such disturbance, and the formation of auto-genous toxæmic substances and their effects, are dealt with at considerable length. Due regard is paid to Head's observations on the relation between local tenderness and visceral disease.

The second of the two large volumes is devoted to the subjects of treatment and of complications. In many respects Dr. Pottenger's views and consequent practice differ from those of many other clinicians, but he states very clearly the grounds upon which such difference is founded and fully recognizes that there may be several roads to success. To aid natural processes, rather than to attempt to neutralize the effects of the tuberculous poison by outside means, is the main idea that he inculcates. Hence he considers that tuberculin, in common with other remedies, should only be used with that object and not with the view of direct attack. Of climatic treatment, as such, he speaks with considerable reserve, and deprecates over-confidence in its powers.

Throughout the many chapters in which he describes the numerous aspects of his subject, Dr. Pottenger keeps an open mind and makes it clear that successful results are best to be obtained by careful and continuous study of the individual, coupled with experience of the disease as occurring in like cases. His own experience is recorded within the covers of a work that deserves cordial recognition, not only as a full and comprehensive account of the disease as it appears to the clinician, but as embodying the mature thoughts and opinions of an accomplished clinical observer.

RADIOGRAPHY.

THE second edition of ROBERT KNOX's book on *Radiography and Radio-Therapeutics*² has followed in less than two years after the first. In reviewing the first edition we

¹ *Clinical Tuberculosis*. By Francis Marion Pottenger, A.M., M.D., LL.D., Medical Director Pottenger Sanatorium for Diseases of the Lungs and Throat, Monrovia, California, etc. London: Henry Kimpton, 1917. (Med. 8vo; 2 vols.; pp. 707 and 713; illustrated. £3 3s. net.)

² *Radiography and Radio-Therapeutics*. By Robert Knox, M.D. Second edition; first volume, Radiography. London: A. and C. Black, Ltd. 1917. (Sup. roy. 8vo, pp. xxv + 384; 490 illustrations. 30s. net.)

expressed the opinion that it was by far the best book on the subjects in the English language; we see no reason to alter this opinion. The present edition has been so much enlarged that the book is now in two volumes: the first—the one now under review—dealing with radiography; the second—which will appear later—with radio-therapeutics. The present first volume is now as large as the original book, some 150 pages having been added, with a number of new illustrations. The general construction has been adhered to, the first 130 pages dealing with the instrumentation of radiography and a full description of various types of tubes, including the Coolidge and hydrogen tubes. A short account of the installations necessary and suitable for military service has been added to this section. An interesting account is given of the apparatus for the production of single-impulse radiographs, and two very fine examples of the stomach and bowel after an opaque meal show the possibilities of this method of plate production.

The chapter on photographic technique is clear and concise and does not enter into unnecessary detail of what, after all, is a very simple process. Following this is a chapter on stereoscopic radiography, and then a comprehensive account of the localization of foreign bodies, in which all the principal useful methods are fully dealt with. This is a valuable addition to the book, as this subject was not treated of in full in the first edition. There is a short account of radiography as an aid to the surgeon and physician in war time, with special reference to gas gangrene. An important, and sometimes overlooked, part of radiography follows—namely, the radiography of normal bones and joints, the feature of this chapter being the description of the skull and accessory sinuses, with special reference to the technique. Very remarkable negative and positive pictures of the antero-posterior view of the living human skull are striking evidence of what is possible in this direction. Chapters on the injuries of bones and joints, diseases of bone, differential x-ray diagnosis in diseases of bones and joints, follow in sequence, and then very full accounts are given of the examination of the thorax and its contents, the examination of the alimentary system, and the radiography of the urinary tract.

The illustrations are a valuable feature of the whole book. They are all of superfine excellence and are well chosen to visualize the letterpress description. Side by side are reproduced the negative and the print from the negative, and the contrast between the two is distinctly educational from the point of view of the reading of radiographs. Although many of these reproductions are quite small, it is remarkable how the various points are brought out, and we congratulate the author on the care which has evidently been exercised in making the blocks and in printing from the same.

The general arrangement of the contents is admirable, and the simplicity of the writing renders it an easy matter to follow the descriptions of the author. When one considers the scope of radiography at the present time, and the enormous number of conditions in which it can render diagnostic aid, it is remarkable that so much concise and clear information can be given in one volume; it does not appear that a single point has been overlooked.

Whilst this volume should appeal to every one even remotely interested in radiography and its possibilities, it is especially adapted for the use of the student. It should be read not only by the student and qualified man who is seriously taking up the study of radiography from a professional point of view, but also by every medical student before he or she qualifies. Radiography has now become of great importance from a diagnostic point of view in both medicine and surgery, and a book of this kind emphasizes this in an unmistakable manner.

NOTES ON BOOKS.

THE four large volumes of Dr. H. M. HURD's *Institutional Care of the Insane in the United States and Canada*,^{*} a monumental work, give a detailed historical account of what has been done for the mentally afflicted in North America from the earliest days. The history of each of

^{*}The *Institutional Care of the Insane in the United States and Canada*. By Henry M. Hurd, William F. Drewry, Richard Dewey, Charles W. Pilgrim, G. Alder Blumer, and T. J. W. Burgess. Edited by Henry M. Hurd. Baltimore, Md.: The Johns Hopkins Press. 1917. (Med. 8vo. Four volumes; illustrated.)

the many institutions and asylums is given, and photographs of the present buildings are in many cases added. Lists of the past officers are included, and there are many biographies, often with portraits, of eminent North American alienists. Dr. Hurd is to be congratulated upon the success with which he has carried out the collection and colligation of the numerous interesting records contained in these volumes. Naturally they will appeal most strongly to readers across the Atlantic; but in their record and analysis of success and failure in attacking a problem of great importance in all civilized communities—namely, the care of the insane—they should find many readers throughout the world.

VOLUNTARY FOOD RATIONS FOR CHILDREN.

THE Food Ministry, when issuing the new voluntary rations three weeks ago (November 17th, p. 656), laid stress on the fact that children were not rationed. It has now considered it advisable to issue the following suggestions for average weekly rations for children. It recognizes that the needs of individual children differ greatly, and that some children may require a more liberal provision, while others may need less. It is strongly advised that boys and girls whose food is rationed should be weighed every fourteen days at the same period of the day before a meal, and a record kept of their weight without clothes; if the weights are stationary or decline after two consecutive weighings, the allowance of food should be increased.

Voluntary Rations for Children and Young People.

Ages.	Bread.	Other Cereals.	Meat.	Butter, Margarine, etc.	Sugar.
	lb. oz.	oz.	lb. oz.	oz.	oz.
Boys and girls: 0-5	3 0	6	1 0	6	8
6-8	3 8	8	1 8	8	8
9-12	4 8	10	2 0	10	8
Boys: 13-18	6 0	12	2 0	10	8
Girls: 13-18	5 0	10	2 0	10	8

The explanations as to the meaning attached to the various terms, "bread," "other cereals," "meat," etc., are the same as those which apply to adult rations printed in the JOURNAL at the page mentioned.

The Food Controller is also issuing the following suggestions with regard to the quantities of other foods which should, on the average, be supplied weekly to boys and girls whose consumption of bread, cereals, meat, and sugar is rationed in accordance with the above table:

Ages.	Potatoes.	Other Vegetables.	Milk.	Cheese.	Eggs or Equivalent.	Fish.	Jam and Syrup.	Cocoa Equivalent.
	lb.	lb. oz.	pts.	oz.		oz.	oz.	oz.
Boys and girls: 0-5	3	0 8	2	—	2 only	—	12	—
6-8	4	1 0	2	1	2 ..	—	12	1
9-12	5	1 0	2	1	2 ..	8	12	1
Boys: 13-18	7	2 0	2	2	3 ..	12	12	1
Girls: 13-18	5	1 0	2	1	2 ..	12	12	1

If any article of food should not be procurable, an equivalent in some other form should be supplied, and the following list of the quantities of different foods approximately equal in food value is given:

Milk	1 pint	Potatoes	1 lb.
Eggs	5 only	Other vegetables	2½ ..
Fish	1½ lb.	Jam	6 oz.
Cereals	2 ..	Cocoa	3 ..
Meat	4½ oz.	Bread	5 ..
Cheese	3½ ..		

We propose next week to publish a short study of the value of these rations with reference to the special conditions of nutrition in growing children.

British Medical Journal.

SATURDAY, DECEMBER 8TH, 1917.

THE FOOD POSITION.

THE responsibility of the medical profession is second only to that of the Government with respect to the formation of correct opinions upon the food problem, and we therefore make no apology for returning to this very serious subject. We said last week that the relation between work performance and energy requisite in the food was not a subject for rhetoric, but was capable of precise evaluation. It seems desirable to illustrate this by concrete examples. Unfortunately, the value of medical and physiological research in industry has only been recognized within a very recent period, so that data directly relevant to the problem are not numerous; sufficient, however, exist for the immediate purpose.

Concordant and relatively numerous observations show that for subjects who are neither very thin nor excessively obese the heat production while at rest in the recumbent posture is approximately 1 calorie per kilo of body weight and hour. In Benedict and Cathcart's series¹ their subject (a track cyclist) produced on the average 1.17 calories a minute when at rest on a couch; as the subject weighed 65.9 kilos, this works out at 1.06 calories per kilo and hour. Some unpublished observations we have seen upon a lighter man physically untrained give a slightly higher rate—namely, 1.18 calories per kilo and hour, but the experiments were less numerous and accurate; we may fairly take 1 calorie as a reasonable minimum, allowing for diminished metabolism during sleep. When the subject is not recumbent, but sitting up, although not performing measurable external work, the heat production increases. In Benedict and Cathcart's observations the increase was about 15 per cent.; with the untrained subject to whom we referred, the increase on passing from bed to sitting at a desk was as much as 30 per cent. We may provisionally assume an increase of 25 per cent. for sitting as compared with lying in bed.

The energy transformation during industrial work has been studied by Amar² using the Zuntz and Schumburg technique. His subject was a metal-filer working at the rate of 70 strokes of the file a minute. The man was a skilled operative, 38 years old, weighing 74 kilos; it was found that he did work equivalent to 20.8 calories (that is, nearly 8,840 kilogram-metres of work) per hour and liberated 290.5 calories per hour (inclusive of the thermal equivalent of the work). Hence, if he worked eight hours at this rate, slept eight hours, and rested or lounged the remaining eight hours, we should reach a total heat liberation of 3,656 calories. In an earlier monograph³ Amar reported some observations on twenty-seven Algerian labourers working moderately hard for four to six hours daily on a stationary bicycle. We have analysed these data, and the deduced formula connecting heat, work, and body weight gives for a man doing the same amount of work and of the

same weight as the metal-filer 3,327 calories daily. As the work of the Algerians was simpler and more easily measurable the concordance of the two results is as close as can be expected. From an estimate of the work performed by ordinary metal-filers, which Amar put at about 61,500 kilogram-metres in a day of eight and a half hours, the above calculation, which allows 70,720 kilogram-metres, surpasses the average. Hence it would not be unfair to assume that the 3,656 calories actually liberated or transformed by the body might be replaced by the calories in food *as eaten* when we take an average medium worker. Thus we reach a necessary ration for the moderate muscular worker of not less than 3,500 calories. Amar reckons the performance of severe work, such as that of a smith, at double the metal-filer's output. This is determined not from statistics of diets, which might, in theory, go beyond real energy needs owing to personal or national predilections; but from direct measurement of the physiological facts: It is further to be noted that our estimate is a minimum, since we assumed for the whole eight hours of the resting period of the day a rate of output which is in strictness only applicable to persons quietly sitting down. Owing to poor transport facilities industrial workers often have to walk quite long distances to and from the factory, and this exercise evidently demands more than $1\frac{1}{2}$ calories per kilo and hour. Benedict and Cathcart have provided ample and accurate data for very severe work on a bicycle ergometer, but it is evident that much more research is desirable to establish the precise quantitative relations of energy intake and work production for light work. If the medical profession instil into the public mind even the facts just recited they will have accomplished a salutary task.

In the current number of the *National Food Journal*, the official organ of the Ministry of Food, what is described as a stirring letter to Mr. Hoover from Lord Rhondda is reproduced. This letter contains the following passage: "To my own fellow countrymen I say quite frankly that what we ask of them in food economy is scarcely worthy the name of sacrifice. If those who continue to live and stay in comparative comfort at home (air raids do not really disturb the daily routine) are not willing to deprive themselves of quite unessential foods, then our bravest men have died in vain." This is finely phrased, but what is the real position from the scientific standpoint, that is to say, in the light of cold facts? It is demonstrable, and demonstrated, that the moderate worker needs 3,500 calories in the food to be able to perform his task. It is demonstrated in Dr. Hill's memorandum that our munition workers have on the average not much exceeded this ration but have, by rhetorical appeals and gaudy advertisements, been encouraged to change their normal habits of consumption from a mainly cereal to a largely animal diet. During the last weeks the Food Ministry has proposed to all workers, strenuous and sedentary alike, a way of living which leaves them to cover a heavy deficit of necessary energy from various articles, chiefly bulky vegetables, which are not evenly distributed through the country. Some of the officers of the Food Ministry may even have seen the long queues of shabbily dressed women and children waiting outside provision shops, shops which speedily set out the now familiar notice, "No butter, no margarine, no tea." We submit that these conditions cannot appropriately be termed "scarcely worthy the name of sacrifice," and that the phrase will become still less applicable before many months are over.

² *Le moteur humain*. Paris, 1914, p. 527.

³ *Le rendement de la machine humaine*. Paris, 1910.

When such statements as these appear in official journals, it is not strange that the lay press has sometimes failed to grasp the real bearings of the situation. In the course of an article urging immediate resort to compulsory rations, the *Evening News* (December 1st) remarked: "The people want to feel that they are all sharing alike, and till they do the bulk of them will refuse to economize in order that a certain number may eat more than their share." The writer of these lines ingenuously supposes first that "the people" will be satisfied if food is equally divided among the population; and secondly, that a proportion of "the people," sufficiently large to diminish sensibly the available supply of foodstuffs, habitually overeat. But this is not true.

The scientific basis of the whole matter, that food if apportioned at all must be apportioned in strict accordance with the energy transformations demanded by different kinds of muscular work, is ignored in such utterances. It is not hard to forecast the danger which confronts this nation.

Bearing in mind the many precedents which this war has created, we may safely assume that the problem of compulsorily rationing a nation is now engaging the attention of a committee, and may consider it highly probable that this committee consists of some permanent civil servants, some more or less successful men of affairs who are civil servants *pro hac vice*, and a small minority of unofficial medical men. A classification will be made on paper, the public will be assured that it conforms to the requirements of scientific knowledge, there will be angry protests, recriminations, modifications, and muddle, with steadily increasing exasperation and superficially inexplicable strikes. We have no panacea for these evils, and believe that any compulsory system of rationing must, as pointed out by Mr. Underhill in his excellent letter in the *Times* of November 30th, lead to injustices and inequalities, but we think that the evils might be mitigated by an appropriate choice of expedients.

In our judgement the rationing authority should consist, not of professional or amateur civil servants with a small leaven of medical men, but of representative members of the medical profession, including physiologists, with a small number of persons familiar with the conditions of our great industries as assessors. Such a committee would have the inestimable advantage of perceiving what points needed fresh investigation, and of knowing where to obtain any needed assistance; with the help of factory experts it would be able to decide how far the conclusions deducible from existing data might be applied to particular classes of labour, and, in doubtful cases, could arrange for the carrying out of special tests. The technique of metabolism experiments on the lines of Zuntz, Benedict and Cathcart, and others, is less difficult than might be supposed, and it is perfectly practicable even in these times to extend such observations as those of Amar to important but so far unstudied classes of labour. A strong medical committee would not only secure the services of the right men but would know where these are to be found, which a lay body cannot be expected to do. The Royal Society's Food Committee, with the addition of representatives of clinical medicine, would fulfil many of the requirements we deem essential, but in that event it must no longer be an advisory body which the officials of the various Government departments concerned may ignore if they choose, but the paramount rationing authority, with full powers to engage such a staff and carry out such inquiries as are found necessary.

We are under no illusions in this matter, and have little doubt that nothing short of great public pressure will induce the Ministry of Food to deviate from the course followed by nearly all Government departments—namely, to pay eloquent tribute to the importance of science in words and to ignore it in deeds. No such pressure of public opinion at present exists; there is merely widespread discontent and uneasiness, which may be diverted into attacks upon "profiteers" or "food hogs" by one section of the press or demands for some unspecified form of "drastic action" by another. The medical profession must educate the public so that the essential elements of the problem are grasped, and we shall endeavour to furnish them with such aid in this great work as it is in our power to provide.

WAR NEPHRITIS.

THERE is room for discussion whether some of the diseases brought prominently into notice by war conditions are absolutely new, or are only affections which, rare in ordinary times, have become common in the altered circumstances of camps and exposure to unaccustomed conditions. Some, such as spirochaetal jaundice, are old, though our knowledge of them has been perfected since 1914, and their increased frequency has now made them matters of common knowledge. In other instances the question cannot really be settled until their causation is established. This applies to war nephritis, which Sir John Rose Bradford¹ cautiously remarked belongs to a type "at any rate not common in civil life," while Dr. Mackenzie Wallis² spoke of it as much commoner in war than in peace, as shown by the records of the American Civil War. The clinical manifestations are remarkable, and may be said to constitute a new syndrome. Intense dyspnoea is a special feature, and the question arises as to its relation to acidosis, for in renal disease dyspnoea may be caused by acidosis due to phosphate retention and not to accumulation of acetone bodies. For this inquiry, which should be made in the acute stage seen abroad, there have so far been few opportunities in this country; out of five cases investigated, three by Dr. Langdon Brown³ did not show acidosis. From the minute study made by Captains Shaw Dunn and J. W. McNee (p. 745), it appears that the morbid changes also present special features, clearly shown in the beautiful coloured drawings by Sergeant A. K. Maxwell reproduced to illustrate their paper. Various factors have been suggested, such as severe climatic conditions, mineral poisons, chlorinization of the drinking water, excessive protein dietary, intestinal toxæmia, direct bacterial infection (pyelonephritis), bacteria in the blood or urine, and septic foci elsewhere in the body; but all these factors seem to have been excluded, and until the causal factor has been determined it will be wise to suspend judgement before finally deciding that war nephritis is a new disease.

Dr. Mackenzie Wallis, from experiments on animals, arrived at the conclusion that in the early stage the urine contained an ultra-microscopic organism which he considered might be the cause of the ill effects produced in animals by injection of the urine. Captains Shaw Dunn and McNee obtained negative results from examination of the organs for bacterial and spirochaetal infection; streptococci found in the urine of some cases were also present in control catheter

² Mackenzie Wallis: *Journ. Roy. Army Corps*, London, 1916, xxv, 259.

³ W. Langdon Brown, *ibid.*, 1915, xxv, 75.

specimens from men not suffering from nephritis, and so could not be regarded as of any importance, and blood cultures from forty acute cases remained sterile, even after prolonged incubation. There is therefore no evidence in favour of the view, rather widely expressed but resting on vague reasons, that the condition is infective.

Some points in the etiology of the disease are worth consideration. Officers very seldom suffer, the Indian troops in 1915 and civilians living in the war zone escaped, and no influence can be attributed to season, weather, or locality. It accordingly appears that war nephritis is connected with some special circumstance of the active soldier's life, and this deduction is to some extent supported by the incidence of the cases in small groups. A fresh point is that the dyspnoea is associated with a morbid change in the lung not corresponding histologically with any usual form of pneumonia or bronchopneumonia, but resembling the lesion due to inhalation of an irritant gas. The epithelium of the bronchi is desquamated, there is much leucocytic infiltration, the terminal bronchioles and infundibula show oedematous swelling and loss of epithelium, and many of the capillaries contain hyaline thrombi. These changes appear to resemble those described in a rather fatal form of purulent bronchitis in soldiers at the front and also in the Aldershot Command, characterized by intense dyspnoea (Abrahams, Hallows, Eyre, and French⁴). The renal changes, however, were quite different, namely, toxic degeneration in the tubular epithelium (Hammond, Rolland, and Shore⁵). Cases of war nephritis terminating fatally do so within two weeks from the onset, and in thirty-five out of the forty-two necropsies there was a striking uniformity in the morbid changes. In the kidneys the only gross change is a characteristic projection of the glomeruli, as pale transparent globules on the cut surface when seen through a hand lens. Microscopically there is a universal change in the glomerular capillaries due to obstruction by endothelial cells, which, when packed together, resemble syncytium. The circulation of the blood through the capillaries is so impeded that diminution in the urinary output might naturally be expected, but this does not hold good. Though spoken of as a diffuse intracapillary form of glomerulitis, there is a remarkable absence of the definite acute inflammatory changes so common in acute glomerular nephritis. The renal tubules contain blood which may be derived from the glomeruli. This diffuse change in the glomeruli forms a contrast to the patchy glomerular changes due to minute emboli in subacute bacterial endocarditis, and suggests that the capillary changes are due not to gross material emboli, but to some poison which from its chemical characters is suitable, like water, for excretion by the glomerular tufts, and the ingenious view is propounded that the glomeruli are picked out because they are specialized for the excretion of water. The changes in the lungs, as already mentioned, are compatible with the view of inhalation of irritant gases, and, in cases of chlorine gassing, extensive inflammation of the renal glomeruli has been described. Further, in both gassing and war nephritis miliary haemorrhages may occur in the brain. But as there is no evidence of gassing in any of the cases, it is possible that a blood-borne irritant has been excreted with the oedematous fluid into the bronchioles and infundibula. On this supposition the lung lesions might be secondary to those in the kidney, or the changes in both organs might be due to the same poison.

Thus, although the cause has not yet been determined, Captains Shaw Dunn, and McNea have, by a process of inductive reasoning based on the data amassed by their careful research, arrived at the conclusion that war nephritis is due to the selective action of an unknown poison on the glomerular capillaries. In connexion with the possibility of metallic poisoning, Sir Thomas Oliver (p. 755) instituted a careful investigation. Analyses by Mr. T. M. Clague showed the absence of lead from the cooking pans and drinking water conveyed in cleansed petrol tins at the front, and the presence of infinitesimal traces of lead in the bully beef and Maconachie ration. On the other hand, lead was found in the urine nine times in twenty-nine samples of urine from soldiers in the Northumberland War Hospital, and it was shown that bullets or shrapnel retained in the body may give rise to lead and albumin in the urine. The last observation is of considerable interest, but it is not of course suggested that this explains war nephritis. Irresponsible speculation is perhaps gratuitous in the face of such careful work, which, however, by limiting the cause to some circumstance special to the soldier's life, tempts the reader to wonder if from the shell-riven and corpse-saturated soil of the Western front some complex organic poison may in certain conditions contaminate the food or drink of those who are attacked by war nephritis.

EXPERT OPINION ON THE SANATORIUM TREATMENT OF TUBERCULOSIS.

THE recent discussion at the Medical Society of London has served to indicate the considered opinions of a large number of physicians and others who have had long practical experience in dealing with tuberculosis. That sanatorium treatment has not as yet fulfilled the expectations entertained when it was instituted has long since been obvious to every one. Neither the general case incidence nor the death-rate have been materially affected.

Reports from all sanatoriums contain records of a large number of early cases in which the disease has been arrested, but they also show that a great many persons have been under treatment without receiving anything more than temporary benefit, and that although life has been prolonged for a while, it has not been rendered useful to the community, the end being at the best postponed for a very few years.

It would thus appear that sanatorium treatment, if it is to fulfil the claims originally set up for it, must be utilized in accordance with the experience gained. If it be indeed the best means that we possess for restoring the consumptive to economic usefulness, why should it still be used for temporary repair of the economically useless? Other means for such repair are available, and the continued use of sanatorium treatment for other than incipient cases is hardly to be justified. It has been fully demonstrated that the available accommodation falls very far short of requirement and that under the present system only a very small proportion of such accommodation as there is can be said to be yielding the results for which it was provided. Greater discrimination is manifestly called for to distinguish between the curable case, needing long residence, the incipient case for which instruction only is necessary, during a short stay, and the cases which show no tendency to improvement and which should give place to the other classes when the nature of the malady is recognized.

⁴ Abrahams, Hallows, Eyre, and French, *Lancet*, 1917, ii, 377.

⁵ Hammond, Rolland, and Shore, *ibid.*, 1917, ii, 41.

Apart from the sanatorium question, upon which most speakers appear to have been agreed, the larger problem of environment was discussed, and although the part played by infectivity was fully recognized, its relative importance was not as uniformly accepted. While accepting the so-called massive infection as an ever-present danger, many authorities would appear to regard the more diluted forms of infection, to which so large a proportion of healthy persons are liable, as of minor importance unless specially favoured by unhealthy environment. As a general outcome of the discussion it would seem that sanatorium treatment from the public point of view has proved to be a failure, although it has rendered very material service to individuals.

Notification in like manner has not as yet provided the means for stemming the flowing tide of tuberculosis, but in the case of both these agents, the fault would appear to lie in the method by which they are applied. Neglect of notification is a serious fault, but neglect by public authorities to make proper use of the information it affords is another serious fault. The sanatorium should no longer be used for the patching-up of damaged lives, but should be strictly reserved for early and curable cases. For the diminution of the case incidence and the lowering of the death-rate other means must be found, since the sanatorium can no longer be regarded as efficient for these purposes.

AMERICAN HOSPITALS AND SURGEONS IN FRANCE.

The reference to the American medical units made by Sir Donald MacAlister in his presidential address to the General Medical Council calls to mind that it is not this year that members of the medical profession in the United States of America began to play a part in the war so far as the important section of it conducted by the British Expeditionary Force in France is concerned. The American Hospital outside the Neuilly gate of Paris, which at one time worked for the British as well as for the French forces, opened its doors within the first few weeks of the war; about the same time also an American motor ambulance team, which included a certain number of American medical men, also began to work, and not very many months had passed before more than one medical man of American extraction and education had successfully volunteered for service in the commissioned ranks of the Royal Army Medical Corps itself. It was also well before the first year of the war was over that a plan was working under which two university centres in the United States undertook to supply the medical staffs of not less than two base hospitals. The teams engaged to serve for not less than six months, a portion of them then returning home and being replaced by new arrivals. They were American units in the sense that the ward medical officers, surgical experts, and officers in charge of divisions, as also the officers in charge of special departments and the nurses, were drawn from the United States, while their administrative officers and the other ranks were supplied by the Royal Army Medical Corps. One of these hospitals is still at work alongside similar base hospitals more purely American in character which got to work this year. Of these there are about half a dozen, and though they bear the numbers of the British General Hospital units which they replace and whose habitations they inherited, they are all complete American units in the sense that each of them was formed in the United States as part of the general arrangements made by the American Red Cross Society in anticipation of the possible extension of the American army. At first there were only two of them, but now they are about fifty in

different parts of the United States, all raised to represent different localities or institutions. The first two units, representative of Harvard and the Western Reserve Universities, sailed for Europe within about five days of the time they actually received word from the Balfour Commission that their services would be valuable. These two first units were respectively organized by Professors Harvey Cushing and Crile, both of whom had previously in turn played a part in the affairs of the American hospital at Neuilly. The latter was for long worked on the principle that some distinguished surgeon formed his own team and brought it over ready to take charge of a section of the work for a period of three months; and the existing hospitals, to which reference has been made, seem to be constituted on the same principle, but without the time limit. All of them have been formed with the idea that when the moment comes they will step into their places as units of the medical departments of the American army, and each has at its administrative head an officer belonging to the medical corps of the standing army of the United States. The other officers, who take complete charge of the professional work, are medical officers of the Reserve Corps (M.O.R.C.), and do their work under an officer who is always a more or less well known medical man in America, and bears the title of Director. He also holds rank as a major in the American army, the other officers being commonly lieutenants and sometimes captains. In the American army, as in the French, the nominal rank of officers is commonly a grade or two lower than in our own. There are also usually attached to each of these American units in France two officers of the Royal Army Medical Corps, one of whom acts as registrar, and assists the administrative commanding officer in respect of the returns required by the British authorities, and the other as quartermaster. There are at present American registrars and quartermasters also. There are also a few R.A.M.C. of other ranks at some of these units. With these exceptions, the whole of the personnel is drawn from the United States. They work under the orders of the D.D.M.S. of the area in which they happen to be placed (they are distributed over the principal British bases in France) and enjoy the advantage of the assistance of the consulting surgeons and physicians attached to the bases concerned. Most of them seem to fly the Stars and Stripes, but otherwise there is nothing to differentiate them from the other hospital units—British, Australian, New Zealand, Canadian, and South African—serving with the British Expeditionary Force, except in respect of the uniforms of their officers, nurses, and other ranks. Nor do they differ in their internal arrangements as a whole, though they do differ materially in one important factor. They are strongly staffed on paper as compared with British hospitals of the same nominal size, and extremely strongly staffed in practice, since British hospitals in France seldom have more than about two-thirds of their official establishment strength. The United States officers in military hospitals are by no means the only American medical officers now in France. A large number of others not attached to hospitals have arrived in France during the past few months, and have been distributed among the armies at field ambulances, casualty clearing stations, and elsewhere. Whether the base units mentioned as well as the unattached medical officers will be withdrawn when the time comes for the American army to take its place in the line does not appear yet to be settled. Meantime the hospital units in particular are playing an exceedingly useful part, and the American medical officers as a whole are gaining an experience which will prove invaluable when the war for the American army really begins. Several of the American base hospitals are understood to have contributed surgical teams to the casualty clearing stations during the recent heavy fighting, and one American medical officer attached to a field ambulance is rumoured to have been recommended for the Victoria Cross.

MEDICAL STUDENTS IN THE RANKS.

THE Army Council has issued an Instruction (1751) providing that students who at the time of their enlistment (whether they enlisted voluntarily or were called up under the Military Service Acts) were actively engaged in medical studies and had completed the second year of their professional course, are, if eligible, and they so desire, to be transferred (regardless of their medical category) to Class W, or W (T) of the Reserve, or discharged if ineligible for transfer to the Reserve, for the purpose of resuming their studies with a view to obtaining a medical qualification. For the purpose of this instruction a man who had on or before enlistment completed two years of medical study, and who can within thirty-six months complete his professional curriculum and obtain his medical degree or licence, is to be regarded as a third year medical student. Students who do not pass the professional examination in anatomy and physiology within six months of resuming study will be recalled to the colours, and a student transferred to the Reserve, unless he resumes his medical studies and enrolls in an Officers' Training Corps, will be recalled. Any third year medical student who is desirous of being released from the colours under this instruction must apply through the usual channels, stating the date on which he desires to be released, and that he undertakes to resume his studies with a view to obtaining a medical qualification. A similar difficulty is being met in a different way in France. Owing to the prolongation of the war the supply of newly qualified men is drying up; casualties among medical officers have been numerous, the medical service in this respect coming next after the infantry. The French mobilization scheme provided that a medical student in a certain stage of the curriculum, reached usually at the end of the second year, should, when called up, be appointed *médecin auxiliaire*, a grade unknown in the British army, but corresponding with that of surgeon probationer in the Royal Navy, which itself is the revival of the old grade of surgeon's mate. The case of medical students who have not advanced so far has recently engaged the attention of the Ministers of War and of Education, and of the General Staff, with the result that arrangements have been made by which medical students from the ranks may attend special courses of lectures and eventually obtain credit for them when they seek a civil degree in medicine. Three schools of military medicine have been established for their benefit in regions behind the front, and have been duly provided with professors, libraries, and laboratories. Two courses of lectures are given, one for those who have completed the first year of medical studies, the other for those who have completed the second year. Each course is partly practical and partly theoretical, and will last six months. At the end of each an examination will be held and those who pass it will receive a certificate, showing that they are entitled to be recognized by the civil medical faculties as having advanced a year in their studies.

BUTTER SUBSTITUTES.

THERE is at present a great shortage of butter and margarines. The public are at the moment hardly able to get any margarine at all in many towns, and, as margarines are popularly supposed merely to differ one from another in price and palatability, any substituted fats placed on the market in bulk will command a ready sale. A word of caution on this point seems desirable. It is known that butter is particularly rich in one of the "accessory substances" necessary to healthy metabolism. Drummond and Halliburton, in a recent note,¹ have called attention to the fact that this substance is not found indifferently in all margarines. According to them, the oleo-oil margarines, which have as a basal fat an oleo-oil prepared from beef fat, can fully replace butter in the

dietary. Vegetable oil margarines, on the other hand, which are usually prepared from coco-nuts, peanuts, etc., are by no means equal to butter and the oleo-margarines in nutritive value. Apparently the fat-soluble accessory substance is present in the coco-nut fibres and absent from the expressed oil. Hence some of the vegetarian suets and lard substitutes, which are often deodorized coco-nut oil or hydrogenated cotton-seed oil preparations, are unsatisfactory. These results accentuate the importance of effectively salving animal fats, the unavoidable waste of which in small households is considerable. This again points to the desirability of organizing communal feeding, a matter which the Ministry of Food is bringing to the notice of the local Food Economy Committees. Naturally any effective organization will take time to develop, and it is important for the medical profession to be adequately represented on the local bodies, so that the primary physiological elements of the subject shall receive proper consideration.

FOOD CONTROL.

THE public does not yet seem fully to have realized the position into which this country has drifted with regard to the food supply. Its seriousness is obvious to the medical profession, and the facts put forward by the scientific advisers called in by the Government can leave no doubt upon the matter in the mind of any one who examines them. We fear, however, that they have not yet been fully faced even by the Government departments concerned. It is unfortunate that there is no single body authorized to deal with the matter in all its aspects. It is getting on now for two years since the Royal Society, at the request of the President of the Board of Trade, appointed a Committee on the Food Supply of the United Kingdom. This Committee made a series of reports—the first dated July 1st, 1916, and the last December 9th, 1916. They were presented to Parliament as a White Paper (Cd. 8241) in the first days of February, 1917. We are not aware whether the Food Ministry considers itself bound by this report made to another department, and we fear that there is some evidence that it has, at any rate, not given full attention to it. The question of the food supply is one which nearly concerns the Munitions Ministry also. Mr. Lloyd George, when at that Ministry, appointed a committee with Sir George Newman as chairman. It is a mixed committee, containing representatives of medicine and physiology, as well as of the Factory Department of the Home Office, together with Mr. J. R. Clynes, M.P., Mr. Samuel Osborn of Sheffield, and Mrs. H. J. Tennant. This committee has issued a series of most valuable memorandums. Its third, published just two years ago, dealt with the subject of industrial canteens, and one of the appendices to this—the first edition of Dr. Leonard Hill's important memorandum on the investigations of workers' food containing suggestions as to dietary—is dated July, 1916, although not published until three months later. We hope that the Food Ministry has given full attention to these memorandums, which, though they concern munition workers primarily, have an application to hand workers generally, and therefore have a direct bearing on the work of that Ministry. We do not feel quite confident that this is the case, for we note that the new edition of Dr. Hill's memorandum, revised with the assistance of Captain M. Greenwood, who before he joined the R.A.M.C. was statistician to the Lister Institute, was issued simultaneously with the Food Ministry's circular as to food rations, published in the middle of November, and the recommendations of the two documents do not tally. The Wheat Commission also has something to say in the matter inasmuch as it is the authority which controls imports. The London Corn Exchange, after hearing Sir A. Yapp, on December 3rd adopted a resolution expressing its recognition of the gravity of the food situation for the allies as a whole and of the difficulty

¹ Proceedings of the Physiological Society, *Journal of Physiology*, li. 1917, p. 8.

which would arise in this country under a system of compulsory rationing, but we seem to be drifting rapidly in this direction. What is happening with regard to sugar—the replacement of the household sugar card by individual cards—is a foretaste of the complexities from which the housekeeper may shortly be suffering. The Government departments concerned require unified advice founded on ascertained facts, scientific and commercial, in order to give the public a clearer lead.

ALBUMINURIA DUE TO SALICYLATES.

ALTHOUGH pharmacological and other textbooks mention albuminuria and haematuria as due to salicylates, this toxic result is so rarely recognized in ordinary hospital practice that it is rather surprising that Scott and Hanzlik¹ invariably found albumin, leucocytes, and cast-like bodies in the urine of sixteen persons receiving full doses (on an average a total of 210 grains in 30 grain hourly doses) of sodium salicylate. Nine of the subjects were suffering from rheumatic fever, and the other seven were normal. Possibly the large size of the hourly doses accounted for the urinary manifestations. The albuminuria was at its height when symptoms of salicylism were produced, and usually disappeared when the excretion of salicylates was finished—namely, about four days after the drug was discontinued. Hanzlik and Karsner² have continued the research by the hypodermic injection of sodium salicylate in dogs, cats, and one rabbit, with the result that albumin, leucocytes, cast-like bodies, and sometimes red blood corpuscles appeared in the urine. Albuminuria, if present before the experiment, was aggravated by it. The albuminuria is renal in origin, and microscopically there is a change in the kidney, varying from simple cloudy swelling of the epithelium of the proximal convoluted tubules to extensive cloudy swelling of all the cortical parts of the tubules associated with an acute intracapillary glomerulitis. The blood of practically all the animals showed a variable though definite accumulation of non-protein and urea nitrogen, an indication, therefore, of diminished renal functional efficiency as far as these tests are concerned.

TRANSFUSION OF WHOLE BLOOD.

PROFESSOR SIR EDWARD SCHÄFER, in a letter published elsewhere in this issue, directs attention to a research conducted by him nearly forty years ago, in which he demonstrated experimentally, on dogs and cats, the value of the transfusion of blood in cases of severe haemorrhage. He attached the vessel of the donor to that of the recipient by cannulae inserted into each vessel, connected by a piece of rubber tubing six inches long. The cannulae and tube were filled beforehand with sodium carbonate solution. It is remarkable that the suggestions made in this paper were not widely acted upon and their clinical value proved, because, in the light of our present knowledge, we feel sure the method would have been successful in the treatment of haemorrhage. The method of direct transfusion introduced and described by Crile³ is in some respects ideal. A single metal cannula is used to connect the two vessels; the severed vein of the recipient is pulled through the lumen of the cannula and then turned back like a coat sleeve over its end. The artery of the donor is then pulled over the open end of the vein which has been turned back over the cannula, and the vessels secured in this position by a ligature. When the clamps previously placed on the vessels are released, the blood must flow from donor to recipient over uninjured continuous endothelium, and does not come in contact with a foreign surface of any kind. We pointed out last week (page 695) the objections to the employment of direct as

compared with indirect transfusion. Experience has shown that the indirect method has many advantages, and the greater number of those who have had extensive experience in transfusion of blood have abandoned all direct methods.

MEDICAL CERTIFICATES FOR RECRUITS.

SIR DONALD MACALISTER, in his presidential address to the General Medical Council, which was reported in last week's SUPPLEMENT, made pointed reference to the duties of medical practitioners in connexion with certificates as to the health of men liable to military service. One case in which the Council took a grave view, though it postponed judgement, is reported in the SUPPLEMENT this week, and it appears that several instances of doubtful or irregular certification were reported by tribunals, but were not thought by the Penal Cases Committee to demand formal inquiry by the General Medical Council. The President's words made it quite plain that the vast majority of the profession are fully conscious of the obligations laid upon them by the State in this matter, but that a few practitioners still lay themselves open to suspicion by the National Service Ministry through the looseness, or irrelevance, of statements appearing over their signatures. Later in the session a suggestion was made that the President's remarks should be circulated to every practitioner, together with the familiar warning notice in regard to the giving of medical certificates, and a covering letter pointing out the need for clear discrimination between facts of which a doctor has personal knowledge and statements made to him. After a short discussion the President suggested that the National Service Ministry might itself solve the difficulty by indicating to practitioners the nature of the certificates which would alone be acceptable or helpful for its purpose, and the Council agreed to communicate with the Ministry in this sense. It is unfortunate that there would appear to be a certain number of doctors who have brought their profession into disrepute by the carelessness or bias shown in their written statements. We hope that this small minority may be brought to a higher sense of responsibility by the ventilation which the matter has now received. The difficulty is to reach them without appearing to lecture the profession as a whole on a point of elementary professional conduct.

EPSOM COLLEGE.

ONCE again we would draw our readers' attention to the financial needs of the Royal Medical Foundation of Epsom College—an institution which is linked to our profession by many ties. Epsom College was founded in 1853 by one of our number—John Porport. His object was to assist medical men by educating their sons well and economically. The College foundation, on which fifty boys are educated and maintained free of cost, is confined to the sons of medical men; beyond this there are no restrictions as to entry, and Epsom provides a first-class education for all its pupils on the lines of the great public schools of England. Created by the efforts of the medical profession, and containing always a nucleus of the sons of medical men, it is only natural that Epsom College should furnish many recruits to medicine. The association between the College and the medical profession is thus twofold. But besides training the young for the battle of life the Foundation cares for those who have fallen out of the ranks, by giving pensions to aged practitioners, or their widows, whose means are slender. In order to keep up this good work—the maintenance of fifty Foundation scholarships and of fifty pensions—an annual sum of not less than £4,500 has to be raised. In the fourth year of the war this task will be heavier than at any previous time. The question of ways and means has grown more difficult each year; for not only has the cost of living increased out of all knowledge, but the sources of revenue have shrunk through the withdrawal of many subscriptions. It would be a public

¹ R. W. Scott and P. J. Hanzlik, *Journ. Amer. Med. Assoc.*, 1916, LVIII, 1838.

² P. J. Hanzlik and H. T. Karsner, *Arch. Int. Med.*, Chicago, 1917, xix, 1016-1028.

³ *Haemorrhage and Transfusion*, 1909.

misfortune if the Council through lack of fresh support should be forced to curtail the charitable work of this excellent Foundation. We therefore commend to the notice of our readers, and especially those who have influence with the wealthier sections of the public, an appeal by Sir Henry Morris, the treasurer, which appears on page 778. We endorse this appeal with the more confidence because we have reason to know that a large number of contributions came in last year as a result of what we wrote on this subject twelve months ago. The need is now greater than ever.

TYMPANISMUS VAGOTONICUS.

UNDER this heading Professor R. Bálint¹ of Budapest has recorded three cases of a condition which he has the courage, not to say temerity, to maintain has not hitherto been understood or described. All his patients were soldiers and their most prominent symptom was tympanites. Other phenomena were bradycardia, respiratory arrhythmia, excessive urinary excretion of water, sodium chloride and nitrogen, eosinophilia, Graefe's sign, excessive perspiration and hyperacidity of the gastric juice. The administration of atropine transformed the whole condition in less than an hour. The tympanites vanished, the collapse of the abdomen being accompanied by gripping pain, and the bradycardia, respiratory arrhythmia, and other symptoms either disappeared altogether or became much less prominent. The condition could be conjured up again simply by giving physostigmine. No abnormal quantity of gas could be found by the *x* rays in the stomach, and the distension was attributed to the dilatation of the intestines. One of the patients had suffered from dysentery, otherwise there was no history of typhoid fever or dysentery with which this condition could be associated, nor was it like the tympanites of typhoid fever or dysentery, which is usually associated with either diarrhoea or constipation. Professor Bálint could also find no evidence of hysteria, and he believes the condition to be a neurosis of the vagus provoked by faulty internal secretion. He suggests that this condition is not very rare, and that henceforth many cases will be recognized which have previously been misunderstood. The faulty diagnoses made to his knowledge were many and varied, including ascites, myocarditis, tuberculous peritonitis, and echinococcus of the liver. Several fruitless laparotomies were also performed.

MINISTRY OF PUBLIC HEALTH: A CONTRADICTION.

THE *Daily Express* published on Tuesday a long article in large type stating that Dr. Addison, Minister of Reconstruction, had been offered and had accepted the post of "Minister of Public Health"; the new ministry, it was said, would overshadow the Local Government Board and would aim at nothing less than the nationalization of the medical profession, involving free medical attendance for all without any element of charity, so that little of the present system of medical practice would survive except in the case of a few independent consulting physicians. This article was followed the same day by an official announcement that the assertion that Dr. Addison had been offered and accepted the post of Minister of Public Health was unauthorized and incorrect, no question having arisen of his leaving his present post. "His only personal concern with the question of the establishment of a Ministry of Health has been that, as Minister of Reconstruction, he is giving assistance in the negotiations for arriving at an agreed scheme for the establishment of the Ministry. At the present stage no question as to the policy of the Ministry of Health has been raised. As was pointed out by Dr. Addison, in a recent speech on the subject, the question of the policy to be pursued and the developments to be undertaken could only be effectively

considered by the Government in consultation with those concerned after the establishment of the Ministry of Health. It would obviously be impossible at the present time, when so many doctors are serving with the armies in the field or with the Home Forces, to consider any scheme which, in the words of the announcement that has appeared in the press, would throw the whole medical system of the country in the melting-pot."

THE constitution of the special Shock Investigation Committee, of which Professor E. H. Starling, F.R.S., is chairman, is stated at p. 772. The Committee will, we understand, be glad to receive information as to clinical studies or experimental observations on the subject. Communications should be addressed to Dr. H. H. Dale, F.R.S., secretary of the special Committee, at the Medical Research Committee, 15, Buckingham Street, Strand, W.C.2.

Medical Notes in Parliament.

The Appointment of Medical Boards: Method of Determination.—In reply to Mr. Needham, Sir Auckland Geddes said that members of medical boards were appointed by the Chief Commissioner of Medical Services on the authority of the Minister of National Service. The boards were composed of civilian medical practitioners drawn from a panel set up in the area of each board from medical practitioners whose names had been suggested by the Local Medical War Committee. The chairman of each board, who was the Deputy Commissioner of Medical Services of this Ministry for an area, arranged with the Local Medical War Committee a roster of attendances of members at sessions of his board. A board of four required a panel of eight to twelve members; the nominations reached the Ministry through the Central Medical War Committee; they were reviewed in the medical department of the Ministry by the Chief Commissioner of Medical Services, were made by the Minister, and notified to the Deputy Commissioner of the area.

Medical Volunteer Corps.—In reply to Sir William Collins, Mr. Macpherson said that sixteen county medical volunteer corps had been formed or were in process of formation, and that the total number of field ambulances provided by these corps was twenty-nine. No medical volunteer corps had yet been formed in the county of London, but it might be possible to use the services of certain personnel in London if proposals under consideration matured.

Inoculation in the Navy.—In reply to Mr. Dundas White, Dr. Macnamara said that inoculation was not compulsory in the Royal Navy. Certain consequences, however, ensued from refusal on the part of any individual to be inoculated against infectious disease. In particular such individuals were debarred from landing in ports where there might be any danger of contracting any disease against which inoculation was regarded by the Admiralty as advisable.

Neurasthenic Soldiers.—Mr. King asked Mr. Macpherson what was the result of the promised consideration of the question of sending back to the front soldiers who had suffered from neurasthenia. Mr. Macpherson replied that the question had been discussed with the expert advisers, and the proposal was to classify neurasthenics on discharge from hospital in groups representing the periods during which they should not serve again in the firing line.

Nerve Strain in Soldiers (Ireland).—In reply to Mr. King, Sir A. Griffith-Boscawen said that he did not agree that there was an undue proportion of medical men holding positions connected with lunacy on the Irish Medical Board which dealt with soldiers disabled for uncertifiable nerve strain. He added that Dr. McKisack, physician to the Royal Victoria Hospital, Belfast, who was in no way connected with lunacy, had been appointed president of the board in succession to the late Dr. Graham. He also stated that it was not practicable to give consideration to the opinion of a man's own doctor at the time of discharge from the army, but in case of re-examination it was always the practice to give full consideration to such opinions as well as to the representations of the local committees.

DR. A. J. RICE-OWLEY has been re-elected chairman of the Public Health Committee of the Council of the Royal Borough of Kensington.

¹ *Berl. klin. Wochs.*, April 30th, 1917.

THE WAR.

SHOCK: ITS NATURE, PREVENTION, AND TREATMENT.

So much has been done by scientific investigations and clinical work to bring under control the infections of gunshot wounds, that at the present time the military surgeon's chief preoccupation is the prevention and treatment of shock. It must have caused much anxiety during the Cambrai offensive, and the more recent severe fighting to meet the German counter-attacks. The majority of the wounds in the open fighting seem to have been bullet wounds, which, as is well known, heal with rapidity, and are much less dangerous than shell wounds. The weather, when it became wet, was not so wet as during many previous offensives, and all the correspondents have commented on the joy of walking over turf. The relative dryness of the ground must have been very favourable to the wounded, and we hear, indeed, that cases of gas gangrene have been rare. But the weather all through has been cold, and cold is the great enemy of a seriously wounded man suffering from shock. There seems to be no doubt that the first advance of General Byng's army was a surprise to the enemy. Owing to the decision to dispense with an intensive preliminary bombardment the number of guns which had to be moved into the area beforehand may not have been large, but many tanks, which are neither invisible nor silently moving objects, had to be brought up, and the medical preparations were necessarily on a large scale. As on previous occasions, they must have included the temporary enlargement of casualty clearing stations, involving additional operating teams and increased personnel generally, as well as the pushing forward of advanced operating stations. The speed with which the casualties were brought in and the condition in which they reached base and home hospitals proves that the medical arrangements worked very successfully, despite the quickness with which they had to be made.

We have on several occasions described the working of the resuscitation wards, which are now a feature of every up-country hospital and casualty clearing station. Continual improvements are being made. From quite an early stage of the war, as our readers know, attempts to prevent the onset of shock or limit its depth have been made. Hot drinks were provided for serious cases at the regimental aid posts and advanced dressing stations, and food and hot coffee at places on the roads and paths likely to be traversed by walking cases, as well as at the main dressing stations, which the wounded, whether lying or sitting, eventually reach. Among the motives underlying the constant endeavour to increase the rapidity with which wounded are collected and transferred to casualty clearing stations and up-country hospitals, this hope of preventing shock has been one of the chief. As we stated eighteen months ago, it had then become the practice to provide hot-water bottles in ambulances, and the later plan of warming motor ambulances by bringing the exhaust air from the cylinders through ambulance bodies, illustrated in the *JOURNAL* of August 18th, 1917, p. 224, has been found efficient as well as economical. The resuscitation ward is a very valuable part of the equipment of casualty clearing stations, and something of the same kind—a shock tent or shock ward—appears now to be a common feature of main dressing stations as well as of advanced dressing stations, when the subterranean character of most of the latter makes it possible to provide them. The temperature of the atmosphere of such wards or tents is raised by hot air, or each stretcher is warmed by converting it, when on its trestles, into a hot air chamber; in this way the stretcher and its occupant are kept warm while dressings or splints are being reapplied, or the patient's wet clothing removed. We have described the provision for warming-up patients by electric heaters, which, if necessary, can be made the equivalent of an electric light bath.

The prevention of shock has long been one of the leading aims of front line work; the value of the measures adopted has been thoroughly established, and a further stimulus to their systematic employment has been given by scientific researches into the physiological phenomena of shock. The researches have confirmed the opinion reached on clinical grounds, that the view commonly held, to the

effect that shock is in some way connected with a great draining of blood into the splanchnic area—that, in fact, a patient, in the picturesque phrase, bled into his abdominal vessels—is erroneous. Operations on the abdomen in cases of well-marked shock do not reveal any undue amount of blood in the abdominal viscera.

The result of the laboratory work summarized in the memorandum on surgical shock and allied conditions issued by the Medical Research Committee, and published in the *JOURNAL* of March 24th, tended to show that the concentration of the blood observed in shock is due to a widening of the whole capillary area of the viscera and musculature with an outpouring of plasma into the tissues. Active contractility of the capillaries has frequently been described and important evidence of its existence has recently been provided. There is some reason to believe that, so far from the smaller arteries losing tone in shock, they are constricted. In discussing the treatment of shock, the memorandum mentioned that pituitary extract, by causing a prolonged and general contraction of the arterioles, and thereby diminishing the total capacity of the circulatory system, mitigated the effects of deficient blood volume. The failure of injections of physiological saline in fully developed shock is known; the memorandum contained a suggestion that better results might be obtained by intravenous injections of hypertonic saline, and it was noted that calcium ions have a specific action in reducing abnormal permeability of capillaries.

Professor Bayliss explained his views on the importance of the factor of viscosity in solutions used to replace blood lost by haemorrhage, and the possible value of gum solutions, in a letter published in the *JOURNAL* of April 28th, 1917, p. 564. The results of his experimental inquiry, reported to the Royal Society last year in a paper on methods of raising a low arterial pressure,¹ may best be given in his own summary:

When the arterial pressure is low from loss of blood it cannot be brought back, except to a certain degree, by the injection of saline solution in volume equal to that of the blood lost. But if the viscosity of such solutions is raised to that of the blood, a return to normal height is possible.

The effect of saline injections is also much less lasting than that of solutions containing gum or gelatin. The difference in this case is due to the osmotic pressure of the colloids, by which loss of water by the kidneys and to the tissues is prevented. Solutions containing gum do not produce oedema in artificial perfusion of organs.

When the fall of blood pressure is due to peripheral vasodilatation, gum or gelatin solutions, although more effective than pure saline, produce a much less permanent rise than in cases of loss of blood. No signs of heart failure could be detected and the cause of the fall of the raised pressure to its original height is still obscure. The combination of a small dose of barium chloride, as recommended by Langley, with a moderate amount of gum solution, was found to be the most satisfactory method in such cases, and no diminution of vaso-motor excitability resulted.

The view that fall of arterial pressure produces peripheral vaso-constriction by means of nervous channels and that rise of arterial pressure produces vaso-dilatation was confirmed by artificial perfusion of a limb.

At the request of the Medical Research Committee Professor Bayliss last August visited various centres in France, to discuss with workers there special problems in the field and the application to them of methods devised in the laboratory. Acting upon suggestions made to it from France the Committee appointed a Special Investigation Committee for the purposes of further combined study of shock and the better correlation of laboratory and clinical observations. This committee consists of Professor F. A. Bainbridge, Professor W. M. Bayliss, F.R.S., Professor W. B. Cannon, Dr. H. H. Dale, F.R.S. (secretary), Lieut.-Colonel T. R. Elliott, F.R.S., R.A.M.C., Captain John Fraser, R.A.M.C., Professor C. S. Sherrington, F.R.S., Professor E. H. Starling, F.R.S. (chairman), and Colonel Cuthbert Wallace, C.B. Professor Cannon, whose own work in this connexion is of great value, has been good enough to make arrangements for co-ordinating the work of this committee with that of a similar committee of American physiologists, and we understand that a further memorandum on the subject will probably be issued before long.

In a paper in a recent issue of the *Archives Médicales Belges* Professor Bayliss stated that the physiological requirements of colloidal osmotic pressure and viscosity, can be met by the employment of a fluid containing 2 per

¹ *Proceedings of the Royal Society, B*, vol. XXIX, p. 380.

cent. of gum arabic, and that as this solution does not contain any protein there is no risk of anaphylaxis in the event of a second transfusion being necessary. He stated in his letter to the JOURNAL that he had established this point by experiments on animals. The solution of gum, by increasing the viscosity, enforces the peripheral resistance, and so raises the blood pressure, and the calcium salts contained in the gum exert their vaso-constrictor effect.

As much shelter, warmth, and comfort as possible should be provided for shock cases at the most advanced medical posts. A great deal has been heard of the extensive use of concrete by the Germans not only for making "pill boxes" and reinforcing trenches, but also for sheltering dressing stations near the advanced lines. Many visitors to the British front are aware that the British army also has advanced dressing stations built of concrete. They were, we believe, constructed almost solely by officers and men of the R.A.M.C. brought in from field ambulances and other units. The establishment of a medical unit under canvas is carried out by its own personnel, which lays out the site, erects the tents, establishes latrines, and lays out paths, doing a little gardening in spare time, but in many cases medical units themselves erect huts by their own exertions, almost without engineering assistance. The assistance of engineers becomes necessary when general hospitals and large stationary hospitals have to be huddled as rapidly as possible, their sites underdrained, communications with main roads established, and the supply of electric light as well as water arranged. In the selection of the site of a hospital its accessibility to a railway for receiving and evacuating patients must always be the main consideration, but an ample water supply is necessary, and has an important influence on the choice. Where a local spring is not available, the water must be piped from the reservoirs of the nearest town, and the number of hospitals that can be allowed to rely on the water supply of any one town is, of course, limited by the other demands on that source. The lighting of a hospital by electricity gives comparatively little trouble, for it is usually manufactured by plant in the hospital grounds, and it can be used for heating a bed or stretcher in the manner indicated above. Improvements of hospitals in matters of detail are continually being made, and some involve engineering assistance to a greater or less extent. A many-roomed solidly built operating unit is now, we believe, to be found at every hospital, even though the remainder of its accommodation be in tents.

We hear that in some instances it has been found desirable to remove medical units out of towns which have a special attraction for enemy bombing machines. This precaution, however, has not always been successful, and it would appear that some hospitals up-country have not found that their distance from a town or village, or from other camps, has lessened the frequency with which aeroplane attacks are threatened. It has been, in some instances, necessary to build large bomb-proof shelters for the protection of such patients as can be moved into them promptly.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died of Wounds.

CAPTAIN G. A. HARVEY, R.A.M.C.

Captain Gilbert Aberdeen Harvey, R.A.M.C., died of wounds in a casualty clearing station on November 25th. He was the eldest son of the late James Harvey, of Adelaide, South Australia, and was educated at Adelaide University, where he graduated M.B. and Ch.B. in 1911. After serving as house-surgeon and house-physician at the Adelaide Hospital, and at the Adelaide Children's Hospital, he came to England, and took the post of house-surgeon of the West London Hospital. He joined the Special Reserve of the R.A.M.C. as a lieutenant on October 19th, 1914, and was promoted to captain after a year's service.

Died on Service.

MAJOR R. H. BONNYCASTLE, C.A.M.C.

Major Richard Henry Bonnycastle died on October 7th from pneumonia after a few days' illness. He was born in Ontario in 1881, the son of one of the earlier settlers in that district, and received his medical education at the

University of Toronto, where he graduated in 1905, and in the following year commenced practice at Campbellford. He received a commission in the R.A.M.C. in May, 1915, and went to France in July, 1915, with the Scottish Division. Subsequently he transferred to the C.A.M.C. and served in the trenches for over a year. He was promoted to major in 1916 and returned to Canada a few months ago in charge of a party of wounded and was appointed superintendent of training and hospital work at Valcartier Camp, Quebec. He leaves a widow and two children.

Wounded.

Captain J. R. Barriskill, Australian A.M.C.
 Captain S. G. Gibson, Australian A.M.C.
 Captain N. McA. Gregg, R.A.M.C. (temporary).
 Captain S. H. Harris, R.A.M.C. (temporary).
 Captain C. Hunter, R.A.M.C. (temporary).
 Captain A. Jones, R.A.M.C. (temporary).
 Captain A. J. A. McCabe-Dallas, R.A.M.C. (temporary).
 Captain W. W. Morrison, R.A.M.C. (temporary).
 Captain K. M. Nelson, M.C., R.A.M.C. (temporary).
 Captain T. F. B. Reid, R.A.M.C. (temporary).
 Captain H. F. Woods, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Atkinson, Miles Linzee, Second Lieutenant Tank Corps, only surviving son of Dr. Miles C. Atkinson of Leamington, killed November 20th, aged 29. He was born in 1888 and educated at Fettes College, at Emmanuel College, Cambridge, and at St. Thomas's Hospital. At Fettes he was in the Rugby fifteen, cricket eleven, and gymnasium eight. He played full back for Cambridge and also represented St. Thomas's, the United Hospitals, and Surrey. Early in the war he enlisted in the Machine Gun Corps, served for over a year abroad, and was invalided home. On his recovery he was given a commission in the Tank Corps, and returned to France in June, 1917.

Atkinson, Victor Rupert, Second Lieutenant West Riding Regiment (Duke of Wellington's), only surviving son of Dr. Atkinson of Beverley. Settled, killed November 23rd, aged 20. He was educated at Giggleswick School, where he was in the O.T.C., got his commission from the Inns of Court O.T.C. last March, and went to the front on April 6th.

Bond, Alexander Beckett, Sergeant 16th Battalion Australian Imperial Force, son of Dr. J. W. Bond of London, died in the war prisoners' camp at Munster, Westphalia, on November 5th, aged 26.

Clouting, Frederick Herbert, Sergeant Australian Army Service Corps, youngest son of the late J. R. Clouting, F.R.C.S., of Sevenoaks, killed November 3rd, aged 34.

Ensor, John Collen, Lieutenant Welsh Regiment, younger son of the late Henry Collen Ensor, ophthalmic surgeon, Cardiff, died on November 26th of wounds received on November 24th. He was educated at Llandaff Cathedral School and at Epsom College, and gained a classical scholarship at Cardiff University College, where he was studying medicine. When the war began he was in the College R.A.M.C. unit, and was mobilized with it. He got his commission on January 7th, 1915, and had been at the front for two years.

Snell, E. A. G., Major Bedfordshire Regiment and King's African Rifles, only son of Dr. G. Snell, late Colonial Medical Service, killed November 16th. He got his first commission in the Bedfords on September 14th, 1914, and was seconded for service with the King's African Rifles two months later.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

MENTIONED IN DISPATCHES.

A DISPATCH dated October 25th, 1917, from Lieutenant-General G. F. Milne, Commander-in-Chief, British Salonica Force, bringing to notice a list of officers, warrant officers, non-commissioned officers, men, and nursing staff for gallant conduct and distinguished services during the previous six months, was published as a special Supplement to the *London Gazette* on November 28th.

The following medical officers are included in the list:

STAFF.

Colonels: M. P. C. Holt, K.C.M.G., C.B., D.S.O., A.M.S.; G. T. Rawnsley, C.M.G., A.M.S.

Lieut.-Colonel and Brevet Colonel (temporary Colonel) F. Smith, C.M.G., D.S.O., R.A.M.C.

Lieut.-Colonels (temporary Colonels): W. H. S. Nickerson, V.C., C.M.G., M.B., R.A.M.C.; F. S. Penny, C.M.G., M.B., R.A.M.C.

Lieut.-Colonel (acting Colonel) A. R. Aldridge, C.S.I., C.M.G., M.B., R.A.M.C. (Res. of Off.).

Lieut.-Colonels: E. T. F. Birrell, C.B., C.M.G., M.B., R.A.M.C.; H. J. M. Buist, D.S.O., M.B., R.A.M.C.; J. E. Hodgson, R.A.M.C.

Temporary Lieut.-Colonel E. H. Starling, M.D., F.R.C.P., F.R.S., R.A.M.C.

Majors: P. G. Easton, D.S.O., R.A.M.C., J. T. Johnson, D.S.O., M.D., R.A.M.C.
Captains: W. R. Galwey, M.C., R.A.M.C., N. V. Lothian, M.B., R.A.M.C., M. J. Williamson, M.C., M.B., R.A.M.C.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonels: F. Aslie, C. B. Martin, M.B., L. F. Smith, C.M.G., M.B., S. H. Withers, C.M.G., M.B.
Temporary Lieut.-Colonel L. S. Dudgeon, F.R.C.P.
Majors (temporary Lieut.-Colonels): J. Gray, A. E. Kidd, M.B.

Majors (acting Lieut.-Colonels): D. L. Fisher, M.B., J. Ward, Major E. B. Waggett, M.B.
Temporary Major J. W. Struthers, M.B., F.R.C.S.E.
Captains (temporary Colonels, A.M.S.): T. C. English, C.M.G., M.B., F.R.C.S., J. P. Stewart, C.B., M.D., F.R.C.P.
Captain and Brevet-Major (acting Lieut.-Colonel) B. Johnson, M.B.

Captain (acting Lieut.-Colonel) P. S. Tomlinson.
Captains (temporary Majors): G. H. Colt, M.B., F.R.C.S., A. W. Falconer, M.B., K. W. Monsarrat, M.B., F.R.C.S.

Captains: A. E. Barnes, M.B., G. B. Brand, M.B., R. D. Cameron, M.B., T. Carnwath, M.B. (S.R.), W. F. Christie, M.B., W. K. Churchouse, F. H. Coyne, M.B., B. L. Davis, I. D. Dickson, M.D., H. A. T. Fairbank, F.R.C.S., W. B. Foley, M.B., J. F. Gaskell, M.D., E. G. Ganett, M.B., F.R.C.S., A. D. Griffith, M.D., F.R.S., A. W. Harrington, M.D., N. H. Harrison, J. R. Hill, M.B., H. S. Hollis, M.B., B. Hughes, M.B., F.R.C.S. (West Yorks Regiment), R. E. Kelly, M.D., F.R.C.S., G. F. V. Leary, M.B., W. A. Lethem, M.B., N. L. Lochrane, M.B., A. C. Macdonald (S.R.), D. Mallam, W. J. F. Mayne, M.B., P. H. Mitchiner, M.B., F.R.C.S., O. J. O'B. O'Hanlon, M.B., F.R.C.S., A. Oliver, M.D., L. J. Sheil, M.D., R. M. Vick, E. A. Wilson, M.B.

Temporary Captain (acting Lieut.-Colonel): C. V. Bulstrode (Major R.H.A.).

Temporary Captains: D. I. Anderson, M.B., R. D. Attwood, J. Bain, M.B., A. Benjamin, M.B., W. H. Brodie, M.B., M. S. Bryce, M.C., M.B., G. B. Burwell, M.C., M.B., L. Cassidy, M.B., F.R.C.S.I., A. H. Coleman, M.B., P. C. Davie, M.B., J. N. Dobbie, M.B., H. H. L. Ellison, R. R. Elworthy, M.D., H. R. Evans, M.D., D. Fettes, M.B., W. H. Fleetwood, J. G. Forbes, M.D., A. R. Green, M.B., C. S. van R. Harwood, M.B., J. F. C. Haslam, M.B., J. F. Hoare, H. G. Hobson, J. M. Kelly, M.D., A. A. Lees, W. K. McIntyre, M.B., H. H. Moffatt, H. G. Murray, M.B., D. R. E. Roberts, M.B., J. D. Watson, M.B., T. B. Williams, M.B., D. E. S. Wishart, M.B.

Lieutenants (temporary Captains): D. W. Beamish, A. M. McCutcheon, M.B.

Lieutenant W. Donald, M.B.
Quartermaster and honorary Captain (temporary Lieut.-Colonel) J. Keogh.

Quartermasters and honorary Lieutenants: J. Banks, W. Clegg, J. W. Corking.

Temporary Quartermasters and honorary Lieutenants: H. J. Angell, J. Cotter, A. Jackson.

MEDICAL WOMEN (ATTACHED R.A.M.C.)

Misses Mary A. Blair, Barbara M. Cunningham, Elsie J. Dalryell, Elizabeth M. Edwards, Edith B. Hollway.

CANADIAN ARMY MEDICAL CORPS.

Lieut.-Colonel G. Gow.
Major J. G. W. Johnson.
Captain (acting Major) D. A. L. Graham.
Captains: W. A. Clarke, A. B. Schinbein.

The dispatch also mentions Subassistant Surgeon Singh Bachint and one ward orderly of the I.M.S., sixty-six warrant officers, non-commissioned officers and men of the R.A.M.C., two warrant officers of the C.A.M.C., seventy-six members of the nursing services, including sixteen of the Canadian Army Nursing Service and five representatives of the British Red Cross Society.

England and Wales.

THE NEW NATIONAL FUND FOR WALES.

THE new Welsh National Fund for the Welfare of the Sailors and Soldiers of Wales and their Dependents, to which we referred last week, was successfully launched at a representative conference held at Shrewsbury on November 28th, under the presidency of Mrs. Lloyd George. By Brigadier-General Sir Owen Thomas, the Hon. Violet Douglas-Pennant, Mr. Ellis J. Griffith, K.C., M.P., and other speakers it was made abundantly clear that the object of the new fund was not to relieve the State from any of its obligations, but to supplement State aid where necessary, and to provide medical and surgical advice as well as pecuniary assistance to those direct sufferers from the war who might technically or otherwise be outside the scope of Government relief. Mr. Ellis Griffith, M.P., formerly Under Secretary at the Home Office, in a characteristic speech, was insistent upon the full

discharge by the State of its just obligations to the country's soldiers and sailors. The State must fulfil its responsibilities to the letter; but after the State had done all that it was bound to do, there would remain an important sphere in which a great deal of relief and advisory work could be done. And this, he said, was not by way of charity. That word had been completely banished from the vocabulary of those interested in this organization, which it was intended should be controlled by some one with the power of an official and the sympathy of a human being. Memorials to the dead were sometimes spoken of; the best memorial to the dead was to succour the living. It was not by monuments of bricks and mortar that the valiant dead were honoured, but by a heartfelt resolve to place their wives and children permanently beyond the pale of want. Our fighting men stood before us as the sole saviours of our inheritance. They had not failed us in the hour of need; let us see to it that we did not fail them.

After some discussion as to the constitution of the administrative committee a resolution to pursue an active campaign in support of the object in view was unanimously adopted. It was resolved to ask the Prince of Wales to become patron. Mrs. Lloyd George was appointed president, Lord Plymouth and Sir O. Thomas vice-presidents, and Sir Owen Philipps, K.C.M.G., and Sir E. Vincent Evans, honorary treasurers, with Messrs. W. Lewis and Marlay Samson as honorary secretaries.

THE WELSH HOSPITAL FOR LIMBLESS SOLDIERS.

THE Prince of Wales's Hospital for Limbless Soldiers at Cardiff has been fortunate from the time it was initiated a couple of years ago by Colonel Lynn Thomas, C.B., C.M.G., in its number of benefactions, and it is gratifying to find that now it is in full working order benefactors are still coming forward to help and to encourage the movement. At a special reception held at the hospital on December 1st Miss Smith, a former lady mayoress of the city, presented to the institution a full-sized billiard table, a piano, a cinematograph lantern, a cabinet gramophone, twenty card tables, and a clock for the use and entertainment of the men undergoing treatment there. Her brother, Dr. R. J. Smith, during his mayoralty took an active interest in the establishment of the hospital, which was the gift of Cardiff to the Principality and its disabled heroes, and the presentation, purchased out of the surplus of the fund raised in June, 1916, at the Lady Mayoress's fête for providing a motor ambulance launch for service on the Tigris, was supported by the presence of the Lord and Lady Mayoress (Alderman and Mrs. Roberts), the town clerk Mr. J. L. Wheatley, and several of the aldermen and councillors of the city. The Lord Mayor, seconded by Lord Aberdare, and supported by Colonel Lynn Thomas, expressed the thanks of the hospital committee to Miss Smith, an expression of thanks which was more than cordially cheered by the sixty patients who are enjoying the benefits of the institution, and who took a lively interest in the proceedings.

THE CANCER HOSPITAL, MANCHESTER.

THE report presented to the annual meeting of the Christie Hospital (Cancer Pavilion), Manchester, on November 30th, when Sir Daniel McCabe was in the chair, stated that the work of the hospital had been continued under constant strain. The number of in-patients treated during the year was 109, and 16 had been admitted for radium treatment. Professor Wild, in replying to a vote of thanks to the medical and surgical staff, said that the radium treatment had been used extensively in all suitable cases, but it was still too soon to say definitely what could be accomplished by it. All that could be said was that it was distinctly promising. Sir William Milligan agreed that a great deal more knowledge and experience were needed before a final opinion could be given though he was still an optimist as to the value of radium. At the same time he thought they could not too much rub the idea into the minds of the public, as well as of the medical profession, that operative treatment in the early stages of cancer was the great salvation. Dr. Burrows said there was every hope that the exact doses of radium required in different types of cases would soon be ascertained. Owing to the war, research work had been greatly hindered, but it was hoped to start it again when the war ended, or even before, and to enlarge the institution.

Scotland.

WAR DRESSINGS SUPPLY.

In the official report of a committee of British surgeons who visited France last summer on the Carrel-Dakin treatment, published in the *BRITISH MEDICAL JOURNAL* of November 3rd, p. 597, reference was made to the advantage and economy effected by using sphagnum moss in carrying out the method. The director of the War Dressings Supply (sphagnum moss), Edinburgh, writes for the information of surgeons in naval and military hospitals to point out that this organization supplies not only surgical dressings made of sphagnum moss, but also moss pads specially prepared for Carrel-Dakin treatment. The latter are packed rather fuller than the ordinary dressings. The dressings are supplied as soft dressings, soft sublimate dressings or compressed sublimated cakes, all put up in muslin bags. The dressings can be obtained free on requisition to the D.G.V.O., Scotland House, New Scotland Yard, London, for naval and military patients. It is well to state whether the dressings are required for the Carrel-Dakin method. The trade is not supplied, nor civil practitioners, except when the dressings are for use in military hospitals.

THE LATE DR. ELSIE INGLIS.

In last week's *JOURNAL* there appeared a short obituary notice of Dr. Elsie Maud Inglis. We are indebted to Dr. Beatrice Russell for a personal memoir from which we take the following extracts, supplementing the details already given:

To the many friends of Dr. Elsie Inglis the news of her death came as a very unexpected blow. That her health was unsatisfactory was known from a telegram received from her a few days before she arrived in this country, but the outlook expressed was so definitely towards further work and new activities that her friends were hopeful that need for a period of rest was all that the message implied. On the arrival of her unit at Newcastle again a reassuring message reached her friends and family circle, and as it was evident that Dr. Inglis intended to proceed to London before going home to Scotland no special anxiety was felt. Shortly however, after landing at Newcastle on November 25th, serious symptoms supervened and her condition became critical. She was conscious until a few minutes before her death on the evening of November 26th, facing the end with calmness and serenity. Her friends then learnt that she had been struggling against ill health for months past, but had refused to come home until her work was finished.

Apart from the practice of her profession, Dr. Inglis was actively interested in public affairs. She took a deep interest in all questions connected with the medical education of women, and took a foremost part in every movement to obtain greater facilities for women medical students. She was keenly interested in political matters, more especially devoting herself to the cause of women's suffrage, and for some years acted as honorary secretary to the Scottish Federation of Women's Suffrage Societies. Dr. Inglis was an inspiring leader, for in addition to her strong and always lovable personality, she was possessed of an unbounded optimism, which never deserted her. She spoke easily and well, and never spared herself in any cause she had at heart. We are not yet at liberty to speak fully of the services which she rendered to the Serbian army, but all friends of Serbia know the value to that nation of Dr. Inglis's vigorous support and championship.

Mors janua vitae. She has passed on, and we look after her with love and pride. A devoted doctor, a warm-hearted woman, a very generous opponent, and the most loyal of friends.

Ireland.

POOR LAW MEDICAL OFFICERS' BONUSES.

At a recent meeting of the Listowel Guardians a letter was read from the Local Government Board relative to the proposal of the guardians to grant a bonus of £10 each to the medical officers of the union, and pointing out that the recent award of the Civil Service Conciliation and

Arbitration Board was limited to (1) whole-time employees at salaries of £250 a year or less, and (2) part-time employees engaged in manual duties. The award contained no provision applying to any class of official upon a footing similar to that of Irish Poor Law medical officers, and those officers might reasonably be expected to bear their personal shares of the burden due to and dependent on the existence of the abnormal conditions which now prevailed in consequence of the war. As an alternative to the guardians' proposal the board suggested that the medical officers who had not reached their maximum salaries under the scale would be allowed, say, £5 or £10 as an immediate increase of salary, with a further increment accrued under the scale on completion of the necessary qualifying periods. The Chairman of the Board of Guardians remarked that the letter was the most sensible he had ever seen from the Local Government Board. The Poor Law medical officers, however, do not endorse the chairman's view, particularly the smug statement in the letter that "Poor Law medical officers might reasonably be expected to bear their personal shares of the burden due to and dependent on the existence of the abnormal conditions which now prevailed in consequence of the war." Before the outbreak of the war the salaries of Poor Law medical officers were admitted to be less than the working expenses of their districts. Now that the cost of living and travelling has more than doubled the expenditure of Poor Law medical officers, the Local Government Board, in addition to its gratuitous advice, suggests that a board of guardians may give an increase of threepence a day to their medical officers! In these circumstances it is not to be wondered that the appeals of the Local Government Board to enlist the co-operation of its Poor Law medical officers to further its schemes for "public welfare" fall on ears that are not very receptive.

The difficulty is in an acute stage at Ballinrobe; at a special meeting of the guardians Sir J. A. MacCullagh, Senior Medical Inspector, Local Government Board, urged a friendly settlement, and the doctors, at the request of the County Association and the Local Government Board, withdrew their resignations; the guardians, however, refused to make any advance.

DOCTORS OF MILITARY AGE AND THE LOCAL GOVERNMENT BOARD.

In the King's Bench Division, Dublin, last week, judgement was given in favour of the Local Government Board in a case raised by the Lismore Guardians, which involved a question as to the power of the Local Government Board in the exercise of its discretion to decline to approve of the appointment of Dr. Cronin as medical dispensary officer on the ground that he was of military age, due regard being had by them to proper and satisfactory provision of medical relief for the sick poor. The Court held unanimously that the Local Government Board had that power, and that it had exercised its discretion and jurisdiction in the matter legally and properly in the existing circumstances. The Lord Chief Justice in a considered judgement said that the question for the decision of the Court in this particular case was narrowed down to this: was it open to the Local Government Board in the exercise of its discretion to require that in view of the national and military exigencies, the appointment of medical officers during the war should be confined to practitioners over military age, in cases in which other suitable and satisfactory arrangements could be made for the medical relief of the sick poor? He was satisfied, and so, he believed, were the other members of the Court, that so long as the Board had due regard to the paramount necessity of suitable provision for the medical relief of the sick poor it was open to that great department of the State to refuse, in these days of national and unprecedented strain, to encourage by premium or inducement medical practitioners of military age to seek civil appointments. He declined to entertain the suggestion (made by the applicants) that the Local Government Board in enforcing this policy was solely actuated by the indirect motive of enforcing the conscription of the medical profession in Ireland, being of opinion that it had no foundation upon any of the documents or facts in evidence. To attempt to enforce conscription was one thing, but to encourage the performance of a patriotic duty by withholding premiums or inducements to seek civil employment was another, and a wholly different matter. There was no evidence to

show that the Local Government Board had in any respect failed to have regard to the provision of suitable and satisfactory medical relief for the sick poor of Tallow district, or that there was anything savouring either of illegality or excess of jurisdiction in any of the other matters taken into consideration in this particular case. Accordingly the Court decided that the application had failed both upon the law and upon the merits. This judgement may have the effect of putting an end to the attempts that are being made by various boards of guardians to evade the order made by the Local Government Board early in the war that in all cases in which other arrangements were possible, no doctor of military age should be appointed either temporarily or permanently to do Poor Law medical work.

Correspondence.

TRANSFUSION OF WHOLE BLOOD.

SIR.—Since blood transfusion seems just now to be occupying attention, I venture to bring to the notice of those who are more immediately interested in it the account of a research which was conducted by me in 1879 at the request of the Obstetrical Society of London, "to determine with what fluids and by what methods the operation of blood transfusion may best be performed." The work was published in vol. xxi of the *Transactions* of the society, and the results obtained are not without significance at the present time; indeed, certain of your recent correspondents are advocating methods which are in some respects similar to those which proved in my hands to be the best, although I think that they fall a little short of it. The paper is not a long one, but is full of detail, and has rather surprised me, on looking it up after an interval of nearly forty years, by its singularly modern aspect.

The chief conclusion I arrived at was that immediate transfusion—towards the heart of the recipient—from artery to artery through a simple rubber tube and glass cannula, filled beforehand with sodium carbonate solution, is not only easy but by far the most effectual method of restoration after severe haemorrhage; and that two minutes' flow is usually more than enough to obtain the desired result. Naturally, in so short a time as this there can be no question of clotting, and the loss of blood which the donor suffers is negligible. Injection of sodium citrate produces a marked fall of blood pressure; its employment should therefore be avoided.—I am, etc.,

EDWARD A. SCHÄFER.

Department of Physiology, Edinburgh,
November 28th.

AN OLD HOSPITAL DIETARY.

SIR.—In these days when the attention of the profession and public is particularly called to questions of diet, the following observations may be of some slight interest:

In the late Dr. G. Munro Smith's *History of the Bristol Royal Infirmary*, recently published, he mentions on p. 31 certain dietarys in vogue there during the second quarter of the eighteenth century, and gives details of two which enable a rough estimate to be made of their nutritive values.

Common Diet.

The first of these was the "common diet," which on four days of the week consisted of beef, bread, milk pottage, and bread and broth.

The caloric value of this diet works out thus:

	Calories.
10 ounces beef	650
12 ounces bread	928
1 pint "milk pottage"	400
1 basin bread and broth	150
	2,128

On three days in the week 1 pint of "rice milk" was substituted for the meat and basin of bread and broth, and on alternate days there was either 1 pint of broth or 2 oz. of cheese. Allowing the "rice milk" to contain 4 oz. of rice and half a pint of milk, this diet would give:

	Calories.
1 pint "rice milk"	608
12 ounces bread	928
2 ounces cheese	222
1 pint "milk pottage"	400
	2,158

The protein content works out as follows:

10 ounces meat	1.5 oz.
12 ounces bread	0.96 "
1 pint "milk pottage"	0.6 "
	3.06 oz.

or,

1 pint rice milk	0.6 oz.
12 ounces bread	0.96 "
2 ounces cheese	0.5 "
1 pint "milk pottage"	0.6 "
	2.66 oz.

The caloric value of this diet, though not high, was quite suitable for sick persons in bed, and was further increased in practice by the fact that mutton was allowed in place of beef, and that there was a liberal allowance of "small beer"—namely, three pints in summer and a quart in winter. Supposing this to contain 2 per cent. alcohol—not a high estimate—a quart would yield at least 140 additional calories.

The protein content is certainly not high; what strikes me as remarkable is how closely the alternative diets correspond in nutritive value and how nearly they approach modern scientific standards.

Dry Diet.

The other diet was called the "dry diet." It is not stated for what purpose it was intended; very likely oedematous or corpulent patients were fed thus:

It consisted of 6 oz. of meat, or 8 oz. of boiled rice, with two meals of bread and cheese, and 1 pint of beer or cider. If we assume that the bread was 12 oz. and the cheese 4, we get:

	Calories.
6 ounces beef	390
12 ounces bread	928
4 ounces cheese	444
1 pint beer	70
	1,832

or,

8 ounces rice	816
12 ounces bread	928
4 ounces cheese	444
1 pint beer	70
	2,258

The protein content works out at:

6 ounces meat	0.9 oz.
12 ounces bread	0.96 "
4 ounces cheese	1.0 "
	2.86 oz.

or,

8 ounces rice	0.64 oz.
12 ounces bread	0.96 "
4 ounces cheese	1.0 "
	2.6 oz.

This diet has therefore a higher protein content than the "common diet," but the caloric value of the alternatives is less equal.

The values have been calculated from Dr. E. I. Sprigg's pamphlet on *Food and How to Save It*.—I am, etc.,

Clifton, Nov. 27th.

J. M. FORTESCUE-BRICKDALE.

HOW IS THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS TO BE MADE?

SIR.—In your issue of November 24th Dr. A. Garvie rightly expresses the views of the profession on the difficulties of an early diagnosis of cases of pulmonary tuberculosis. He asks for the practical experiences of fellow general practitioners in connexion with the earliest diagnosis of incipient cases. In an article published in 1914¹ by Dr. Wm. Murdie and myself we pointed out that one of the chief difficulties was to ensure that patients will consult a medical practitioner at an early stage of the disease. The onset of this trouble is so insidious that, unless there is an attack of haemoptysis or pleuritic pain, it may never occur to a patient that there is anything much wrong. Coughs and colds are so prevalent in this country, especially in the winter, that, as a rule, nothing very much is thought of catarrhal attacks, and it is only when a patient begins to feel weak, loses weight, and suffers from anorexia, or one of the complications of the disease appears, that a medical man is consulted. An

¹ *Medical Press and Circular*, June 24th, 1914.

effective plan to meet this difficulty might be to distribute at intervals a short circular to every household explaining in a judicious manner the mild onset of symptoms and the harmfulness of delay in having an infection of this kind attended to. This is already done by some municipal councils in connexion with cancer. With one-fourth of our population insured, and so entitled to free medical advice, any patients in this section could be assured as to whether or not they were suffering from consumption.

The earlier the stage the easier is it to miss a definite diagnosis. The most careful percussion and auscultation may reveal little or nothing. Diagnosis by means of the x rays, tuberculin tests, or serum reactions, cannot be generally applied. The simplest and one of the most valuable tests at our disposal is the careful use of an accurate clinical thermometer. It is advisable to leave the thermometer in longer than usual to ensure a correct reading. When from the history and symptoms a suspicion of incipient tuberculosis arises, if an elevation of temperature occurs at some time of the day of even a half to three-quarters of a degree above the normal for some days, we hold that such a case should have the most careful observation so as to endeavour to prevent it going on to be an "open" case of pulmonary tuberculosis.

Unfortunately, many patients at the present time do not present themselves for diagnosis or treatment until they are already expectorating sputum. In such instances it is strongly advisable to have the most thorough and repeated examinations of the secretions for the tubercle bacillus. We should not be content with one or two negative results; but in all clinically suspicious cases should persevere with the search, examining the sputa at different intervals, even six, eight, or nine times, until we are fairly certain of the presence or absence of the bacillus of tubercle. Again, a complete bacteriological and cytological examination of the sputum is of great value in distinguishing between a pneumonic or influenzal infection, simple bronchial catarrh, and a tuberculous infection of the respiratory tract. This should be made at the earliest opportunity at the nearest laboratory.—I am, etc.,

Ballachulish, Nov. 26th.

LACHLAN GRANT.

THE WASSERMANN REACTION.

SIR.—In a report in the *BRITISH MEDICAL JOURNAL* of November 24th, p. 698, on the above reaction it is stated:

In the later stages, with certain exceptions, a rather higher proportion of undoubted syphilitic cases give negative results. . . .

I am writing to confirm this statement in the light of practical experience. Some time ago the blood of every newly admitted case was examined by the Wassermann method, and the results showed that in one case which was reported as "positive"—the patient had no signs or history of syphilis—he made a good mental recovery, and for more than three years has been in the army. In three other cases which gave a negative reaction the patients in each case suffered from general paralysis of the insane (which is syphilitic in origin), and the diagnosis was confirmed later by *post-mortem* examination.

In its infancy the Wassermann reaction was heralded as a great aid to mental specialists in the diagnosis of obscure cases of general paralysis, but in my opinion it is not always reliable.—I am, etc.,

GUY R. EAST, M.D., D.P.H., B.Hy.

Northumberland County Asylum, Morpeth,
Nov. 24th.

REMUNERATION OF RURAL PRACTITIONERS.

SIR.—I happen to be located in a hilly part of Devon with a very scattered practice; in several directions there are villages, hamlets, or groups of cottages within a radius of three or four miles, but the gradients are such that it not infrequently takes the greater part, if not the whole, of a gallon of petrol to pay a single visit (unfortunately they are often single in the sense of being the only one in that particular direction), the greater part of the journey having to be done on "first" speed.

It does not appear to me to be exorbitant if one asks that at least the petrol may be paid for even if such insignificant items as time, tyres, and professional services rendered are not to be taken into account. Drugs, too, is another sore point with those of us who have to dispense

our own—still only 2s. a head, as in pre-war times, although the prices in some cases are five or six times and sometimes ten times as much.—I am, etc.,

November 27th.

STILL ANOTHER RURAL G.P.

THE THEORY OF IMMUNITY.

SIR.—As one interested in all coming finally under the head of biology I wish to ask whether it is not time to simplify the theory of immunity. Much modern work seems intended to support "orthodox Ehrlichism," though by the multiplication of sub-hypotheses its confusion grows worse confounded. Moreover, the giant molecule and side-chain theory is wholly discredited by such physiologists as Bayliss, Hopkins, and others. The "biogen" can no longer be considered a chemical entity, but must be regarded as a complex system of molecules whose interaction, not their substance, is life, while before long the cell will be looked on as a highly organized symbiotic community of labile molecules. Nevertheless the structure built on the foundation of the giant molecule still grows. I find that many workers have never seen, much less considered, Moore and Whitley's paper on Enzymes and immune bodies.¹ This note puts forward the view that immune bodies should be classed with enzymes, the substrate being the cell or bacterium to be dissolved or the toxin to be rendered inert, and the "complement" the combining bodies with which either becomes chemically united. Such reactions are obviously similar to those which occur, in enzyme action, with the substrates and combining bodies of foods. May it not be, however, that nutrition reactions are in their origin essentially immunizing and that nutrition enzymes should therefore be regarded as a subclass of immune bodies, as these are a subclass of catalysts generally? The main difference between them is that the catalysts which deal with foods (in themselves "poisonous" before being broken down) are the result of long evolution, while the class commonly called immune bodies are either catalysts "provoked" *ad hoc* as a natural reaction of protoplasm or normal catalysts not specialized to deal with one substrate only.

Such a view gives the coherent picture wanted in explanation. It does away with the need of special names for fresh phenomena, and permits them to be described in the known language of colloidal chemistry. It seems legitimate to regard unaltered foods as poisonous bodies requiring to be dealt with before they can be used. If enzymes fail, foods remain a poison. They only become "foods" by exciting reactions which break them up. It is known that enzymes proper do not exist till they are provoked. We may compare the absence of lactase in the meat-fed dog until it has been fed on milk.

To some it will seem an inversion to reckon these enzymes a subclass under immune catalytic bodies. But if immunization is the result of the total defensive machinery which makes growth possible for protoplasm, nutrition enzymes may properly be regarded as the specialized catalytic immune bodies used in normal physiological upkeep. The view that they are to be classed as immune bodies is supported by Weinland and Abderhalden's work. Weinland showed that the subcutaneous injection of cane sugar provoked invertin, for carbohydrate in the blood stream is a foreign body. The tissues can produce new catalysts to deal with emergencies. The "Abderhalden test" shows that the intrusion of any foreign substance is followed by an antibody, which deals with it. Intrusive cells of the chorionic villi are thus disposed of. We do not know how "antibodies" are produced. They are possibly a result of the hostility by which each individual colony of cells in a symbiotic community inhibits its neighbours and preserves its own characteristics. Such processes are complex, but are not rendered less so by giving a special chemical name to every phenomenon observed. Agglutinins, precipitins, bacteriolysins, etc., are not entities; they only mean that certain obscure reactions occur.

Abderhalden applies his methods to the diagnosis of pregnancy.² The embryo produces "poisons" which affect the parent and are slowly overcome by a process of immunization. It thus seems that immunization should not be considered a special phenomenon, but the universal method of protective reaction against such different alien

¹ *Biochemical Journal*, 4, 136-168.

² *BRITISH MEDICAL JOURNAL*, March 29th, 1913, p. 677.

substrates as a carbohydrate and the toxins of pregnancy. The glands which produce zymogens for dealing with food when these "gens" are activated by the substrate, are obviously the evolutionary result of a long-continued action which in its early form is to be elicited from other tissues than these glands.

In nutrition we know what the combining bodies are. They are in fact complement. What, then, are the complements of immunity in infection? It may be inferred from the rapid loss of fat in most infections that they are lipid. In typhoid, where emaciation is not usually rapid, the special combining body may, perhaps, be found in parts of the small intestine. This might explain the ulceration of Peyer's patches. In extreme weakness with a febrile reaction it may be that the infection is proteolytic. It seems probable that what can be easiest spared goes first. Probably the function of the phagocytes is not their ingestive power but their capacity of being used as complement. Their ingestion of infective organisms may be only a failure of their resistance against the bacteria which combine with complement under the influence of the catalyst they have provoked. It is, in fact, the immune body which renders them liable to destruction. If sufficient lipid-complement, say, can be spared by the cell membranes the phagocytes survive. If the membrane fails they are attacked internally and perhaps die. If this is so the phagocytes play another rôle than that usually assigned to them. We get rid of metaphors in dealing with them, and come back to simple tropisms. The phagocytes are an easy source of complement. We may infer that the substrate bacterium "seeks" or combines with part of their substance rather than that they "seek" the substrate under the influence of the provoked catalyst. If this is so opsonins do not exist. The word merely means that under the influence of the immunizing catalyst the bacterium on contact combines with the phagocytic complement, not that the phagocyte becomes bacteriotropic. The collection of phagocytes in any given area of inflammation is due, not to their "purposeful" sacrifice, which seems too often implied, or to their being attracted to the spot, but to their incapacity to escape, after having been brought there by the blood or lymph stream or by the failure of the cells of the vascular walls to prevent their wandering.

I think these views tend to the simplification of theory. It may be stated tentatively that (1) to understand immunity it must be held to include the preparatory processes of nutrition; (2) nutrition enzymes are immune bodies or catalysts, perfected by ages of evolution, which have rendered the organism immune to certain compounds and have made "foods" of them; (3) What are generally called immune bodies are catalysts "provoked" *ad hoc* for dealing with the substrate infective bacterium or are unspecialized normal catalysts.

The terms employed in general physiology should thus be sufficient for bacteriology, and observers of fresh phenomena ought to be chary of coining new words. Their hasty multiplication usually implies some additional hypothesis. It is characteristic of a false explanation to require an increasing number of sub-hypotheses while a real one abolishes a multitude of superfluous terms and, displaying a phenomenon as the function of known variables, by such a disclosure is essentially a simplification.—I am, etc.,

London.

MORLEY ROBERTS.

LAY RADIOGRAPHERS AND ELECTRO- THERAPEUTICS.

SIR.—In your issue of November 24th "J. H. E." raises a question of great importance, both to the medical profession and to the public, when he calls attention to the vast number of lay persons engaged in the practice of radiography and electro-therapeutics and asks for steps to be taken to put a stop to the practice.

The state of affairs he describes not only existed in civil hospitals in small towns and in the country before the war, but is actually true of large general hospitals in London at the present time. There is a general hospital in London where a layman has been appointed to the position of radiographer and has done the work for the past two or three years and is still doing it. There is also a large general teaching hospital in the heart of London where a layman has just recently been appointed in charge of

the x-ray and radiotherapeutic department, and this same layman is engaged in private practice as a radiographer in the West End.

There was one of the largest general hospitals in London where until quite recently, if not still, the out-patient x-ray department was run entirely by a layman who was known to the patients as Dr. —, and the lay-worker at another large general hospital, also in London, was actively engaged in private x-ray work in the locality of his residence.

It is quite time, when we consider the important—nay, indispensable—part the x-ray plays in both medical and surgical practice both as a diagnostic and curative agent, that its use should be entrusted to none but specially trained registered medical practitioners. Furthermore, it seems to belittle the medical and surgical staffs of large hospitals when their members depend upon the laity for diagnosis.—I am, etc.,

London, W., Nov. 26th.

CHRISTOPHER KEMPSTER.

EPSOM COLLEGE.

SIR.—I would again ask you to allow me to make an earnest appeal to your readers for contributions to the Royal Medical Foundation of Epsom College.

This Foundation provides an education of the highest class, together with maintenance, clothing, and pocket-money for fifty necessitous sons of medical men, and gives pensions of £30 each to fifty aged members, or widows of members of the medical profession in reduced circumstances. In order to maintain the full numbers of beneficiaries a sum of about £4,500 must be obtained by annual contributions.

I appeal to all medical men as well as to members of their families who do not already contribute regularly, to assist the Council at this particularly difficult time by becoming annual subscribers. In the case of those who do subscribe I earnestly request them to increase if possible their regular contribution during the period of the war, and subsequently for two or three years at least.

An increased number of applications is sure to be received as a consequence of the war. Already the Governors have elected as a Foundation Scholar the son of a medical officer who was killed in action on board H.M.S. *Good Hope*, and there are at this time on the list of candidates the son of a medical man who was lost in the *Royal Edward* when she was torpedoed in August, 1916, and the son of another medical officer who was killed whilst in command of a battery in France last April.—I am, etc.,

HENRY MORRIS,

Honorary Treasurer of Epsom College and its
Royal Medical Foundation.

8, Cavendish Square, London, W.,
Nov. 27th.

CHRISTMAS APPEAL OF THE Y.M.C.A.

SIR.—The members of our profession in all parts of the empire have given so generously of their skill, time, money, health, and life for the wounded and sick of our navy and army that it would seem almost an insult to ask further of them.

The appeal, however, which is appearing in the leading London and provincial newspapers is a national one, and we would not wish to be left out of it, and, moreover, this appeal is for the many who are fighting or preparing to fight for us, and not only for those who are *hors de combat*.

Our men are worth anything we can give them, and this appeal for £500,000 for the work of the Y.M.C.A. among them is practically equivalent to handing each man three shillings as a Christmas box.

Major W. McAdam Eccles is willing to receive with thanks whatever sum members of the profession will send to his address as given below before December 20th, 1917, and to hand it over as the contribution of our profession to this fund.—We are, etc.,

ALFRED PEARCE GOULD, K.C.V.O.

DONALD MACALISTER, K.C.B.

Dec. 1st.

Obituary.

PETER MACGREGOR, F.R.C.S. EDIN., J.P.,
HUDDERSFIELD.

MR. PETER MACGREGOR, who occupied a prominent position in Huddersfield for nearly forty years, died at his country cottage at Oswaldkirk Yorkshire, on November 15th, in his sixty third year, after a long and trying illness. He received his medical training at Edinburgh, and qualified L.R.C.P. and L.R.C.S. Edin. in 1877. Some years afterwards he took the Fellowship. After qualifying he went on a whaling expedition, and, later, acted as assistant for a short time in Lancashire. Then he settled down in Lockwood, Huddersfield, soon made his presence felt, and quickly acquired an extensive practice. He was capable of a great amount of work, and never spared himself. Few men in the medical profession can ever have worked harder than he did for many years. He did not, however, confine himself exclusively to his profession. Before long he became known as an eloquent speaker, and, as he was a man of wide and varied information, with a keen, incisive intellect, his speeches were always listened to with great interest. He became a prominent member of the Huddersfield Corporation, but municipal work, with its numerous committee meetings, did not appeal to him, and, after a few years, he retired from it.

About twenty years ago Mr. MacGregor was appointed honorary surgeon to the Huddersfield Infirmary. He was a daring operator, and took keen interest in his surgical work. His favourite operation was thyroidectomy, and in its performance he was very successful. When the Huddersfield War Hospital, with 500 beds, was opened in 1915, he received a commission with the rank of major, and threw himself with enthusiasm into the work. He had at that time already more than enough work to do as surgeon to the Royal Infirmary and in his private practice. Two days before he was taken seriously ill he went through a long list of operations at the infirmary though feeling far from well. He had been a man of much vigour and abounding energy both physically and mentally, but the severe strain was telling upon him, and when pneumonia set in his resistance was low. He did, however, make a partial recovery, but was never well enough to return to work. His great ambition was to get back to the war hospital.

"Peter" or "Mac," as he was affectionately called, was one of the best known and most popular men in the Huddersfield district. He was a master of repartee; many of his witty sayings will be long remembered. For many years he was much in evidence on the political platform, his sympathies being strongly on the Conservative side. His generosity knew no bounds, and he was particularly fond of children, seldom passing a poor boy or girl without the bestowal of some gift. He loved his profession, but disliked the business side of it. At the time of his death he was President of the West Riding Medical Charitable Society, which has done so much for the less fortunate members of the profession, in the area it covers, during the last three-quarters of a century.

At the funeral on November 20th the route was lined on either side for a distance of two miles with people closely packed in many places. The mills were closed, and it was touching to see the manifestation of sympathy amongst the workpeople for whom Mr. MacGregor had done so much.

EDWARD PARKER YOUNG, M.R.C.S. L.S.A.

MR. EDWARD PARKER YOUNG, who died recently at Westbourne Square, Hyde Park, aged 79, was well known for over fifty years as a practitioner in Paddington. After studying medicine at St. Mary's Hospital he took the diplomas of M.R.C.S. and L.S.A. in 1860. He was a member of the first London County Council, a past master of the Society of Apothecaries, and an original member of the Central Midwives Board. He was also a governor of St. Mary's and the Lock Hospitals, a former chairman of the Royal Medical Benevolent Fund, and a prominent member of various religious societies, including the Y.M.C.A., of whose national council he was vice-president.

We have received the following appreciation from Sir Francis Champneys:

I have been intimately associated with Mr. Parker Young since 1902, when the newly constituted Central Midwives Board began to hold its preliminary meetings, until a few months ago, when he retired on account of failing health. He was a man of marked personality, of independent views, courageous in maintaining them, even when he was in a minority of one, precise in business, and a systematic critic of the least inaccuracy. His honesty was so apparent that no divergence of views ever interfered with the friendliest personal relations, especially as such divergence almost always concerned methods rather than principles. Personally he was a man of strong and deep religious convictions, which bore fruit in work for the benefit of his fellow creatures in many charitable and philanthropic enterprises. He spent much time in attending boards and committees of such institutions, and put his heart into all which he undertook. He bore his illness, which was long and painful, with great courage and patience, and maintained his interest in his work long after he ceased to be able to take part in it. He will be greatly missed, and will be remembered as a very public spirited, charitable, and self-sacrificing man, and as a type of what a high-minded general practitioner of the old school could be.

Medical News.

COLONEL SIR THOMAS OLIVER, M.D., has been appointed a deputy lieutenant for the county of Northumberland.

DR. ARTHUR KEITH, F.R.S., Conservator of the Museum of the Royal College of Surgeons, has been appointed Fullerian Professor of Physiology in the Royal Institution.

DR. M. J. NOLAN, R.M.S., Down District Asylum, has been appointed Consulting Visitor in Lunacy in the place of the late Lieut.-Colonel Graham, M.D.

SIR ROBERT ARMSTRONG-JONES will open a discussion on alcohol and mental states at the meeting of the Society for the Study of Inebriety on January 8th, 1918, at 4 p.m.

Surgeon Lieut.-Colonel Sir Warren Crooke Lawless, C.I.E., and Lieut.-Colonel Thomas H. Symons have been appointed Commander and Officer respectively of the Most Excellent Order of the British Empire.

A NEW fasciculus of the *Athenaeum Subject Index to Periodicals* (November, 1917, 5s. net) contains references to publications on historical, political, and economic sciences in 1916. Appended to the subject index is an index of authors.

IN a Chadwick Trust lecture delivered on December 1st at Leicester by Professor H. T. Davidge, on electricity and the hygiene of the body, a warning was given that quite ignorant and unskilled persons might under present conditions exploit that large section of the public to whom the mysterious words "electricity" and "radium" might mean anything.

THE medical profession will be represented next year in the North Wales shrievalty. Dr. R. D. Evans of Blaenau-Festiniog has been appointed high sheriff for the county of Merioneth. Dr. Evans is the father of Dr. Carey Evans, who won distinction in the Mesopotamia campaign and was recently married to Miss Olwen Lloyd George, the eldest daughter of the Prime Minister.

THE University of London Press is issuing this week the first batch of volumes of translations of books published in the Collection *Horizon* by Masson, many of which have been reviewed in our columns. The series of translations is being reproduced under the general editorship of Sir Alfred Keogh, and the English translation has in each case been edited by a specialist. The first batch includes volumes on the psychoneuroses of war (6s.); hysteria (6s.); the after-effects of wounds (6s.); typhoid and paratyphoid fevers (6s.); the dysenteries, cholera, and exanthematic typhus (6s.); syphilis and the army (6s.); and the treatment of infected wounds (5s.).

THE autumn meeting of the Irish Medical Schools' and Graduates' Association was held on November 28th at Pagani's Restaurant, Surgeon-General Sir Laurence Gubbins, K.C.B., President, in the chair. It was resolved to send a donation of five guineas to the Royal Medical Benevolent Fund Society of Ireland. At the dinner which took place subsequently covers were laid for seventy-four members and guests. The toast of "Our defenders" was acknowledged by Major T. J. Crean, V.C., D.S.O., and Colonel O'Sullivan. The toast of "Our guests" was

proposed by Dr. J. A. Macdonald, who said the association was fortunate in having at its board that night Captain Archer Redmond, the gallant son of the leader of one of the parties in the House of Commons, as well as the leader himself of another party. Mr. Stephen Walsh, M.P., in responding, said he looked forward hopefully to a day when all Irishmen would follow the example set by that association, the members of which included men and women of all creeds and political parties, and yet during the forty years of its existence there had not been even the whisper of a quarrel. This showed that men educated in Ireland for the medical profession rose above the bitterness and pettiness of political and sectarian strife, and worked in perfect harmony for the advancement of science and the good of the community. Dr. T. Jenner Verrall proposed "Continued prosperity to the association," and coupled with the toast the name of Sir Laurence Gubbins, who, in responding, said he felt much honoured by being invited to occupy a chair which had been filled by men of such distinction as Lord Ilkerton, Sir William MacCormac, Professor Alexander Macalister, and their old and valued friend Dr. Macnaughton Jones, from whose sick bed there had come that evening an affectionate message.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them, with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and Journal are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, Aitiology, Westrand, London; telephone, 2634, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate, Westrand, London; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, Medisecra, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC.

AMENORRHOEA IN WAR TIME.

DR. JAMES OLIVER, F.R.S. Edin. (London, W.), writes: In your issue of to-day (December 1st) under the above heading, you draw attention to the fact that in Germany there has, in consequence apparently of war conditions, been noted a "great increase of amenorrhoea in women of child bearing age." In this country, prior to the war, I had already observed that intermittent menstruation, as I was disposed to call the condition—that is, the suspension of menstruation now and then for intervals varying from five or six weeks to many months—was becoming more and more common. Since war broke out the derangement has probably increased somewhat. Nature has predicted that the menstrual discharge should recur somewhat regularly, about every four weeks, from about the age of 14 until about the age of 45, and that it should only be suspended during those thirty odd years because of the occurrence of pregnancy, and in some cases as a result of lactation too. This being so, it is quite clear that intermittent menstruation, whether it is or is not associated with any other untoward symptoms, is undoubtedly an indication of some derangement which calls for rectification. In this and other civilized countries there has also during the last decade been noted a growing inability to suckle, and one cannot help concluding that the cause of the disability to menstruate is not far removed from the cause of the disability to suckle. From a national point of view they are both physiological disabilities of some importance.

PALMYRA FIBRE AS A SUTURING MATERIAL IN PLACE OF SILKWORM GUT.

LIEUTENANT G. SRINIVASAMURTI, M.B., C.M., I.M.S., writes: At the instance of Dr. T. M. K. Nedungadi, District Surgeon, Cuddalore, S. India, I am communicating to you our experience in the use of palmyra fibre as a suturing material in place of silkworm gut. Silkworm gut was one of the articles of our annual indent which the Government medical stores at Madras had not in stock for supply this year, adding that there was not any prospect of any fresh supply in the near future. Being thus thrown on our own resources, we decided to give palmyra fibre a trial, and the experiment was an unqualified success.

The fibre is obtained from the fibrous netting that surrounds the bases of the leaves of the toddy palmyras growing

luxuriantly on the West Coast of India, especially Malabar; hence the fibre is also known as "Malabar fibre." It can be had in all required sizes; requires very little preparation before it is ready for use and is easily preserved; it keeps well and is easily sterilized; it is fairly strong and sufficiently flexible; is very cheap and is an entirely "Swadeshi" product, so that the supply is not likely to be overprecarious. In this connexion we may cite the following opinion of Dr. Newman, who, in speaking of silkworm gut in his *Aseptic Surgery*, says: "In spite of its hard and apparently unabsorbent texture, it is by no means so safe as it may look at first light." We therefore strongly recommend the use of palmyra fibre in all cases where silkworm gut is being hitherto used.

Supplies may be obtained from Messrs. T. S. Dutt and Co., chemists, Calicut, Madras Presidency, S. India.

BACTEROL IN RINGWORM.

DR. ROBERT HOWIE (Eastbourne) writes: On September 1st, 1917, I found my youngest son, aged 3½ years, had contracted ringworm of the head, and verified the diagnosis with the microscope. The first patch was very small, but the disease spread rapidly, until there were five patches on the head, and one on the forehead, one on the left eyebrow, and one on the left ear. I started at once having the patches damped with a watery solution of bacterol (1 in 500) every twenty minutes during the daytime for three days. This caused a little irritation of the scalp, so I lengthened the time to once every two hours, and this was continued for four weeks, when I believed the growth was all killed. The head was then washed every night with soap and a warm solution of bacterol (1 in 5,000) for two more weeks. I then examined several hairs under the microscope and found them healthy. A week later I asked a colleague to examine the boy's head, and take hairs from it for examination. He thought the head looked very well, and informed me the following day that neither he nor his partner could find any disease in any of the hairs which he had taken from different areas of the head. I have treated several cases of ringworm lately quite successfully with bacterol, and intend to treat all my ringworm cases in a similar manner. The treatment is so simple. No shaving or hair cutting is required, only damping the head with the lotion at frequent intervals. In some cases I have applied an ointment containing 1 per cent. bacterol when the child has scratched the head and caused small abrasions. Bacterol is an Italian preparation containing eucalyptus, iodine, formalin, and Alpine peppermint.

TYPHOID FEVER FOLLOWING A BITE BY A HORSE?

DR. T. G. MATHEWS (Kirkby Lonsdale) writes: It is so generally accepted that the only method of transmission of typhoid fever is through the alimentary canal that the following case, which suggests another and more direct entrance into the blood, seems to me to be worthy of record.

P. M., aged 41, came to my surgery on October 6th, 1917, suffering from a lacerated wound of the terminal phalanx of the left thumb the result of a bite from a horse.

He attended each succeeding day to have the wound dressed. This seemed at first to be healing up, but after a few days he complained of some stiffness in the shoulder on that side; the axillary glands were slightly enlarged.

On October 15th he asked me to go and see him as he felt too ill to walk. I found him in bed with a raised temperature, and complaining of malaise and severe headache. From that date until his death on November 3rd he remained in bed, the headache being at first intense, and being only relieved by morphine given hypodermically. On October 19th he had a few typical spots on the abdomen, and on successive days these increased until he had a very copious rash. All the symptoms of a severe attack of typhoid fever developed, and the temperature remained high.

A specimen of his blood was sent to Professor Delépine of Manchester on October 23rd, and was reported to be positive for typhoid.

On November 1st there was evidence of pneumonia in the left lung, and he sank rapidly, and died on the morning of November 3rd, exactly four weeks from the date on which (as I think) he was infected by the bite on his thumb.

I am of course aware that this may have been in the nature of a pure coincidence, but the date and method of the onset are strongly suggestive of the bacilli having gained a direct entrance to the blood or lymph stream.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	f	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 ..
A page	10 0 ..

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

Remarks

ON

PENETRATING GUNSHOT WOUNDS OF THE CHEST, AND THEIR TREATMENT.

BY

G. E. GASK, D.S.O., F.R.C.S., MAJOR R.A.M.C.(T.),

AND

K. D. WILKINSON, M.D., M.R.C.P.,

CAPTAIN R.A.M.C.(T.).

This paper is based on 500 cases which have come under our care during three periods, namely:

October 13th to December 12th, 1916	...	56 cases.
April 1st to April 25th, 1917	...	79 "
June 7th to August 31st, 1917	...	365 "

These periods cover different phases of warfare and include periods of heavy fighting and of relative quiet.

We have included all cases of penetrating wounds of the chest admitted to the casualty clearing station, however serious the complications, and have excluded those cases of concussion haemothorax in which the pleura had not been opened by the missile.

For the analysis of cases and results, shown in the subsequent tables, we have excluded the first two periods because:

1. It is uncertain that all chest wounds admitted to the casualty clearing stations were seen by us in those periods.

2. It is probable that the more serious cases were diverted by the field ambulances ahead of us to advanced operating centres.

3. The clearing stations at which we were working were so placed that a period of twenty-four hours elapsed between wounding and admission of patients. Thus many of the more seriously wounded must have died in advanced posts.

4. In this last period we have been able to follow up our cases to the base or England, and have thus been enabled to include base mortality with casualty clearing station mortality in the subsequent tables.

We think that the analysis of cases from one casualty clearing station will give a fairer conception of the mortality.

The objects of our investigation have been to determine accurately the cause of death, and the possibility of lessening mortality and shortening convalescence by early operation.

We wish to render our thanks to Surgeon-General O'Keefe, Surgeon-General Bruce Skinner, and Surgeon-General Porter, for facilities given for this investigation, and to Lieut.-Colonel J. E. Davey, O.C. Canadian Casualty Clearing Stations, and his staff, who have rendered us every possible assistance; also to the Medical Research Committee, which has furnished us with books and instruments.

CAUSES OF DEATH AND PROLONGED ILLNESS.

I. If the complicating wounds are disregarded the causes of death in pure chest wounds may be divided into three groups:

(a) Deaths a few hours after admission to a casualty clearing station, due to very extensive and severe injuries which can seldom be aided surgically.

(b) Deaths in a casualty clearing station after a few days. These are almost always due to sepsis of the pleural cavity and its contents.

(c) Deaths at the base; sepsis again is the great factor.

Similarly, prolonged illness is almost entirely due to sepsis.

Therefore treatment should be directed towards the elimination of infection in chest wounds as in any other wound.

II. The pleural cavity may become infected:

(a) By the missile and portions of cloth carried in by it. Splinters of indriven bone are a material factor both in causing and maintaining sepsis.

(b) Through the wound of the chest wall; a wound that opens directly into the pleural cavity, and through

which air is sucked, will always lead to infection. Further, a wound even of moderate dimensions, through which air is not being aspirated, unless adequately dealt with may become septic in the course of one or two days, and unless the thoracic cavity is sealed off organisms pass through into the pleural cavity, where they find the blood a convenient medium. This accounts for many cases which show septic changes only after four or five days.

(c) From the wound of the lung in which foreign body, bone, or clothing may be retained.

PRINCIPLES OF TREATMENT.

A patient admitted with a suspected penetrating wound of the chest is put to bed and allowed to rest undisturbed for one or two hours to recover from shock. The only exception to this rule is when there is a large opening into the pleura through which air is sucked. In such cases the opening is immediately closed by temporary skin suture without anaesthetic. This gives the patient immediate relief. We are strongly of opinion that all such wounds might be sewn up with great advantage at advanced dressing stations. The procedure is easy, rapid, and much more efficient than plugging and strapping.

The Italian surgeon Bastianelli recommends the use of a dumbbell-shaped pneumatic bag, which when inserted into an open thorax and inflated prevents suction of air, and also controls intercostal bleeding. We have no experience of its use, but the idea seems excellent.

A survey is then made of the whole patient, and all wounds examined; evidence of haemothorax, pneumothorax, or collapse of lung is sought. Much may be gained by careful examination of the movements of the chest as a whole; the position of the heart is of the greatest importance. The whole body should be searched for complicating wounds, especially with regard to abdominal and spinal injury. Cases in which the missile has not passed out of the body should be examined by x rays, by which valuable information may be gained concerning:

1. The position and size of the foreign body.
2. The existence and extent of haemothorax and pneumothorax.
3. The condition of the opposite lung, cardiac displacement, and movements of the diaphragm.

INDICATIONS FOR EARLY OPERATION.

The indications for early operation are:

1. A ragged wound of the soft parts.
2. Compound fracture of ribs.
3. Bleeding from parietal wound.
4. Suction of air into the pleural cavity.
5. Retention of a large foreign body in an accessible position.
6. Pain (often the result of indriven splinters of rib scratching the lung with every respiratory movement).
7. Rapidly increasing pneumothorax due to a valve-like opening into the pleural cavity, which allows air to be sucked in and prevents its expulsion.

TREATMENT WITHOUT OPERATION.

Where none of these indications is present—that is, when the wounds of the chest wall are small and clean, when there is no evidence of fractured ribs, when the foreign body retained in the lung or mediastinum is small—the case is treated on general medical principles. The patient is kept in bed, propped up or flat as he prefers, and a careful record is kept of the pulse, respiration, and temperature.

Haemothorax.

When the haemothorax is large enough to produce symptoms by its size it is aspirated; otherwise the chest is only needled if the condition of the patient suggests that a haemothorax is becoming infected, when a sample of blood is removed for bacteriological examination. The chief clinical signs of infection are a rising pulse rate, high temperature, sudden increase in the size of an effusion, or sudden occurrence of pneumothorax several days after the receipt of the wound.

Massive Collapse of Lung.

Apart from collapse of the injured lung as the direct result of an effusion of blood or air, we have noted massive

collapse in about 10 per cent. of cases (contralateral in 1 per cent.). It was invariably in the lower lobes, and is indicated by respiratory restriction of the chest wall with cyanosis and distress, diminution of percussion note, and bronchial breath sounds over the base of the lung. Theories as to the causation of this condition are numerous and unsatisfactory.

Cyanosis.

Cyanosis, which is often due to collapse of one or both lungs, is best treated by inhalation of oxygen for five or ten minutes every half-hour.

Pneumothorax.

Pneumothorax is frequently associated with haemothorax in the early stages, but, as a rule, the absorption of air is rapid, and when the chest is closed a pneumothorax may disappear completely within twelve hours after the receipt of the wound.

Occasionally the wound of the chest is of such a nature that some air may be sucked in by each inspiration, and yet none escape on expiration (valve-pneumothorax). The pneumothorax increases in size, and the distress of the patient is very marked. Aspiration is useless, and early operation, affording relief of pressure, followed by repair and closure of the chest wall, is the correct procedure.

Surgical Emphysema.

This is of frequent occurrence. Often it extends throughout the subcutaneous tissues, but does not require any special treatment even when very extensive.

Substernal Emphysema.—In addition to this general distribution it occurs in the extrapericardial fat and loose connective tissue of the anterior mediastinum. This "substernal emphysema" may give rise to physical signs, which are especially noticeable when the emphysema is localized to the mediastinal tissues. Such signs are:

1. Absence of the precordial area of dullness on percussion.
2. Crepitations which occur with each heart beat, and may more or less replace the heart sounds.
3. A pericardial, or pleuropericardial, murmur may be present, and may render a differential diagnosis from pericarditis very difficult. As a rule, the general condition of the patient, and a moderate heart rate with the absence of pain, will suggest that such a serious complication as pericarditis is not present.

Apart from the above physical signs the condition is of no significance, and usually disappears in a day or two.

A steam tent is sometimes necessary for the treatment of bronchitis. We endeavour to retain patients for ten days at least.

TREATMENT BY OPERATION.

TIME OF OPERATION.

The best time is as soon as possible after the patient has recovered from the initial shock, and with us has averaged about six hours after admission.

WOUNDS OF THE SOFT PARTS.

If nothing further be done, wounds of the soft parts, unless small and clean—for example, rifle bullet wounds—should be excised, because otherwise they will suppurate, and infection will spread along the track of the missile into the pleural cavity, giving rise to empyema.

FRACTURE OF RIBS.

Excision of the wound of the soft parts leads the surgeon to the ribs. More often than not the ribs or scapula are broken, and whether or not further operative procedure be undertaken for opening the chest, the splinters of bone should be removed, ragged ends of rib cut clean off, and all dead tissue excised.

Examination of the wound in this way may reveal either a bleeding intercostal artery or a large hole, hitherto unsuspected, leading into the chest, and a finger introduced into the pleural cavity may discover splinters of bone, free or sticking into the lung. Such splinters should be removed, for we believe that they play a great part in the production and maintenance of infection.

At this stage the case has been converted into one of open haemothorax; if it is decided not to open the chest

further the blood should be evacuated as far as possible by rolling the patient on to his side and then the chest should be closed in layers—pleura to pleura, muscle to muscle, and skin to skin. When there is a deficiency of pleura, muscle should be brought over the gap; where there is a deficiency of pleura and muscle, even if a flap has to be cut, skin should be brought over the gap. The chest must be closed.

RETENTION OF LARGE FOREIGN BODY.

By a large foreign body we mean a shell fragment about one inch by half an inch, with which are associated, as a rule, splinters of undriven rib and clothing; we do not include a rifle bullet.

It will be understood from this that we attribute much more importance to infection and damage caused by the missile than to the retention of the foreign body itself. But if the missile lies free in the pleura, or projects into the pleura either from the lung or the chest wall, it should be removed.

When it is decided that the removal of a retained foreign body is necessary, the operation may be undertaken either through the wound or by fresh thoracotomy. If the route chosen is through the wound, the procedure undertaken will be that detailed above for the excision of a wound, but instead of the removal of the broken ends of rib a resection of four inches will be necessary.

The choice of route for removal of a retained foreign body depends upon its position relative to the wound of entry. Where possible, thoracotomy through the wound is preferred, because in any case the wound has to be excised, and less damage is done to the chest wall.

A fresh thoracotomy may be done by resection of four inches of rib, or by an incision in the intercostal space. The easiest route is probably *via* the fifth rib in the mid or anterior axillary line; by this means, with the insertion of a retractor, any part of the pleural cavity can be reached.

On looking into the chest thus opened, the damaged lung can be seen, and the foreign body may be immediately visible; if blood obscures the view, it should be removed by rolling the patient or by mopping. If not visible, the foreign body may be sought by inserting the hand into the pleural cavity, and may be removed through the wound of entry into the lung, or by a fresh incision into lung tissue.

Lung tissue may be incised without fear, because any fresh bleeding following incision is easily controlled by suture. Continued bleeding from the lung is exceedingly rare, and in the few cases observed was due to inability of the lung to collapse, either from adhesions or splinters of bone. Early operation, even within twelve hours, with evacuation of the haemothorax, does not cause recrudescence of bleeding.

When readily accessible the wound of the lung should be cleansed either by excision or by wiping with gauze, it should always be sutured, because, if left open, organisms can pass from the lung into the pleural cavity, and there is evidence that the lung is capable of dealing satisfactorily with infections—gas gangrene of the lung, for example, is of very rare occurrence.

ABDOMINO-THORACIC INJURIES.

Injuries involving both the chest and the abdomen are not infrequent, either as the result of a single or multiple missiles. When a missile has traversed both chest and abdomen the diaphragm is necessarily injured and abdominal viscera may protrude into the pleural cavity. As efficient repair of the diaphragm can only be obtained from above it is better in such cases to open the chest first, replace the abdominal contents, suture the diaphragm, deal with the chest as already indicated, and then, if there is evidence of injury to the hollow viscera, laparotomy may be performed.

The passage of a small missile through the diaphragm may not necessitate repair; in such a case, with evidence of injury to hollow viscera, the abdomen is afforded preferential treatment.

Similarly, with multiple injuries involving both chest and abdomen, it is probably better to deal with the abdominal injury first, but when the patient's condition allows the chest injury should be dealt with in addition, even if only a minimum can be done.

INFECTED HAEMOTHORAX.

We believe that the incidence of infection will be diminished when more attention is paid to complete excision of wounds of the chest wall. But infection of the intrapleural contents occurs also in cases of small clean wounds where no foreign body is retained, and also after excision of the parietal wounds, and particularly in men who have lost a large quantity of blood.

The infecting organism and resulting toxæmias vary considerably; in our experience, while a mixed infection is always severe, the anaërobic bacilli are among the most benign, and the streptococci—especially if haemolytic—are the most dangerous. Evidence of infection is rarely seen before the third day after the wound and may be delayed for many days. The only certain evidence of infection is either a positive bacteriological finding or the removal of stinking fluid. By clinical signs it is often possible to diagnose the presence of infection before organisms can be detected by the bacteriologist.

As soon as infection is proved or suspected, the essential treatment is to empty the chest of all infected blood and clot. This cannot be done by aspiration, and must be done by open operation.

The common practice has been resection of one inch of rib and insertion of a tube. Provided that the operation is done within a few days of the receipt of the wound, we believe that it is better to do a wider resection, by which means all clot can be removed and the pleural cavity washed out with eusol, and then to close the chest in layers.

This method offers the following advantages:

1. The chest may remain closed, the organisms not developing.
2. The lung is allowed to expand, and adhesions may form which will prevent complete collapse, even if the pleural cavity is subsequently drained.
3. Respiratory distress is much less with the closed chest.

The condition of the pleural contents can be determined by post-operative needling. If infection persists the chest must be opened and drained; this can be done by the removal of sutures from the resection incision, provided only that the incision has been made in a suitable place, that is, low and postero-laterally.

ANAESTHETICS.

Patients bear operation well, and take a general anaesthetic satisfactorily. We believe that any patient on whom an intrathoracic operation is to be performed should have a general anaesthetic.

We have generally administered chloroform through a Shipway's apparatus. One side of the chest can be opened without danger of respiratory failure, except when there is damage or collapse of the opposite lung, as evidenced by inspiratory retraction of the chest wall.

A short experience of gas and oxygen anaesthesia leads us to the belief that it is an ideal anaesthetic for such cases.

CIRCULATORY DISTURBANCES.

When one side of the chest is open, either as the result of an operation or the original injury, and also in cases of pneumothorax, respiratory variations in pulse volume are very marked. During inspiration pulse volume diminishes and pressure falls; the pulse may become imperceptible. This condition is not of serious import, and, when the chest is closed, diminishes considerably or disappears altogether. We mention it as it is apt to alarm the anaesthetist.

CONTRAINDICATIONS FOR OPERATIONS.

1. Shock and collapse, such as would be contraindications for any surgical procedure.
2. Small clean wounds, without evidence of serious intrathoracic injury.
3. Retention of a small foreign body in the lung or mediastinum. In our experience of early convalescence the foreign body, if small, may be disregarded. We are not in a position to speak of the ultimate results.
4. Collapse of the opposite lung, as indicated by inspiratory retraction of the chest wall on the side opposite to the wound. In this condition an anaesthetic and opening of the chest may be fatal.

In one of our cases a plug of blood and mucus had been sucked into the bronchus of the opposite lung, and the patient died of respiratory failure when the injured side of the chest was opened.

OPERATIVE TECHNIQUE.**THORACOTOMY THROUGH THE WOUND.**

The first essential is the complete excision of the wound including the skin, muscles, and broken ends of rib. This having been completed, the chest should be opened with fresh instruments. An incision is made from the edge of the wound through the skin along the line of the broken rib, either forwards or backwards, to obtain the best access to the cavity of the chest. Then the muscles are incised down to the rib, retracted, and the periosteum incised along the middle line of the exposed rib. Along this line the periosteum is stripped off with a rugine. A Doyen's periosteal rib elevator is then slipped in and the periosteum entirely separated. The bone is then cut through with a pair of rib shears or bone forceps and removed. To allow free access to the pleural contents and insertion of the hand it is necessary to take away four inches of rib.

The posterior layer of periosteum of rib with the parietal pleura attached is next incised with a pair of scissors along the middle of the gap. Then a retractor or rib spreader is inserted and the chest opened widely.

THORACOTOMY BY FRESH INCISION.

As previously stated, this operation may become necessary when thoracotomy through the wound will not allow access to the injured portion of lung, for instance, when the wound is in the lower and posterior part of the thorax and the foreign body near the hilum or in the upper lobe of the lung.

Choice of Route.

Resection of four inches of the fifth or sixth rib in the anterior axillary line gives a good exposure of the thoracic contents, and if there are no other considerations this is probably the best and easiest route to follow. It has to be remembered, though, that if drainage of the pleural cavity has to be performed later on, it cannot be done effectively through this incision. Therefore, if the nature of the wound and missile is such as to indicate probable future infection, it may be advisable to choose a lower rib and make the incision more posteriorly.

Operation.

A six-inch incision is made along the line of the selected rib, and continued down to the periosteum, which is stripped off the anterior surface with a rugine. With rib elevator and shears four inches of the rib is resected. The posterior layer of periosteum with the parietal pleura attached is then incised along the whole length of the middle of the gap, and the retractor or rib spreader inserted.

This is the method we have usually adopted with good results.

Alternative Methods of Opening Thorax by Fresh Incision.

1. Incision through an intercostal space, with or without section of one or two costal cartilages. A good exposure may be obtained by this method, provided the patient is young and has elastic ribs. We have found some difficulty in closing the chest efficiently afterwards, and prefer the resection method.
2. Before the war the pleuro-costal flap method was advocated. This is unnecessary, and prolongs the operation.
3. Cowell has suggested that the rib should be split along its longitudinal axis. This method merits trial.

PROCEDURE WITHIN THE THORACIC CAVITY.

After the chest has been widely opened, either through the wound or by fresh incision, it is advisable to remove the blood from the pleural cavity, first, because it is easier to see what has to be done, and, secondly, because removal of the blood relieves respiratory difficulties by lessening pressure on the mediastinum. The blood can be removed

by rolling the patient on to his side. Probably, however, it is better to do it by swabbing with gauze and scooping out the clot with the gloved hand; less disturbance is caused to the patient by this method.

This done, the gloved hand should be inserted into the pleural cavity and swept round in order to detect and remove any splinters of bone which may be lying free, or the missile and portions of clothing. These are most likely to be found in the pleuro-diaphragmatic reflexion.

Next the foreign body, if retained in the lung, may be detected by the fingers, and with the aid of two pairs of lung forceps the affected area is brought into the opening of the chest. The lung can be handled as easily as a coil of intestine, and without causing a great fall of blood pressure.

TREATMENT OF THE WOUNDED LUNG.

A foreign body, when present, seems to lie generally near the surface of the lung, and can easily be removed; if necessary, a small incision may be made through the lung substance.

The hole in the lung should now be explored for splinters of bone and shreds of clothing, and cleansed as far as possible by swabbing. When there is a large ragged wound, and it is anatomically possible, a wedge of lung may be removed, or the edges of the hole clipped with scissors.

In any case, whether the wound is excised or not, it should be closed by catgut sutures, in either one or two layers, according to the depth of the wound. Bleeding is easily controlled by such suture.

CLEANSING OF THE PLEURAL CAVITY.

In most cases it is only necessary to cleanse the pleural cavity by swabbing it dry and clean. If, however, there has been much soiling, it is advisable to wash it out with either warm saline or eusol. In any case, however, the chest should be left dry, an essential factor in the early expansion of the lung.

CLOSURE OF THE CHEST.

Whether the operation has been performed through the wound or by fresh incision, the chest should always be closed. The relief afforded the patient is instant and marked. An attempt should be made to repair the chest wall in layers—pleura to pleura, muscle to muscle, and skin to skin.

Where a large hole has been blown through the chest wall it may be impossible to make the edges of the pleura meet; in that case muscle should be made to cover the gap, even if a flap has to be cut. Finally, the skin should be closed by interrupted sutures. In the majority of cases healing will be by primary union.

INSTRUMENTS.

The following instruments have been found of service:

(1) A self-retaining retractor or rib-spreader. This is of great value, and allows easy manipulation of the pleural contents. We use one obtained from Schaefer's, instrument makers, of Berners Street, London, W. Another pattern, Tuffier's *écarteur*, can be obtained from Parisian instrument makers.

(2) Doyen's periosteal rib elevator, and (3) Doyen's rib shears, can both be obtained from the ordinary English instrument makers.

(4) Duval's lung forceps (Pince de Poumon à Duval), Maison Collin, Rue de l'École de Médecine, Paris.

(5) An electric head lamp.

Table of Results, showing Casualty Clearing Station and Base Mortality.

Total number of cases	365
Total deaths	76=20.8%
Deaths from complications:				
Chest and head	6
Chest and abdomen	14
Chest and spine	4
Chest and heart	4
Chest and large systemic vessels	1
Chest and multiple wounds	14
Chest and lethal gas	1
Total	45

If the above 45 deaths from complications are excluded there remain 320 cases. Of these 31 died (9.6%) of chest injuries.

Causes of deaths from chest injuries:

Shock and haemorrhage	19
Sepsis	10
Bronchitis	2
Total	31 = 9.6%

A NOTE was published last week on the experiments of Hanzlik and Karsner on albuminuria and haematuria after the use of salicylates. We have since received a report of a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, on October 26th, at which Dr. Boxwell mentioned the case of a soldier in whom an attack of haematuria immediately followed the exhibition of sodium salicylate on two occasions. Blood was present at first, but later the corpuscles disappeared, though the urine remained a deep brown colour for some time. The spectroscopic appearances were negative. At the same meeting Dr. Wallace Beatty described a case of sporotrichosis in a boy aged 15½ years, a worker in a brush factory, who was injured on the front of the wrist by a piece of bass. Professor McWeeney confirmed the diagnosis by cultures. This, it was stated, was the first case recorded in Ireland. Dr. Walter G. Smith pointed out that the condition might be confounded with syphilis, tuberculosis, and purulent inflammation. It could be cured by potassium iodide.

Lectures
ON
THE ANATOMICAL AND PHYSIOLOGICAL PRINCIPLES UNDERLYING THE TREATMENT OF INJURIES TO MUSCLES, BONES, AND JOINTS.

GIVEN AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND,
NOVEMBER–DECEMBER, 1917.

BY
PROFESSOR ARTHUR KEITH, M.D., F.R.S.,
CONSERVATOR OF THE MUSEUM.

II. JOHN HILTON'S PRINCIPLES OF TREATMENT.

Abstract.

IN the spring of 1862 John Hilton completed in the theatre of this College a series of lectures which, when published in a book under the title of *Rest and Pain*, won an enduring place in the minds and hearts of medical men. I have our College portrait of him to show what kind of man gave those lectures here fifty-five years ago. "Rest and pain" is a title with more than a touch of romance in it; it prepares you to expect the finely chiselled face of a poet; but the man who wore those vivid and incisive lectures from materials freshly gathered at the bedside had nothing of the poet about him. His is a flat, rotund, plainly moulded, robust, and honest face. His contemporaries tell us that he had the outward appearance of a dapper, prosperous city man. There is nothing at all of the student's cast of countenance about this man whose skilful practice we are to follow. There is no trace in him of the society man; he cold-shouldered all the world save the few he selected for associates and friends. He could be, and often was, overbearing, rude, and mordantly sarcastic. But we shall see that he faced adversity with a brave heart, asking no favour and having no fear of any man, knowing well that he had that to sell which the world must buy, not at its, but at his price.

Having thus introduced John Hilton when he had established for himself a sure place in British surgery, I propose now to turn to his earlier years, and watch his growth in knowledge. Hunter served the apprenticeship to his life's career in the dissecting room; so did John Hilton. Hunter's dissecting room was in Covent Garden; Hilton's lay in the Borough, beyond the south end of London Bridge. In the year 1824, when Hilton, a lad of 17, came from Chelmsford Grammar School to commence his medical studies, the twin hospitals of St. Thomas's and Guy's were cheek by jowl in the Borough. They had a common dissecting room when Hilton attached himself to Guy's. He was born at Castle Hedingham, in the upper reaches of the Colne, in North Essex, as pure a Saxon settlement as is to be found anywhere in England. He was a Saxon in build of body and in frame of mind. His people were apparently not well off, for Hilton could not afford to pay the surgeon-pupil's fee which would have secured for him the privileges of climbing to the highest position in his hospital. Hunter had been dead more than thirty years when Hilton entered the Borough in 1824, but his name and teaching were kept green there by two ardent Hunterian pupils and disciples, Henry Cline and Sir Astley Cooper. Hilton could begin where Hunter left off.

In 1828, at the age of 21, having taken the diploma of this College, he entered the dissecting room of Guy's Hospital as demonstrator of anatomy, and there and in the post-mortem room he was destined to abide and work for seventeen long years, when, in 1845, at the ripe age of 38, he was appointed assistant surgeon to the hospital and lecturer on anatomy. Like Hunter, he served his apprenticeship to surgery in the dissecting room. Only it was a different apprenticeship. There was a home in the suburbs, but no experimental station in the suburbs, no sedulous cross-examination of freezing eggs, incubating chicks, or sensitive hydra to yield the secrets of life. Certain things had happened since Hunter's death which influenced the men of Hilton's time. Archdeacon Paley had cast a spell on the marvellous mechanisms of the human body. It became the chief duty of the anatomist

to discover the utility and design of every one of its many structures. Hence we find Hilton in the dissecting room seeking continuously for an explanation of the arrangement and use of its various parts. He turned his attention to the distribution of arterial trunks, and sought for a functional—or, as his contemporaries would have phrased it, a teleological—explanation. For him the internal maxillary became the "artery of mastication"; it was designed and laid down to supply all the parts concerned with the jaws and the muscles which moved them. Its large middle meningeal branch, far from proving his thesis to be wrong, proved its truth, for did it not supply that temporal area of the skull which provided a firm basis for the largest of masticating muscles—the temporal? On the same basis he explained the distribution of the branches of the subclavian arteries; they were "respiratory vessels" destined to supply muscles and bones concerned in the act of respiration. The coeliac axis was "the artery of digestion"; it supplied the organs immediately concerned in that act. We see him hot foot in the application of the doctrine of utilitarianism to the structure of the human body.

Certain events which occurred just before and just after he became demonstrator at Guy's in 1828, turned his attention to the manner in which nerves are distributed; these were the discoveries of Charles Bell and of Marshall Hall. On becoming a medical student Hilton could not have escaped the glamour of the doctrine which Charles Bell was still preaching from the precincts of Piccadilly; for the first time a utilitarian explanation of nerve roots had been given; for the first time it was shown that nerves going to muscles were compound in nature; they contained fibres which carried messages from the brain, and also others which carried messages to the brain. It was late in 1832, just as Hilton was commencing his fifth year in the dissecting room, that Marshall Hall, working in a laboratory extemporized in his Bloomsbury home, announced to an incredulous world his discovery of the "reflex"—or, as he preferred to call it, the "excito-motor"—function of the spinal cord. Hilton never understood the nature and full significance of Marshall Hall's discovery, but nevertheless it bent him towards the investigation of nerve distribution. Hence we find him dissecting out the exact distribution of the laryngeal nerves; he shows that the nerve which furnishes the mucous membrane of the larynx with sensory fibres also supplies the muscles which are situated beneath the membrane with motor fibres. For him that observation became the basis of a law—the nerve which supplied the motor power of a part also served the sentient surfaces connected with that part. For him the nerve trunk became the functional element. He preferred to work on what seemed a solid anatomical basis than trust himself to the intangible "excito-motor" theory of Marshall Hall.

He applied himself to the investigation of the nerve supply of joints. In the hip he observed that the three nerve trunks—anterior crural, obturator, and sciatic—which supply the muscles which act on the joint, also send sentinel branches to the joint itself. By such an arrangement he believed a consensus of action was obtained: the articular sentinels kept their muscular colleagues informed as to the condition of parts in all stages of a movement. In the knee-joint he found further confirmation of his belief: the obturator nerve sent a twig to the knee-joint because the gracilis—an obturator or adductor muscle—acted on that joint. For the same reason the nerves which supplied the extensors and flexors of the knee also supplied the joint. At the knee-joint he was able to go a step further: the nerves which supplied a joint also supplied the sentient skin which enclosed and protected the joint.

As regards the knee-joint this theory presented a difficulty: the internal saphenous nerve which furnishes a large branch to the skin of the knee was distributed chiefly in the leg and foot. A nerve which observed his theory should not do a thing like that. Hilton's was an eminently logical and practical mind, and this seemed an exception to his law of "consensual distribution," he turned to its support in the following manner. The sartorius muscle acted not only on the knee-joint, but through its fascial insertion on the whole of the inner side of the leg. It was necessary, he conceived, that a nerve of a muscle group should supply the skin over its entire area of action, and hence the extension of the distribution of the internal saphenous nerve to the inner side of the leg.

He supported his contention by an appeal to the upper extremity: the posterior circumflex—the nerve of the shoulder-joint—sent cutaneous branches beyond the deltoid because that muscle had an insertion to the fascia of the arm; the musculo-cutaneous of the arm sent a branch to the forearm because the biceps, by its fascial insertion, acted on the forearm. In the dissecting room, and afterwards in his surgical lectures, we shall often find him straining a hypothesis far beyond its breaking point. But right or wrong, it was just because he tried to explain appearances and kept his eye ever on the alert that he became a power in British surgery. In 1839, while still engaged in these dissecting-room researches, he was elected to the Royal Society at the age of 32.

We are now to follow Hilton when he is launched in the field of surgery, at the ripe age of 38, and watch him apply, in the treatment of joints, muscles, and nerves, the knowledge he had gained during the seventeen years of continuous labour in the dissecting and *post-mortem* rooms. In some respects he is to out-Hunter Hunter. He never leaves us a moment in doubt as to the rôle the surgeon is to play in the treatment of disease. He must be nothing more and nothing less than Nature's humble assistant. At the end of his fourteenth lecture, when his experience was ripe, he summed up his philosophy in these words:

By regarding this subject of physiological and mechanical rest in what I conceive to be its proper professional light, the surgeon will be compelled to admit that *he has no power to repair directly any injury*. It will induce him to acknowledge in all humility that it is the prerogative of Nature alone to repair the waste of any structure. He will thus realize that his chief duty consists in ascertaining and removing those impediments which obstruct the reparative process, or thwart the effort of Nature, and thus enable her to restore the parts to their normal condition.

Hilton had the power of putting into words thoughts which were beyond the power of Hunter's utterance. Nor can I resist to quote here another instance from his third lecture which shows not only his opinion of the surgeon's place, but gives a glimpse of his humanity and his command of idiomatic English, learnt while a boy at Castle Hedingham.

A surgeon from the country lately came to my house with a patient. He said: "I want to consult you about a young lady who has a diseased toe." With her was a relative, an elderly gentleman, a very kind-hearted man, who thinks himself a good surgeon and goes about doctoring people, sometimes doing harm and sometimes perhaps a great deal of good. He is very fond of animals, and has a number of pets. After I had examined, with the surgeon, the lady's toe, the elderly gentleman said: "Well, Mr. Hilton, what are you going to do to cure this young friend of mine?" I said: "I think I shall put a splint on the foot and keep the toe quiet, attend to her general health, and Nature, in all probability, will do the rest." I then said to him: "What led you to adopt the occupation of a philanthropic surgeon?" "Well, Mr. Hilton," he replied, "I will tell you. Some years ago I caught a live mouse in a trap. . . . Then I thought to myself, 'This mouse must have had difficulties in the treatment of its injuries; and—' Interrupting his story, he said, "I hope you won't be offended at what I am going to say?" "No," said I, "not in the least." "Well," he continued, "I said to myself, surely this mouse, although it is cured, never had a physician or a surgeon? I agree with you, Mr. Hilton, that Nature is a very valuable surgeon."

This vivacious passage makes it very clear that Hilton considered the surgeon's first duty was to give the injured parts rest. It was by means of rest that he could best help Nature. The therapeutic value of rest has been recognized by surgeons of all periods. It constituted the fundamental principle of Hunter's practice, but while Hunter gave it a place at the end of a paragraph, Hilton made it the heading for a new chapter. He used his knowledge of the structure and function of the body as a means to discover how parts could be rested. He began by applying his dissecting-room investigations to the treatment of inflamed joints. "Why is an inflamed joint fixed and flexed?" he asks. His answer is that

the irritated or inflamed condition of its interior (say the knee-joint) involves all the articular nerves, excites a corresponding condition of irritation in the same nerve trunks which supply its extensor and flexor muscles. The flexors, by reason of their superior strength, compel the limb to obey them, and so force the joint into a *flexed condition*. . . . The muscles, indeed, appear to be told, through the medium of the nerves of the interior of the joint, that its articular structures are over-taxed; the antagonistic muscular forces of the joint being thus *involuntarily* excited, the joint is at once rendered rigid and stiff for the purpose of keeping it at rest. . . . The flexors act

unceasingly day and night apparently without rest, and especially declare their mischievous assiduity by the wakeful slumbers and disturbed sleep of the patient.

The surgeon's first duty was therefore to give the exhausted muscles rest by removing the source of their disturbed action—the stimulus which arose within the diseased joint at each movement. That could be done in only one way: if we would set the muscles which act on the knee-joint at rest, then we must prevent the articular nerves of the joint from being irritated by the pressure and friction which result from every movement—particularly involuntary movements. There was only one way—rest. But not the rest given by a general instruction to patient, guardians, or nurse—as Hunter gave it; not rest in homoeopathic or intermittent doses, but a long continuous course. The methods used to secure such rest must be founded on a sure anatomical and physiological basis, prescribed with precision and carried out meticulously, until Nature had effected a cure. The application of splints was his chief means of securing physiological rest of joints. We shall have occasion later to allude to the designs he employed; his service to surgery lies not in the forms of splints he recommended, but in his insistence on their unremitted application.

In passing at once to Hilton's chief work—his application of the principle of rest to the treatment of diseased and injured joints—I have failed to do justice to the solid basis of observation on which he based his practice. He had noted, as had many a surgeon before him, that spasm departed from the orbicularis palpebrarum when the irritant, whatever form it might assume, was removed from the eye; that the removal of a fish-bone from the throat set the pharyngeal muscles at rest, and that the extraction of a calculus relieved spasmodic contractures of the bladder. To obtain rest the irritant had to be removed. He construed the word "rest" in a wide sense. You will recall this case:

That of a man who had received a blow on the chest from a fall upon the part. I could find no fracture of the ribs, but observed that the patient had a most worrying wife. I suggested to the physician that the sole cause of the pain was in all probability produced by the patient constantly moving the injured or bruised soft parts by using his chest and lungs in speaking. All I recommended was that he should hold his tongue and have his chest bandaged. I requested that his wife should not say a word to him. From that time he got quickly well by local rest.

The instance shows us that he used the word "irritant" as well as "rest" in a wide sense. He considered that the false membrane which forms on an acutely inflamed mucous surface, the scab which spreads over an open wound, the exudates which appear on the surfaces of inflamed serous membranes, were Nature's means of protecting these parts from irritation and thus providing them with rest. It was to give rest that he excised painful cicatrices, and cut the nerves which supplied the painful points of irritable ulcers. He rested the heart by confining the patient to bed, and elevated the extremities to rest their vessels. He relieved tension to give rest—the tension of abscess, of stretched nerves, and muscles. Occasionally he resorted to tenotomy to give a spasmodic muscle rest. One series of cases which he treated by rest for the relief of tension of nerves is now of particular interest to us. They are cases which Hilton described as "cervical exostosis," but which we now know are due to the pressure of the lowest trunk of the brachial plexus against the uppermost rib—usually one attached to the seventh cervical vertebra. Hilton treated such cases by rest—rest in the recumbent position, which relieved the suspensory muscles of the shoulders and lifted the nerve trunk from the point of pressure. Whether we agree with Hilton in all his interpretations of Nature's intention or not, we must admit that he sought for and obtained a rational basis for his means of treatment—one founded on the facts of Anatomy, Physiology, and Pathology.

In his scheme of therapeutics action finds no part—neither active movements nor passive movements are considered. "No counter-irritation, none of the old horse-doctoring style of treatment, no setons, issues, or painful applications of any kind," is his verdict as regards ancient and widely established practices. He gives us no reason: simply his dogmatic assertion. He warns his readers of the danger of "walking off" muscular pains and stiffnesses. He had never seen long-continued rest produce harm:

healthy joints which had been confined for months came out undamaged from months of continuously enforced rest. Yet there is one of his observations which does bear on the utility of movement in preventing ankylosis. He remarks on the rarity of ankylosis in the joints between ribs and spine. They are joints at which movements go on unceasingly throughout life. But he refused to associate their freedom from disease and from ankylosis with their inability to assume a position of continuous rest.

If Hilton's first service to surgery was to give "rest" a foremost place in the means of treatment, his second service was to give "pain" its rightful place in the means of diagnosis. He was a teleologist; he regarded the human body as a specially designed machine provided with a sense of pain to serve as a signal of disease.

I conceive that pains situated on the surface of the body, and associated with some abnormal state of an internal viscus, must be looked on as a beneficent provision, enabling us by external pain to receive the information and to appreciate slight organic changes or derangement of function of the internal viscera.

That statement of Hilton's was particularly directed against those who hide their ignorance by tracing all obscure pains to rheumatism and gout. In his opinion, pain was provided by Nature to guide the surgeon to the seat of disease; a knowledge of the distribution of nerves and the manner in which the nerve system acted was the means by which the surgeon was to obtain a correct diagnosis. Pain was a demand for rest. He made certain observations which throw some light on the production of pain. In a case where the ulcerated articular surface of the astragalus was exposed, he made his pupils note that when he merely touched the ulcerated area the patient felt nothing, but when he pressed it there was pain. Pressure gave pain; rest relieved it. In another case, one of necrosis of the tibia, he showed how pressure on the artery above the seat of disease diminished pain, while pressure on the veins increased it. Pressure within the capillaries caused increase of pain.

I should give a very imperfect picture of the foundation of Hilton's methods of treatment were I to omit his inquiries into pathological conditions. I need only cite two cases to show you that he sought in every case, before commencing treatment, to realize the exact nature of the deeply seated lesion; he never allowed an opportunity to escape which would yield him information. The first case I shall cite is this:

A young gentleman, 18 years of age, living in Islington. On a Sunday evening, returning from chapel, wearing a very narrow high-heeled boot, walking at the edge of the pavement, his left foot turned inwards with a sudden jerk, and he exclaimed to his sister, who was with him: "Oh! I have twisted my foot; I never had such a dreadful wrench before." I saw him on the following Sunday with Dr. Billingham, and I then came to the conclusion that he had sustained some injury to the lower epiphysis of the tibia, for, upon close examination, I found the ankle-joint free from mischief. Hilton advised rest. Some days later, when he was visiting patients in the city, he learnt by accident that the young man was dead. He set out for Islington. "The hearse was at the door, so that I had only time to unscrew the coffin and examine the leg. I took away the bit of tibia; it fairly rewarded me for the trouble. There was a laceration between the shaft of the tibia and its lower epiphysis—precisely the spot where the boy had the first sense of pain on the Sunday morning."

Hilton thus provides us with an everlasting example of the manner in which surgery is made into a rational art. The second case I am to cite is equally instructive.

A man, going across Blackheath rather the worse for liquor, fell down or jumped six or eight feet into a gravel pit, and, alighting on his feet, his leg was very severely broken. I amputated the leg below the knee. On examining the ankle-joint, which had apparently not been injured, I found the articular cartilage upon the astragalus actually depressed at one part, and at another I saw within it a large black, deep patch.

This patch Hilton cut out and brought to my predecessor at this College—Mr. Quekett—who cut microscopical sections of it, and found that it was due to an extravasation of blood beneath the articular cartilage. In this instance Hilton provided us with a kind of observation of which we still stand much in need—the lesions of joints which we classify under the generic term of "sprain."

GASTRO-INTESTINAL SEPSIS A CAUSE OF MÉNIÈRE'S SYMPTOMS.

BY

T. MARK HOVELL, F.R.C.S. EDIN.

SINCE Ménière's paper dealing with a set of symptoms produced by hæmorrhage into the labyrinth, and consequently producing an incurable form of deafness, was published on February 9th, 1861, this set of symptoms, with which his name has been associated, has conveyed to the medical profession at large the idea of a condition of the ear for the relief of which little can be done.

Although aural surgeons of late years have clearly drawn the distinction between Ménière's disease, or the class of cases to which Ménière referred in his paper, occurring suddenly in patients without previous ear trouble, and Ménière's symptom complex occurring in patients suffering from an affection of the middle ear—which condition for many years I have preferred to call by the simpler term of Ménière's symptoms—the distinction is not as yet universally understood in the profession, and there is in consequence a tendency, except with aurists, for any patient suffering from the group of symptoms which Ménière described to be regarded as having an incurable ear disease, so that palliative treatment is all that is possible.

It is not my intention now to deal with the cases in which the symptoms are produced by syringing the ear when perforation of the drumhead exists, or by quickly rotating the patient, or to an extension of suppuration to the labyrinth, or are found in the course of an acute disease from inflammation or infective processes extending to it, or with the attacks of giddiness and tinnitus which occur sometimes as part of the vasomotor disturbances which accompany the menopause, or any of the cases in which the cause is obvious, but to confine myself to those which occur in patients suffering from middle-ear disease and come on without the reason being apparent.

Having noticed a similarity in the general condition of patients who become affected in this way, I began to pay close attention to the matter, and found that the treatment adopted not only greatly diminished the frequency and severity of the attacks, but in some cases practically freed the patients from this distressing condition.

Many of the patients I have seen had the following conditions present at the first visit: A furred tongue, congested pharynx, nasopharyngeal catarrh, hypertrophic rhinitis, flatulence frequently causing a considerable amount of distension, and constipation, although sometimes the motions were broken and light coloured. Several patients have told me that previous to an attack the motions have been noticed to be especially offensive.

With these symptoms it did not surprise me to find often, although not invariably, the blood pressure high, for toxæmia due to intestinal sepsis is a common cause of increased blood pressure, and as might be expected some dilatation of the heart often existed, although this symptom was not always present. It is not customary habitually to examine the size of the heart by gently percussing the chest wall whilst a stethoscope is held against it; if this were done the transition of sound from clear to more dull, indicating that the cardiac area has been reached, could easily be appreciated, and dilatation would be found to be far more often present than is now generally supposed.

Although I have only mentioned toxæmia due to intestinal sepsis, oral sepsis due to pyorrhœa, decayed teeth, crowns, or bridges must not be overlooked, or any other condition which might tend to produce this result.

With the patient in the state which I have described, it is not surprising that closure of the Eustachian tubes is usually present when Ménière's symptoms exist, for gastro-intestinal derangement is a common cause of congestion of the pharynx and nasopharyngeal catarrh and consequent closure and catarrh of the Eustachian tubes. Nor is it to be wondered that tinnitus and giddiness are found when toxæmia is present, these symptoms being more the result of this condition than caused by high blood pressure when it exists.

* A paper read before the Otological Section of the Royal Society of Medicine, November, 1917.

With the condition I have described present it is obvious that in many instances it would add materially to the comfort and well-being of the patient if the set of symptoms known as Ménière's were to convey in the first instance the impression of the existence of gastro-intestinal derangement rather than as at present an incurable condition of the ear; for with the former basis thoughts would travel to gastro-intestinal antiseptics, medicines for reducing blood pressure and correcting digestive derangement, and as to the advisability or otherwise as a preliminary measure of washing out the stomach with an alkaline solution in the usual manner by means of a funnel attached to a flexible rubber tube. In some cases I have had a specimen obtained from the stomach during fasting and a vaccine prepared and administered as an adjunct to other treatment.

With regard to blood pressure, I may mention in passing that a solution of adrenalin chloride taken internally is by many supposed to increase blood pressure, but in reality a small dose reduces it, and three to five drops with a little dilute hydrochloric acid, appropriately flavoured, makes a pleasant and useful mixture; but no medicine given with the object of reducing blood pressure will yield satisfactory results unless the intestinal tract is restored to a healthy condition, and as a first step to medicinal treatment I am in favour of a full dose of castor oil.

Although the removal of the cause is essential for the successful treatment of the case, local measures also give material relief; the most important of these is to restore the patency of the Eustachian tubes. In many instances the mere injection of air into the tympanum lessens the distressing symptoms, but I find that for permanently restoring the patency of the Eustachian tubes the injection into them through a catheter of a few drops of collosol argentum is often shortly followed by a beneficial result. The nozzle of the syringe which injects the drug into the catheter must not fit the catheter tightly, or the drug might be forced directly into the Eustachian tube instead of being sent into it in the form of a spray by air pumped from an air-bag, the nozzle of which closely fits the catheter. To lessen the nasopharyngeal catarrh, collosol argentum or collosol iodine is useful, sprayed directly backwards through the nostrils by an all glass or vulcanite spray producer so that it reaches the nasopharynx and the orifices of the Eustachian tubes.

The injection of a few drops of collosol argentum, or in some cases of collosol iodine, into the Eustachian tubes with the object of restoring their patency, is useful not only to patients suffering with Ménière's symptoms but also in closure of the tubes to Valsalva's inflation due to any cause. I have seen many instances in which this treatment greatly relieved or removed tinnitus when closure of the tubes existed, although the patient may have been suffering from incurable deafness due to sclerosis or other conditions. Whether in this case the tinnitus is due to a congestion produced by long-continued closure of the tubes, and the mere restoration of the patency by removing this causes the tinnitus to subside, or whether it is due to the tissues being affected by the drug, I am unable to say. This simple method of removing the tinnitus, often of old standing, which is frequently the patient's chief trouble, is worth remembering, as tinnitus has always been a difficult symptom to get rid of; even the more troublesome treatment by ionic medication, when it gives relief, is not always followed by complete cessation.

I have found collosol argentum also useful for stopping earache, and usually apply it for this purpose by placing the patient with the meatus of the affected ear upwards and then filling it with the drug and allowing it to remain there. Collosol iodine or collosol mercury should not, I have been told, be given in conjunction with arsenic, as mercurial poisoning or iodism respectively quickly follows. I have had no personal experience of the result of these drugs being administered together or in close succession.

AN institute for soldiers blinded in the war was recently opened at Salerno. Its establishment is due to the initiative of Professor Carlo Carneci, director of the local technical school. There was no ceremony, but an interesting feature of the occasion was a musical performance by Professor Marinuzzi, who is himself blind.

THE PARAFFIN TREATMENT OF BURNS.

BY

LIEUT.-COLONEL ALFRED J. HULL, F.R.C.S.,

ROYAL ARMY MEDICAL CORPS.

THE introduction of new non-irritating antiseptics has led to several modifications in the paraffin treatment of burns.

Various preparations of paraffin have been made under my direction, containing acriflavine, brilliant green, chloramine-T, etc., dissolved in the paraffin base. These preparations have been given a very extensive trial. Another direction in which the new antiseptics have given scope for improvement has been the treatment of the burn by an antiseptic before the application of the paraffin. The results following this modification have been so satisfactory that we have adopted it as a routine method.

The method of application of the paraffin base is the same in all cases. The burn is first of all washed with normal saline (1 in 1,000 acriflavine solution or proflavine has now been substituted). The burn is dried with gauze or an electric drier. A layer of paraffin is painted over the burn. The paraffin is applied at a temperature of about 55° to 60° C. A thin layer of wool is placed over the first layer of paraffin and a second layer of paraffin at the same temperature painted over the wool. A dressing of wool and bandage is applied over the paraffin dressing. The dressing is changed every twenty-four hours. It is important to paint or spray on a sufficiently thick layer of paraffin. If the temperature of the paraffin is too high, the layer is liable to be too thin. The efficacy of this treatment depends largely upon the mechanical effect of the paraffin. The epithelium is conserved from damage; the tissues are held at rest by a splint-like action of the dressing. The addition of antiseptics to the paraffin preparation gave better results than preparations without antiseptics. The first antiseptic to be extensively used was eucalyptus oil, which, in conjunction with beta-naphthol, is still used in No. 7 paraffin. Scarlet-red paraffin has given satisfactory results in general use, and has special indications for its use which makes it a preparation of value. Burns which have been treated with No. 7 paraffin occasionally become sluggish and present unhealthy granulations. We have therefore changed the paraffin to scarlet red paraffin when burns have become clean and shown a tendency to begin to heal. This treatment has resulted in great acceleration of healing. We have made many experiments with a view to improving the paraffin base, but no preparation has given such good results as No. 7 paraffin. Later a flavine paraffin has been extensively used, and has given satisfactory results. Paraffin preparations of brilliant green and chloramine-T have not been satisfactory from a pharmaceutical point of view, the antiseptics being difficult to incorporate in the paraffin.

Various paraffins of varying degree of melting point have been tried, but the use of paraffin of intermediate melting point does not produce so good a mechanical base as No. 7 paraffin. The dilution of a high melting point wax with vaseline and oil appears to have some special value in the treatment of granulating surfaces, and makes a better mechanical mixture. The question as to whether special paraffins (scarlet-red, acriflavine, chloramine-T) possess any particular value has been debated. It would appear that since the antiseptic can be painted on the burn before the application of the paraffin, the use of special paraffin is somewhat unnecessary. The results of acriflavine applied in the form of solution followed by the application of No. 7 paraffin have been so good that we have practically discarded the use of special preparations with the exception of acriflavine paraffin and scarlet-red.

The effect upon recovery of the application of various antiseptic solutions previous to the application of the paraffin has been studied.

Ensol accelerated the cleaning of the burn but was too irritating in its action.

Brilliant green cleaned the burns well, but if used beyond a certain stage caused light-coloured and unhealthy granulations.

Acriflavine cleans the surfaces well; whether better than brilliant green or not is doubtful, but it certainly produces a healthier type of granulation.

Scarlet-red is only used when the burns are clean and

require stimulation. A 10 per cent. aqueous solution is painted over the burn before the application of the paraffin. There is very distinct evidence that convalescence is greatly accelerated by the use of this powerful stimulus to the formation of epithelium: 1 and 10 per cent. have been tried, and in most cases the 1 per cent. has proved sufficient.

Mustard gas burns heal readily by the ordinary application of No. 7 paraffin.

The treatment giving the most satisfactory results, obviating pain, sepsis, and other complications, and which we have found generally applicable, is the preliminary painting of the surface of the burn with aqueous flavine solution 1 in 1,000, followed by the application of No. 7 paraffin. In cases of long duration scarlet-red 1 per cent. is substituted for the flavine solution. We have found rapidity of healing and minimized scarring to be greatly favoured by this treatment.

FORMULAE.

No. 7.

Resublimed beta-naphthol	0.25 per cent.
Eucalyptus oil	2 "
Olive oil	5 "
Vaseline	25 "
Paraffinum durum	67.75 "

No. 10. Red.

Scarlet-red	0.2 per cent.
Eucalyptus oil	2 "
Olive oil	5 "
Adeps lanae hydrosus	4 "
Paraffinum molle	21 "
Paraffinum durum	67.8 "

No. 11.

Scarlet-red 0.2 per cent. at expense of paraffin molle. It is difficult to get a good wax which will melt and retain most of the scarlet-red.

No. 12.

Brilliant green	0.05 per cent.
Eucalyptus oil	2 "
Olive oil	5 "
Adeps lanae hydrosus	4 "
Paraffinum molle	21 "
Paraffinum durum	67.95 "

No. 13. Flavine Wax.

Flavine	0.2 per cent.
Eucalyptus oil	2 "
Olive oil	5 "
Adeps lanae hydrosus	4 "
Paraffinum molle	21 "
Paraffinum durum	67.8 "

No. 14.

Dichloramine-T	0.2 per cent.
Eucalyptus oil	2 "
Olive oil	5 "
Paraffinum molle	25 "
Paraffinum durum	67.8 "

To make a Kilogram of Paraffin.

Take $\frac{1}{2}$ gram of brilliant green or 2 grams of scarlet-red or flavine, and 40 grams of lanoline, rub up the coloured material with the adeps lanae hydrosus until a highly-coloured smooth paste is obtained which contains no undisintegrated particles of the dye; using about half an ounce of water assists the solution of the dyes. Melt the paraffinum durum (678 grams), and add 210 grams of paraffinum molle and 50 c.cm. of olive oil. Let the temperature of the resulting mixture sink to at least 65° C., then stir in the previously prepared lanoline paste, stirring until thoroughly mixed. At about 55° C. add 20 c.cm. of eucalyptus oil, stir and allow to solidify.

The adeps lanae hydrosus is used as a suspending and diffusing agent. Smaller quantities do not satisfactorily take up the dyes. Larger quantities are undesirable, as they make the resultant wax less satisfactory to paint on. If the above directions are carefully followed, little of the dye falls out of suspension, although reheating the wax for use tends to make this occur. Unless small quantities of wax are melted at a time, it is advisable to stir the liquid before using. The scarlet-red forms the least satisfactory suspension, and requires stirring while using, but its therapeutic value has caused it to be persevered with.

To prepare dichloramine-T paraffin, dissolve the dichloramine-T in eucalyptus oil and add to the other ingredients at 55° C.

The dichloramine-T wax has proved an unsatisfactory wax from a practical point of view owing to the tendency to be brittle and adhere to the raw surface of the burn, instead of being easily removed in one piece, as is the case with the other preparations.

A CASE OF FULMINANT CEREBRO-SPINAL FEVER WITHOUT MENINGITIS.

BY

WILLIAM STCLAIR SYMMERS,

PROFESSOR OF PATHOLOGY, QUEEN'S UNIVERSITY, BELFAST.

THE case here reported is one of meningococcal infection, the course of which was so rapid (twenty hours) that the meningeal symptoms and signs remained undeveloped, whereas the outstanding symptoms (witness the laparotomy) pointed to some abdominal lesion, these symptoms being intense pain in the abdomen, rigidity of the recti, repeated vomiting, and diarrhoea. The absence of headache is to be remarked; the pain in the back was not associated with any naked-eye sign of spinal meningitis.

On September 16th, 1916, a boy aged 16, apparently in good health, went to his work as usual in one of the Belfast shipyards. Shortly after commencing work, about 7 a.m., he was seized with violent pain in the abdomen and back; he lay on the ground and vomited freely. He was sent to the Royal Victoria Hospital, arriving almost in collapse, cyanosed, and vomiting. There was now marked diarrhoea, some rigidity of the abdominal muscles, but no trace of headache; the temperature was 98° F. and the pulse 98. By evening the temperature was 100.2 F., and the pulse 130. There was still no headache, but increasing weakness and considerable cyanosis of face. He died twenty hours after the appearance of the first symptoms. Some hours after admission to hospital laparotomy had been performed by Mr. Holmes, without, however, throwing any light on the case.

At the post-mortem examination the points noted were as follows: numerous petechiae on the posterior aspect of the heart, an enlarged and much reddened thymus, enlarged mesenteric glands, some of which showed minute haemorrhages, marked enlargement of the solitary follicles in the lower ileum and colon, the bowel being hyperaemic; Peyer's patches were unchanged. The liver showed superficial yellowish patches scattered over the upper surface near the anterior border. The remaining thoracic and abdominal organs were normal.

The above appearances¹ were identical with those I have invariably seen at the autopsies in cases of cerebro-spinal fever in Belfast during the past seven years, and therefore, at this stage of the autopsy, this disease was suspected.

The brain and cord, however, on being removed, were found normal to the naked eye; there was not the slightest appearance of meningitis, unless some exceedingly faint turbidity of the scanty ventricular fluid could be so interpreted. This cerebro spinal fluid was small in amount, the brain and cord being somewhat drier than is normally the case. The few drops of fluid collected showed microscopically some finely granular debris, to which its faint turbidity was due; there were a few polymorphonuclear cells, but no inclusion of bacteria.

This fluid, when planted out on ascitic agar,² however, furnished very numerous colonies of the meningococcus in pure culture, the agar tubes being covered by scores of the typical colonies, consisting of the well-known Gram-negative cocci, which acted upon the various sugars in the manner characteristic of this organism—namely, acid production in maltose and dextrose, absence of acid on the others, including galactose.

CHLORINE WATER IN THE TREATMENT OF INFANTILE DIARRHOEA.

BY

S. ROSEBERY, M.B., CH.B. EDIN.

SENIOR MEDICAL OFFICER, SHOREDITCH INFIRMARY, LONDON.

THE use of chlorine water in the treatment of typhoid fever was advocated by Burney Yeo, and it occurred to me that it might be usefully applied to diarrhoeal conditions in children. The death-rate in these is high everywhere, and in Shoreditch and Hoxton the dangers are increased by the very unfavourable conditions under which most of these children are reared, and many of them were admitted to the Shoreditch Infirmary in a critical condition.

During recent months fifty-three cases have come under observation, varying to a considerable degree in severity,

In each case chlorine water in the following mixture was administered:

R. Aqua chlori	miv
Quin. sulph.	gr. ½
Salol	gr. iv
Mucilag. tragacanth.	q.s.
Aqua chloroformi	ad	5j

Dose: 5 ss to a child under six months, and proportionate doses in elder children.

This was given every six hours for the first twenty-four to thirty six hours, and then thrice a day until the stools were normal. In addition, 10 to 20 m, according to age, of the following mixture was administered twice a day:

Ol. ricini	3j
Ol. olivae	3j
Tinct. opii	mij

The opium, however small the dose, has a soothing effect upon the bowels, and helps to induce a much-needed rest, which is an important factor in treatment. Lavage of the bowel with normal saline was resorted to in many cases.

In the very severe cases, where the child was admitted in a collapsed state, with depression of the fontanelle, cold and dry skin, blue extremities, sunken and heavy eyes, and general flabby condition, a mustard bath was first ordered, to be followed immediately by injection of pituitrin $\frac{1}{4}$ c.cm., repeated two or three times at intervals of four hours. Then an inunction of warm olive oil was given to diminish loss of heat from the skin. Lavage of the bowel was practised two hours after the mustard bath. The diet in these cases varied according to the severity of the attack. In the milder cases albumin water and barley water were sufficient. In the more severe cases sherry whey was given first until the vomiting ceased.

The majority of cases recovered in four to five days, the very severe in ten to twelve days. In the latter it was often necessary to administer brandy in 10 to 20 m doses every two to four hours, as an additional check to collapse, and in such cases also during convalescence I have found thyroid, grain $\frac{1}{2}$ twice a day, useful in helping to accelerate recovery and increase weight, as recommended by Dr. J. Simpson of Edinburgh.

The essential difference between the treatment adopted and that which is in common use was the administration of chlorine water, and a comparison of the cases which received this with those treated without it has strongly disposed me in its favour. Time and facilities did not permit systematic bacteriological investigations, and no explanation of the action of chlorine is attempted, but clinical results were so striking as to justify a recommendation of this treatment.

Out of the fifty-three cases so treated there was one relapse and only one death, upon which unfortunately an autopsy was not allowed. As soon as the vomiting and diarrhoea had ceased, and the children considered well enough, they were placed on a milk mixture adapted to their age and condition, gradually increased in quantity and strength, and their weight regularly recorded. Before discharging the patients one or other of the infantile proprietary foods was given, suitable to their digestion, so that they became accustomed to an article of diet they were likely to receive at home.

A CASE OF CAESAREAN SECTION COMPLICATED BY RUPTURE OF THE UTERUS.

BY

MAJOR G. W. KILNER CROSLAND, D.S.O.,
HONORARY SURGEON, HUDDERSFIELD ROYAL INFIRMARY.

A SHORT account of an unusual complication in a case in which Caesarean section was twice done may be of interest.

Caesarean section was performed on Mrs. B., aged 26, by me in April, 1913, owing to contracted pelvis; she was delivered of a dead child, weighing 10½ lb.

She again became pregnant, and I saw her in consultation with Dr. Brown in June, 1917. I advised waiting until labour commenced and her admission then to the Royal Infirmary for a similar operation. Labour began on August 8th at 4.30 a.m. The pains were not severe; she was admitted to the infirmary at 3.30 p.m. She says that immediately after her admission she had three fairly strong pains, and that they then entirely ceased.

On admission the abdomen was rather tender, but the patient was not in pain; no uterine contractions could be felt; the

temperature was normal and the pulse 90. There were no signs of collapse, and she was quite cheerful. On vaginal examination the head was presenting, but had not entered the pelvis; the os was patulous, not much dilated, nor was the cervix drawn up.

The abdomen was prepared with iodine, and laparotomy was done at 7.30. On opening the peritoneum the uterus presented, the upper part being normal in appearance, but across the lower third there was a very large subperitoneal haematoma, which extended into both broad ligaments. It was difficult at first to make out the exact cause of this unusual complication, but on opening the uterus towards the fundus (where the wall was normal), as soon as the knife reached the edge of the haematoma it entered a large circular rent or gap in the middle line of the organ, about three inches in diameter, obviously a subperitoneal rupture of the uterus through the lower part of the scar left by the former operation. The living child and placenta were easily delivered.

The question of the best way of dealing with the condition then arose. Owing to the edges of the rent being very friable and much infiltrated with blood, it seemed to be impossible to close it in a satisfactory manner, and hysterectomy was considered. However, on account of the very large haematoma filling the pelvis, this was not thought feasible, and I decided to suture the incision in the uterus as best I could. This, of course, was easily done in the upper part, but when the rupture was reached great difficulty was experienced, and it was closed apparently not very effectively, owing to the infiltrated and lacerated edges. A large rubber tube was passed through the cervix and left there until morning to obviate any distension of the uterus with blood; an injection of pituitrin was given, and the patient, who had stood the operation well, removed to the ward.

After operation she never gave any cause for uneasiness, and made an uneventful convalescence.

An interesting point about the case is the freedom from signs of shock and collapse after such an injury to the uterus, with the subsequent effusion of so much blood. The pains also were never really very severe, nor was the os much dilated even at the time of operation. I was not at all satisfied that the closure of the uterine wound was effectual, and felt that if it had been possible hysterectomy would have been the better operation.

NOTE ON THE FATE OF HALAZONE IN THE ANIMAL BODY AND ON THE STABILITY OF TABLETS CONTAINING IT.

BY

E. K. DUNHAM, M.D.,

AND

H. D. DAKIN, D.Sc., F.R.S.

(Report to the Medical Research Committee.)

In a recent paper in this JOURNAL,¹ an account was given of the use of "halazone," *p*-sulphondichloraminobenzoic acid, for the sterilization of small quantities of infected water. As was previously stated, one of the great difficulties encountered in securing tablets of high germicidal potency for the sterilization of water has been occasioned by the lack of stability of the substances employed, when present in the small quantities required for tablets. Halazone appeared to offer distinct advantages in this respect over other substances hitherto made use of. Since our original communication we have had the opportunity of further testing the stability of our product and we have also determined its fate in the body when ingested.

The Fate of Halazone in the Animal Body.

Halazone even in large doses appears to be practically devoid of toxicity. We have fed rabbits for many weeks with doses of 100 to 200 mg. per day, without observable symptoms, and repeated doses of 500 mg. were also without effect. As the quantity needed for the sterilization of a quart of water is only 4 mg., the substance may be regarded as perfectly innocuous. The urine of rabbits which had received "halazone" given by stomach tube was collected and examined. As was to be expected, no unchanged substance was present and all active chlorine had disappeared. On acidifying the urine and extracting with ether, a crystalline acid was separated, which was purified by dissolving it in sodium carbonate and reprecipitating with hydrochloric acid. The substance decomposed at 280° C. and had all the properties of *p*-sulphonamidobenzoic acid. On analysis, the substance was found to contain 6.94 per cent. of nitrogen compared with a theoretical value of 6.96. The yield of pure acid recovered from the

urine was approximately 60 per cent. of the halazone fed, and as no other compound could be isolated, it is probable that halazone is quantitatively converted into *p*-sulphonamidobenzoic acid in the animal body, with the loss of two atoms of chlorine:

The Stability of Halazone Tablets.

In our first communication we emphasized the necessity of making tablets containing halazone with perfectly dry materials, using either dry sodium carbonate or borax with common salt. Our later experience has only served to confirm this conclusion, and also to indicate the superior keeping properties of the tablets containing dry borax or soda as compared with those containing sodium bicarbonate or salts containing water of crystallization. The difference is particularly marked at temperatures above 30° C.

The results of an extended series of experiments with halazone itself, and tablets containing it mixed with various salts, are now available. The tablets were made by ourselves from carefully dried material, and preserved in amber-coloured bottles. Their stability was estimated at three temperatures: (a) room temperature varying from 15° to 32° C., (b) 40° ± 2, (c) 50° ± 2. The amount of decomposition of the halazone was estimated by heating known quantities of the mixtures or tablets with potassium iodide in 50 per cent. acetic acid and titrating the liberated iodine with decinormal sodium thiosulphate. The deductions drawn from the experiments are as follows:

1. Halazone itself appears to be indefinitely stable at room temperature, while at 50° not more than 1 per cent. decomposition was noted in sixty days.

2. Halazone (5 per cent.) mixed with either dry borax or dry sodium chloride (95 per cent.) is stable at room temperature, but at 50° suffers about 20 per cent. decomposition in sixty days.

3. Tablets containing halazone (0.004 gram), dry borax (0.008 gram), and sodium chloride (0.088 gram) usually showed less than 2 per cent. and never more than 7 per cent. decomposition in 150 days at room temperature (15°–32°), and equally good results were obtained with similar tablets containing dry sodium carbonate (0.004 gram) in place of borax, while tablets containing sodium bicarbonate (0.004 gram) showed 7 per cent. decomposition. For practical purposes they may be regarded as stable at these temperatures.

At higher temperatures the rate of decomposition was most rapid with the bicarbonate tablets—namely, 76 per cent. decomposition in 115 days at 40°. The tablets with borax showed 35 to 48 per cent. decomposition in 115 days at 40° and 33 to 34 per cent. decomposition in 60 days at 50°. The tablets with sodium carbonate showed 48 per cent. decomposition in 95 days at 40° C.

The practical conclusions drawn from these results are as follows: Halazone tablets prepared from thoroughly dry materials, using sodium chloride with either borax or sodium carbonate and preserved in amber bottles, will maintain their germicidal efficiency at temperatures up to 32° almost unchanged for five months, and should be serviceable for considerably more than a year. Prolonged exposure to temperatures constantly maintained as high as 40° to 50° C. will reduce their efficiency by about one-half in three months.

MEDICAL, SURGICAL, OBSTETRICAL.

PRELIMINARY NOTE ON X-RAY DETECTION OF THE PRESENCE OF CLOTH IN WOUNDS.

THE result of some experiments which I have just made appear to me to justify the appearance of this note in advance of a detailed paper which I propose to write when I have finished the set. I am not aware that anything of the kind has hitherto been published.

Many wounds do not heal because of the presence in them of foreign bodies that are as pervious to x-rays as, or more so than, the tissues in which they are embedded; it may be that others may wish to avail themselves of a

proceeding likely, as it seems to me, to prove simple and effective in demonstrating their presence.

Having been lately asked to radiograph a leg for the purpose of detecting a piece of reed that was believed to have been in it for eighteen months, I failed, as I expected from my previous efforts in like work. With the aid, however, of bismuth emulsion injected into the sinus I was surprised and pleased to see in a stereo-radiogram—what was quite distinguishable *in situ*—a piece of reed about two inches long and one-eighth of an inch in diameter, and related to a sinus which branched.

This result immediately suggested the possibility of similarly demonstrating the presence of pieces of cloth in fresh wounds or old ones that refused to heal. I find that the texture of pieces of khaki cloth thrust into the interior of a lump of ox liver and similarly treated can be clearly distinguished.

It seems hardly credible that every radiographer who has injected refractory sinuses—there must be few that have not done so—has failed like myself hitherto to stumble on so simple a solution of this question.

Radiologist, Shanghai General Hospital.

Reports of Societies.

DISCUSSION ON SCOPOLAMINE-MORPHINE NARCOSIS IN CHILDBIRTH (PAINLESS CHILDBIRTH).

A MEETING of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine was held on December 6th, the President, Captain G. F. BLACKER, being in the chair. The discussion was opened by the reading of the papers forming the report of a committee appointed to investigate the effects of scopolamine-morphine narcosis. The Committee consisted of Dr. Fairbairn, Dr. T. G. Stevens, Dr. C. Hubert Roberts, Dr. Herbert Williamson, and Dr. Eardley Holland, but the last named was unable to take part owing to his absence on active service. The observations were carried out independently. A standard solution of scopolamine was employed, the initial dose being morphine gr. $\frac{1}{4}$, and scopolamine gr. $\frac{1}{150}$; subsequent doses consisted of scopolamine gr. $\frac{1}{150}$. The patient was isolated during labour, and, as far as possible, precautions were taken to avoid sensory impulses. The cases were selected by the officer in charge of the ward, and the patients were preferably to be primiparae in whom no complications were anticipated. Two charts were drawn up for use in the labour room, and at each injection observations were recorded, the results of which appear in the papers.

Report from St. Bartholomew's Hospital.

This report (read by Captain HERBERT WILLIAMSON) was on 20 cases only. Careful precautions were taken to avoid any disturbance to the patient.

Dosage.—The initial dose of morphine gr. $\frac{1}{4}$ and scopolamine gr. $\frac{1}{150}$ was given when the cervix was dilated sufficiently to admit a finger and, as a rule, when the pains were recurring regularly at intervals of not less than a quarter of an hour. One hour after the administration of the initial dose, $\frac{1}{150}$ gr. of scopolamine was given, and twenty minutes later an object with which the patient was not familiar was shown to her. From this point onwards the memory test alone was employed; it was considered a safe, but not an absolutely reliable guide, for there were instances in which apperception was present throughout, but amnesia was complete. It was the best guide to dosage, but demanded considerable experience and powers of close observation in the administrator. Its value was diminished by the necessity of arousing the patient each time it was applied. Two alternative tests had been suggested—Babinski's reflex and the pupillary pain reflex. These were tried in all cases, but were found of little value.

Effect on Uterine Contractions.—If the pains of the first stage were good before the administration was commenced little effect was produced; if they were weak, injection of the drugs sometimes led to their entire cessation. Experience at St. Bartholomew's Hospital confirmed that reached by Gauss—that in uterine inertia scopolamine-morphine narcosis should be avoided, for

under its influence the pains become weaker and sometimes cease entirely. In the absence of uterine inertia it was found that little effect was produced upon the strength, frequency, or duration of the contractions in the first stage. The second stage was markedly prolonged, especially amongst the primiparae. This was due to the lack of voluntary expulsive efforts on the part of the patient, and in three of the cases to weakening of the uterine contractions. The third stage was prolonged, but there was no severe *post-partum* haemorrhage. In three cases there was a temporary relaxation of the uterus four or five hours after delivery. A high percentage (45 per cent.) of the patients were delivered artificially. This was partly accounted for by the high proportion of abnormal labours, but Captain Williamson was of opinion that some of the patients in whom forceps were applied would have delivered themselves spontaneously had voluntary bearing-down efforts been present, and therefore, that scopolamine-morphine narcosis increased the number of instrumental deliveries.

Effect on General Condition.—There was no tendency to increase of maternal pulse rate, and in only one case were the respirations affected. Thirst was complained of by almost every patient. Nausea and vomiting were present in four cases. Distension of the bladder, with inability to pass urine, necessitating the use of the catheter, was present in six cases. Flushing of the face and dryness of the skin were marked, but never caused much distress. Restlessness was common during the stage of induction. Analgesia was marked in twelve of the patients, slight in five, and absent in three. No definite relation could be traced between analgesia and amnesia. Complete amnesia was attained in 11 cases, or 55 per cent., incomplete in 4 cases, or 20 per cent., and absent in 5 cases, or 25 per cent. In these the whole course of the labour was clearly remembered.

Effects upon the Child.—In sixteen cases the rate of the fetal heart was not affected, in four there was increased frequency, which might have been due to the labour itself. Nineteen of the children were born alive; one child was stillborn, but this was not to be attributed to the scopolamine-morphine narcosis. Of the nineteen born alive, eight were born in a condition of oligopnoea, undoubtedly due to the combined action of scopolamine and morphine. Most of the infants were born in this condition, and, although it appeared alarming, it was transient and need not cause anxiety. No treatment was required beyond covering up the child and keeping it warm. Of the nineteen children born alive all left the hospital well. In the majority there was no evidence that the scopolamine had produced any effect upon the child. There was no evidence that scopolamine was excreted in the milk, several cases having been examined.

The *puerperium* and period of recovery were not affected adversely by the injections. After long and trying labours the patients made a quicker recovery than those who had been delivered without it. Lactation was not affected unfavourably.

St. Thomas's Hospital.

Captain J. S. FAIRBAIRN read a paper giving his observations on 80 cases. The usual dosage was used except in a few of the later cases, when a slight modification was made, the second injection being $\frac{1}{300}$ gr. hyoscine instead of $\frac{1}{150}$. Cases of normal labour were preferred. Administration was begun when pains were regular, at about five minute intervals, and the os about two fingers, but it was difficult to be sure of the precise moment. Of the 80 cases 60 were primiparae and 20 multiparae. The number of injections varied from 1 to 19, the average being 6.5. In the primiparae the average was 7.2, and in the multiparae 5.5. The memory test proved quite useless. The behaviour of the patient between and during the pains and the notice she took of the prick of the hypodermic needle were found to be more useful, and had the great advantage of involving no additional disturbance of the patient. The method was to begin with hourly hyoscine injections, and when the drowsiness and absence of response to the pains, injections, or other manipulations indicated that the woman was fairly narcotized, to omit one or more of the hourly injections.

Amnesia was classified as "complete" when the patient remembered nothing from the time of the first injection;

as "partial" when she had no clear recollection of her labour but retained some impression of the final expulsive pains; as absent when she was able to recollect the events and progress of her labour. Complete amnesia was obtained in 36 cases—that is, 45 per cent.; partial amnesia was obtained in 26 cases, or 32.5 per cent.; amnesia was absent in 18 cases, or 22.5 per cent.

Analgesia was considered complete in all those cases in which complete amnesia was obtained, partial in those cases in which the patient appeared to obtain relief from the injections and was satisfied that she had had an easy labour, and absent in those cases in which she did not seem to have had any relief.

Complete analgesia was obtained in 36 cases = 45%	
Partial " " " 40 " = 50%	
No " " " 4 " = 5%	

No decided influence on the maternal pulse or respiration rate was observed. In 8 cases there was sufficient slowing of the pulse rate to be noteworthy; in only one case was quickening recorded.

Sleep between the pains was present in all but 3 cases, and in 27 there were periods in the labour when the pains did not rouse the patient. Mental confusion to some degree was present in most patients in whom narcosis was well marked. Restlessness to some degree was noted in 29 cases, and in many the result was good as far as amnesia was concerned. Thirst was present in 75 per cent. of the cases, vomiting in 20 per cent., and flushing of the face in nearly 90 per cent. Dilatation of the pupils was noted in 21 cases, or about 25 per cent. No dangerous effects on the mother were observed.

Effect on Labour Itself.—There was a fairly constant diminution in the strength and frequency of the contractions after the first injection, sometimes lasting an hour or two, after which the uterine contractions appeared to follow their normal development. Bearing-down efforts were present in 55, feeble in 10, and absent in 15 cases. There seemed to be a tendency to delay in the latter part of the second stage, shown by the increase in the number of forceps deliveries, which was more than three times the average ruling in the ward. The placenta was expelled spontaneously in 41 cases, and was expressed after expulsion from the uterus in 39 cases. Bleeding was stated to have been greater than normal in 9 cases, or 11.25 per cent. In 4 of these cases the bleeding was described as *post-partum* haemorrhage. The cases seemed to indicate a slight tendency to increased loss in the third stage, though readily controlled, but it was impossible to ascribe the haemorrhage to the narcotism alone. The condition of the patient after delivery was good throughout, and no case of shock or other dangerous symptom, except two cases of *post-partum* bleeding, was noticed. There were 3 cases of cardiac disease, in one of which the patient had been in the medical wards for several weeks owing to failure of compensation. In all these cases the partial narcosis had a beneficial effect on the patient. Out of 13 cases in which a general anaesthetic was given at the end of the second stage, complete amnesia occurred in all but one, or in 92.8 per cent. If the pain of expulsion brought the patient to consciousness the amnesic effect was lost. Probably all of the 26 cases classed as partial amnesia, and a proportion of those in which no amnesia was obtained, would have been classed as complete had the actual birth been conducted under a general anaesthetic, but given for this purpose. The second stage would no doubt have been prolonged and the number of forceps deliveries increased, but the percentage of complete amnesia would probably have been raised to 90 per cent.

Effect on the Child.—There were 3 cases of stillbirth, 2 of which were due to causes quite independent of the narcotism; in the third the fetal death was due to the delay in the aftercoming head. In 19 cases the child did not breathe or cry spontaneously at birth, but in 9 of these the delay was so trifling as to be scarcely worthy of notice. In 6 cases external stimulation, and in 3 a hot bath, were sufficient to start respiration at once. Besides these cases, in 16 there was blueness of the child, for the most part trifling in character and of short duration. Regarding pituitary extract given before birth as a contributory cause of difficulty in starting respirations, it was thought not to add appreciably to the danger to the child.

The General Lying-in Hospital, York Road, S.E.

Captain FAIRBAIRN read a report on 20 cases; 19 were primiparae, and 1 multipara; the number of injections varied from 1 to 17, the average being 6.8, in the primiparae only, 7.0. The methods, dosage, and drugs were as laid down by the Committee. The memory test was not of much assistance.

Amnesia was complete in 10 cases	= 50 %
" " partial " 7 "	= 35 %
" " absent " 3 "	= 15 %
Analgesia " complete " 10 "	= 50 %
" " partial " 8 "	= 40 %
" " absent " 2 "	= 10 %

Thus 10 per cent. of cases were failures; in 90 per cent. some relief was obtained; and in 50 per cent. complete amnesia and analgesia. No great effect was noticed in the mother. In 3 cases there was slight acceleration of the pulse towards the end of labour. No decided effect on respiration was found.

Some restlessness was present in half the cases observed. Flushing of the face and thirst were present at some time in nearly all cases. No dangerous effects on the mother were observed, and in all cases the convalescence was satisfactory.

Effect on Labour.—There was a marked delay in labour as the result of the narcosis, more especially in the absence of strong expulsive efforts at the end of the second stage, calling for instrumental delivery when the head was on the perineum. There was no evidence of delay or complication in the third stage, and no case of excessive haemorrhage. The condition of the mother after delivery was good throughout.

Effects on the Child.—There was spontaneous breathing in 65 per cent., breathing not spontaneous but easily started in 25 per cent., artificial respiration in 10 per cent. There were no stillbirths; but one infant, restored after artificial respiration for twenty minutes, died seven hours later. The child was immature and badly nourished.

Queen Charlotte's Hospital.

Dr. C. HUBERT ROBERTS read a report on 67 cases observed by himself and Dr. T. G. Stevens. The results were good. In 90 per cent. the pains of labour were diminished; complete amnesia was obtained in 46.2 per cent., partial in 44.7 per cent. Analgesia was complete in 32 cases, partial in 31. There were two failures.

Indications for commencing treatment were the character of the pains, which should be regular and strong. The size of the os could not be taken as a guide. The number of injections varied. Three patients had only one injection, whilst one had ten. In all cases but one the pains were good at the time of the first injection. Indications for repetition of the hyoscine injection seemed to be the patient's general condition and the frequency of the pains. In no case was a second dose of morphine given.

The memory test could not be relied on: observations on the corneal and plantar reflexes were of minor importance in drawing conclusions.

Considerable experience was required by the practitioner, and the same remark applied to nurses, who, if left in charge of such cases, should be carefully trained in the routine beforehand, as it was more than possible that dangerous results might supervene if the giving of morphine and hyoscine were left to inexperienced persons. Every case demanded the constant attendance of the doctor.

With regard to the general effects upon the patients, mental confusion, thirst, and restlessness, were observed in about half the cases, but no active delirium.

Effect on the Labour.—Labour did not seem so prolonged after giving the first injection. Any prolongation which was noted in their series occurred before the injections were given. Out of the 67 cases there were twelve forceps deliveries, but the indications were due to obstetric complications such as occipito-posterior positions, or large head, and not due to the effects of the drug on uterine contractions. The placenta was spontaneously expelled in 65 out of the 67 cases, there being evidence that uterine contraction and retraction was not interfered with. There were two cases in which there was haemorrhage in the third stage, one due to an adherent placenta, the other to a low-lying succenturiate placenta. These cases could not be laid to the door of the narcosis alone.

The puerperium in all cases was undisturbed, nor was involution retarded.

Effects on Infants.—In 53 out of 68 babies (one case of twins) breathing or crying was noted as spontaneous. In 13 cases the baby was described as blue, but in one instance only was there cause for alarm. Most of the blue babies at birth were limp, but soon recovered. Hot baths and artificial respiration were only required in the minority of cases. Violent resuscitative methods for such babies were to be deprecated. Three babies died; of these two were premature, and one died of bronchopneumonia on the sixth day. There were three cases of white asphyxia with forceps deliveries, due to delay from obstetric complications and not to the drugs used. A definite opinion on the effects of hyoscine and morphine on lactation could not be given owing to the short stay of patients in the hospital. Of the 64 living babies who left the hospital, 49 were breast-fed, and 34 had regained their birth weight during the first week.

City of London Lying-in Hospital.

Mr. GORDON LEY read a report on 135 cases observed by Dr. Comyns Berkeley and himself. Of the 135 cases reported, 128 were primiparae and 7 multiparae. The first injection was given with the cervix two fingers dilated and the pains strong and regular. The second dose was given three-quarters of an hour to one hour after the first, and the succeeding doses at hourly intervals. The number of injections varied from 1 to 53, with an average of 13.1. Morphine was repeated in $\frac{1}{4}$ grain dose in seven cases when consciousness was being gradually regained, and produced a satisfactory return to the desired state. The memory test was applied in all cases and was found generally unsatisfactory. Catheterization was, as a rule, necessary during labour.

Effect on Mother.—Complete amnesia was produced in 47.4 per cent. of the cases, partial amnesia in 45.2 per cent. Complete analgesia was produced in 8.2 per cent. Partial analgesia was present in 22.9 per cent., excluding in each case those patients in whom there was complete amnesia.

Thirst was present in 63 per cent. of the cases, nausea and vomiting in 24 per cent. Mental confusion was marked in 24 per cent., slight in 34 per cent. Restlessness was considerable in 25 per cent., slight in 17 per cent. Excitement was present in 35 per cent., and a small proportion of these were maniacal. Pulse and respiration were never affected. In 34 per cent. the pains appeared subnormal, and in one there was complete suppression. The interval between the pains was in all cases normal. Bearing-down efforts were, as a rule, subnormal. They were good in 44 per cent., fair in 3 per cent., slight in 40 per cent., very slight in 3 per cent., and absent in 10 per cent.

Labour.—There was prolongation of the second stage of labour. Compared with the average percentages of the hospital, the number of forceps cases was increased. perineal tears were greatly in excess (due to the difficulty of controlling the patient with the head on the perineum), and there was an increased failure of occipito-posterior positions to undergo spontaneous rotation, attributable to the lack of bearing-down efforts, which, combined with strong pains, are so important in the spontaneous rotation of these positions. The third stage was unaffected.

Effect on the Infant.—In some cases, especially when chloroform was given, there was a disinclination to breathe, associated with cyanosis and general limpness. Three children were stillborn. In one the pregnancy was only thirty-two weeks advanced. In the other two death was almost certainly due to intrauterine pressure resulting from the drainage away of the liquor amnii. Of the children born alive, the subsequent condition of 126 was satisfactory. Six died within the first twenty days of life, but in none could it be said definitely that the treatment played any part as a cause of death.

General Observations and Conclusions.—From the point of view of the practitioner, it must be remembered that the number of forceps cases is considerable, and these are relatively difficult owing to the fact that the diminished bearing-down efforts fail to force the head deeply into the outlet, or fail to rotate occipito-posterior positions, which therefore require manual rotation before extraction. The condition of the baby may cause grave anxiety to the inexperienced, and deaths are likely to be produced by too vigorous treatment. The constant attendance of the

doctor and the absolute necessity of having a nurse skilled in this line of treatment cannot be too forcibly impressed on patient and friends. The treatment requires considerable experience both of the method itself and of midwifery, and it appears probable that it should be withheld in all cases except those in which the capacity of the patient for bearing pain is greatly below the normal, and is evidenced early in labour.

DISCUSSION.

Dr. W. A. POTTS said that he had never met with nausea or vomiting. He thought the restlessness might be due to overdosage with hyoscine. He always gave morphine gr. $\frac{1}{4}$ to $\frac{1}{2}$, and hyoscine gr. $\frac{1}{32}$ to $\frac{1}{16}$, and for subsequent doses of hyoscine gr. $\frac{1}{32}$ at two-hourly or longer intervals. If the patient were not under at the third dose he gave a whiff of chloroform, and in this way could make a success of any case. He usually used chloroform at the end of labour, giving the last dose at some considerable interval before the child was born, so that at that time the patient was just coming from under its effects. It was essential that the patient be given water at intervals when the labour was prolonged, and it was advisable to let her come out from the influence of the drugs and have a meal, and then start the administration again. This diminished the tendency to uterine inertia. He had only had one case of *post-partum* haemorrhage, and that was probably due to slight capillary oozing from a small laceration of the cervix. He had not found an increased use of forceps necessary.

Dr. W. O. GREENWOOD said that out of a series of 240 cases he had only had two complete failures. He thought that his success depended upon frequent and rigid testing of the patient. The dose could be standardized, but the patients differed in their reaction to the drugs. He had used morphine gr. $\frac{1}{4}$ and scopolamine gr. $\frac{1}{16}$. Only highly nervous patients needed larger doses. He thought gr. $\frac{1}{32}$ too small a dose on the whole. He thought that if amnesia was perfect it was safe to say that there was some analgesia.

Dr. J. M. BRYDENE thought the method could be made an absolute and complete success from the patient's point of view. A little chloroform at the start was a great help. He had never given more than three injections. He had had no trouble with the babies. He had found the memory test unsatisfactory.

Dr. C. HUBERT ROBERTS considered that the method had given good results. Pain was diminished in practically 90 per cent. Administration should be begun when pains were regular and strong. The size of the os was no guide. Judgement was necessary with regard to the number of injections to be given. Repetition depended upon the condition of the patient and on the pains. Further observations were necessary to determine the value of the memory test. The corneal and plantar tests were of minor use. Training of physician and nurse was very necessary. Constant attendance on the part of the physician was needed. Prolongation of labour was not marked in their series. Warmth and quiet were all that were needed for the baby.

Lady BARRETT said that in a series of 50 hospital cases she had always given morphine gr. $\frac{1}{4}$. Patients had rarely failed to remember objects shown, but many had amnesia with regard to labour. She had had greater success by giving small amounts of chloroform at the end of labour, so that the last few pains were not remembered. There had been no case of *post-partum* haemorrhage. The only stillbirth was a small premature child.

Dr. COMYNS BERKELEY said that the memory test was useless. The only danger to the child was in trying to revive it. Strict supervision was necessary.

The PRESIDENT said that the method was by no means devoid of danger. Hyoscine was a dangerous drug owing to an idiosyncrasy towards it on the part of certain people, and once given hypodermically it could not be recalled. And on top of this dangerous drug chloroform was given as a general anaesthetic. The morbidity increased with the number of forceps cases. There was an increased morbidity of the mother, an increased mortality of the mother, and increased mortality of the baby.

Captain WILLIAMSON said the method was valuable in suitable and selected cases. It should be administered only after every precaution had been taken, and only by those who were competent to deal with any obstetrical emergency which might arise.

ATTEMPT TO PRODUCE CARCINOMA BY RADIUM.

At a meeting of the Pathological Section of the Royal Society of Medicine on December 4th, when Professor WILLIAM BULLOCK, F.R.S., president, was in the chair, Dr. W. S. LAZARUS-BARLOW described an attempt at the experimental production of carcinoma by means of radium. He showed microscope slides and a considerable number of lantern slides from rats and rabbits in which he had endeavoured to produce carcinoma experimentally. In the case of the rat minute tubes containing radium in amounts of the orders 10^{-8} to 10^{-1} mg. (calculated as element) were introduced beneath the skin. These experiments were undertaken on the basis of the facts that exposure to α rays caused squamous cell carcinoma of the hand, and that small quantities of radium had been demonstrated by him to be of frequent occurrence in carcinomatous tissue. In the case of the rabbit small gall stones obtained from the human subject and proved to be devoid of radium by alpha ray electroscopical analysis were artificially impregnated with radium and introduced into the gall bladders of the animals. These experiments were based on the fact that he had found a marked difference between the radium content of gall stones in man according as they were associated with cancer of the gall bladder or not, gall stones associated with cancer of the gall bladder containing relatively large quantities of radium, whereas gall stones associated with cancer of other parts, or unassociated with cancer, contained mere traces of radium or none could be detected. The experiments were commenced in 1912 and were not yet complete. He had not succeeded in producing in the animals the clinical condition known in man as cancer, but in the skin of rats he was able to produce, by means of suitable doses, an irregular, considerable overgrowth of squamous epithelium which sent processes into the corium, was frequently supplied with well-marked cell nests, and was indistinguishable histologically from a very early squamous cell carcinoma in man. This condition could be produced at will, but if the action of the radium persisted the newly formed cells came under its destructive influence, and if the radium were removed the skin condition receded with some rapidity, leaving merely a thin scar tissue devoid of hair and hair follicles. The gall bladder of rabbit experiments showed a more advanced condition, and a marked contrast obtained between the appearances of the gall bladders according as the gall stones introduced experimentally into them contained radium or not. Whether containing radium or not there was a great thickening of the connective tissue of the gall bladder, and this Dr. Lazarus-Barlow ascribed to the mere presence of the gall stones as a foreign body. But a fundamental difference obtained in the behaviour of the columnar epithelium lining the gall bladder according as the calculus which it contained was radium-free or impregnated with radium. If the calculus were radium-free the most that occurred was a slight polypoid overgrowth of the epithelium with an excessive formation of mucus; there was no tendency of the epithelium to invade the wall of the gall bladder. On the other hand, when the lining membrane of the gall bladder had been exposed to the action of a gall stone containing radium the epithelium showed changes indistinguishable from those occurring in columnar cell carcinoma in that there was an irregular growth of the epithelium which projected into the cavity of the gall bladder and invaded the thickened wall of the viscus in an irregular manner. As a consequence of the invasion, parts of the thickened gall bladder wall showed the presence of irregular tubules lined with columnar epithelium, grouped in irregular fashion through a less or greater thickness of the gall bladder wall, and usually preceded by a zone of lymphocytes. In one rabbit a metastatic focus exactly recalling the appearance of the gall bladder itself was found in a distant part of the liver. This was the sole metastasis found in the entire series of experiments, which involved 122 rats, 6 radium gall stone rabbits, and 3 control rabbits. Reference was made to experiments on the same lines carried out on mice at an early period of the research. In these animals the radium was not contained within tubes, and though introduced beneath the skin in the axillary region in the form of an insoluble sulphate or silicates, was found to disappear from the body within a few weeks. In

addition, it was not found possible to keep the animals alive for a prolonged period. Nevertheless, of 67 radium mice living six months after inoculation, 5 developed definite malignant tumours of the mamma (one animal bearing two primary tumours) and 7 other animals developed doubtful tumours (one papilloma and 6 nodular masses, chiefly in the neck, as large as peas, oscillating in size and finally disappearing). Thirteen control animals inoculated in the same way, but without radium and also living six months after inoculation, showed no tumour formation whatever.

Professor S. G. SHATTOCK, whilst fully recognizing the value of the results, and the prospect they opened up of further developments in experimentation upon the etiology of carcinoma, did not consider that the lesions could safely be regarded as more than precancerous. The downgrowth of the epidermis in the rat's skin in no case transgressed the limits of the corium; and on the removal of the radium the changes, instead of progressing, disappeared. In regard to the proliferative changes set up in the mucosa of the gall bladder by the action of radium introduced into gall stones, those seen in the bile ducts in coccidiosis of the rabbit's liver were quite as pronounced. The speaker held that for the production of carcinoma there still remained a second factor which needed discovery. The author's view that this consisted in a lessened resistance required scientific demonstration; nor was it logically the only other possibility, for there might be a second *extraneous* factor, such as the access of an ultramicroscopic virus. A further point against the change in the gall bladder being carcinomatous was the circumstance (as the author stated in answer) that the epithelial cells did not yield the proper Altmann granule test. Amongst the author's results there was one in which a metastasis had occurred in the liver; but here a second extraneous factor might have come into play, and the inflammatory proliferative process have been followed by the growth of a proper carcinoma.

EXPLOSIVE PHENOMENA IN GUNSHOT INJURIES.

At the same meeting of the Pathological Section Professor S. G. SHATTOCK, F.R.S., read a paper on explosive phenomena in gunshot injuries. He observed that, from the strictly pathological standpoint, the new factor introduced into gunshot injuries, as injuries, was the velocity of the penetrating body; they were otherwise confused and infected wounds like those produced by other foreign bodies, although their number and variety gave them special surgical features. Under the term "explosive effect" more than one thing was included: it was applied (1) to the increase of damage due to shattering of the bullet; (2) to the additional injury resulting from the comminution of a bone and the dispersal of its fragments; and (3) to the damage resulting from the high velocity of the missile. The last alone possessed any special pathological interest. It had been asserted (Professor Dr. K. Stargardt) that the British bullet was an expanding one, in consequence of the core being composed of aluminium at the point, and elsewhere of lead; that on striking (bone at least) the momentum of the lead carried this forwards over the harder aluminium, and so split the mantle. In order to test this the author had had recourse to the following experiment. The bullet was fired at a distance of 20 ft. through a sternum, into cotton waste, from which it was recovered without having struck any second object. The sternum was selected in order to obtain a direct hit. The bullet was found to have undergone no distortion whatever. Two sterna were then spliced together and shot through in the same way; the bullet, on recovery, was found quite undamaged. In solid organs the results of high velocity were best seen in the liver when perforated by rifle bullets at close range. The typical injury was a perforation accompanied with radial fissuring of wide extent. Even here the elimination of extraneous factors, such as obliquity of impact, or turning of the missile in transit, damage due to the introduction of clothing, could only be effected by experiment. In firing through suspended sheep livers at 20 ft. with a service rifle and pointed bullet, this was the form the injury took; the mechanical action of gas produced by explosion was eliminated by the distance. In analysing the physics of this result the wave of compressed air produced by the bullet (demonstrated by Professor Vernon Boys in instan-

taneous photographs) was wholly negligible. The speaker had found that if tense screens of tissue paper were shot through at 20 ft. with a service rifle, the hole was but little larger than the bullet; were the air wave of any moment the paper would obviously have been widely rent. Sir Victor Horsley, in commenting upon the cavitation produced in his experiments of firing into clay, attributed more importance to the spin of the bullet (centrifugal action) than to its forward movement. The speaker had carefully inspected all the plaster casts made from the clay in these experiments, and was unable to find the evidence of such rotation; the coarser ridges (representing shallow fissures in the clay) as well as the finer markings were longitudinal. The turn of the present British bullet was only in 10 in., yet explosive effects were observable in, for example, the sheep livers before referred to, where the thickness was only $1\frac{1}{2}$ in., which would reduce the rotation to less than a fifth. In only one specimen—in the collection on view in the Royal College of Surgeons—were the divergent fissures curved; here the bullet had traversed the body of the third lumbar vertebra first, and must have had some altogether exceptional twist imparted to it. The question was thus reduced to one of forward velocity. This was well shown in the liver by the fact that in perforations caused by shell fragments at low velocity a patulous tunnel alone resulted. The same difference was beautifully demonstrated in Horsley's casts, where the distal half was only of the calibre of the bullet, the explosive or dilating effect being limited to the proximal. In the case of the clay, the ready entrance of air from behind allowed of its cavitation; in the liver, where this was out of the question, the cavitation was represented by radial fissuring produced by the passage of the wave through an incompressible semisolid medium. In hollow organs the production of explosive effects depended upon their contents, other things being equal. Such effects from rifle bullets were not observed in the stomach or intestines by reason of the compressible air and gas which they contained; nor in the lung, for the same reason. The contusion, unattended with breach of surface, found, not rarely, in such organs, was possible from their extreme mobility and compressibility. The longitudinal wounds produced at times in the intestine by intact bullets were explained by the wall having been struck axially. In the case of the bladder, the contents of which were incompressible, explosive results were now and then encountered. In the Collection there was a bladder perforated by a rifle bullet which entered through the buttock without fracturing bone, and eventually escaped above the pubes; in the posterior wall of the bladder was an entry admitting the finger; the anterior wall (exit) was rent from top to bottom. The speaker had obtained similar explosive results by firing through ox bladders distended with water, a service rifle being used at 20 feet. The result was a simple hydrodynamic one, and due to the wave imparted to a mobile and incompressible fluid in a confined space. If the bladder was empty, or only lightly filled, the rending on the far side did not take place. In arteries and veins no hydrodynamic effect was observable, whether in unilateral or bilateral perforation. Its absence was possibly due to the indefinite continuity of fluid above and below the stricken spot and to the remarkable strength of both kinds of vessels. The speaker had been unable to produce either macroscopic or microscopic damage of the inner or middle coats of the human common iliac artery under the highest pressure that could be exerted with a dissecting-room syringe. In regard to the skeleton, the rigidity of the structure concerned was a complicating factor. If the upper part of the shaft of the tibia was compressed over a small area in a vice, however *slowly* the compression was made, extensive comminution and fissuring ensued far beyond the spot compressed. Nevertheless the same rule held: the greater the velocity of the missile the greater the damage.

The classical example of explosive effect was the well-known widespread comminution of the skull when bilaterally perforated by a rifle bullet at close range. The effects due to the gas of explosion had, of course, to be excluded. The results of suicidal shooting were thus liable to lead to false conclusions; a rifle fired into the mouth, with blank cartridge, would produce extensive comminution. This factor was, however, easily eliminated; the speaker had found, too, that sheep skulls with the

brain *in situ* underwent extensive comminution when shot through at 20 ft. with a service rifle, the foramen magnum being freely open. The result was not, properly speaking, hydraulic, but hydrodynamic—that is, it was not due to a generalized and equable internal pressure, but to the sudden impact of the incompressible cerebral substance against the interior of the cranium. A simple experiment, devised by the speaker, would emphasize this. A large, flat-sided “cocoa tin” was shot through in the empty state at 20 ft. with a service rifle; a circular entry and exit of about the diameter of the bullet resulted. A second tin was filled with water and shot through, the lid being removed; the entry was small and circular, the exit widely split, with large triangular flaps of the metal completely everted. The speaker had obtained pronounced explosive effects also in sheep skulls inverted and filled with water, the foramen magnum being freely open; if the skull was shot through in the empty condition, a circular entry and exit alone resulted.

Reviews.

DISEASES OF THE CHEST.

An important work on *Diseases of the Chest*¹ and the principles of their physical diagnosis has been written by three assistant professors of the University of Pennsylvania. The aim of the authors has been “to write a practical book on the physical diagnosis of the heart and lungs in health and disease”; the prognosis and treatment of disease are not considered. The text is divided into four parts. The first, by Professor NORRIS, contains a thorough and very excellent account of the physical examination of the lungs, special attention being given to the acoustics of the various diagnostic methods. Readers of this part of the volume will emerge from it with a vastly clarified appreciation of the physical basis underlying the methods of palpation, percussion, and auscultation as applied to the chest. An intelligent comprehension of the way in which both the normal and the abnormal physical signs in the thorax are generated is a thing hard for medical students to acquire, for the pages devoted to the subject in the textbooks at their disposal are habitually scanty and commonly discrepant. Yet without such an intelligent comprehension the student (and no less the medical practitioner he becomes) is necessarily at a great disadvantage when it comes to the interpretation of the results of his physical examination. For want of such an understanding he is apt to fall back on half-remembered dogmatic statements, things learnt by rote and not fully understood, with the result that the most astounding diagnoses are often attached to chest cases a little out of the common. We do not know of any book in which the exposition of this most important preliminary to the subject of physical diagnosis is so fully or so clearly treated.

Part II, also by Professor Norris, describes the examination of the circulatory system, with physical explanations of the way in which the normal and abnormal sounds that may be heard are produced. Here, as in other parts of the book, British readers will note that some of the terms with which they are familiar are not used in America, or are perhaps used in a sense differing from that to which they are accustomed. For example, the word “rhonchus,” often used on this side of the Atlantic to indicate musical or “dry” adventitious sounds produced in the air passages, does not seem to occur in the book. Again, Professor Norris applies the epithet “exocardial” to murmurs heard in connexion with the large arteries away from the heart, to the exclusion of murmurs produced outside the heart by the movements of the heart itself.

Part III contains an account of the diseases of the bronchi, lungs, pleura, and diaphragm. Part IV deals with the diseases of the pericardium, heart, and aorta. Both these parts are written by Professor LANDIS, and give adequate accounts of the subjects with which they are concerned. Great attention is paid to morbid

anatomy throughout the volume. The authors have endeavoured to teach as far as possible by means of illustrations, many of them photographs of frozen sections from the cadaver previously hardened in formalin. Indeed, the illustrations are one of the most striking features of the book, and form a most valuable and instructive series, well chosen, and well reproduced by the printer. The text is not free from misprints, and it is not too much to say that the authors are sadly to seek in Latin and Greek when it comes to the nomenclature of disease—a minor fault in view of the general excellence and novelty of their volume. The book may be warmly commended to the senior medical student, and it should be in the hands of all his medical instructors.

THE HUNGER COMPLEX.

MR. A. J. CARLSON'S monograph on *The Control of Hunger*² contains a summary of researches made in the Hull Physiological Laboratory of the University of Chicago. Six years ago Cannon and Washburn established by experiments the synchrony of hunger pangs with contractions of the empty stomach, and assumed a causal relation between these phenomena. The work done by Mr. Carlson and his colleagues not only confirms the results of Cannon and Washburn, but demonstrates a close parallelism between the degree of the stomach contractions and the intensity of the hunger sensation. Among the fifty subjects of their investigation one, Mr. F. V., had for twenty years had complete closure of the oesophagus and a gastric fistula permitting direct observation of the interior of the organ as well as the introduction of various appliances for experimental purposes. Stimulation of the gastric mucosa, it was found, produced hunger pangs only in so far as contractions of the organ resulted; in the absence of such contractions the results of the stimulation may be otherwise felt. Hunger is therefore of peripheral origin, and contains elements of kinesthetic sensation as well as of pain. It is analogous to muscular cramp, although differing in quality from that of other organs or the skeletal muscles. Hunger must not be confused with appetite, an independent, and, in a measure, antagonistic complex, for the secretion of gastric juice which may follow the thought, sight, or smell of food at the same time increases appetite and inhibits or diminishes the hunger pangs. Appetite is essentially a sense-reinforced memory of bygone pleasure in food.

The rhythm and strength of the hunger contractions are largely independent of extrinsic nerves. Section of the splanchnic nerves increases them by abolition of inhibitory control; section of the vagi renders the organ hypotonic, but so long as it is empty the alternate contractions and dilatations continue comparatively unchanged. The primary hunger centre is located by Mr. Carlson in the medulla, the sensory nuclei of the vagi. There are grounds for believing that, in common with other pains, that of hunger is also a thalamic function. Cortical processes are probably involved as well.

Some experiments on the effects of bitters commonly used in therapeutics proved that in ordinary doses they have no effect on the gastric tonus or hunger contractions. But it is for their effect upon appetite or secretion that such drugs are employed.

The author is to be congratulated on the production of a work embodying substantial additions to our physiological knowledge. The experimental grounds upon which his conclusions are based are clearly stated, and the book is written in a pleasant and readable style.

NOTES ON BOOKS.

DR. BEATRICE WEBB has written a most useful book of practical hints on the *Health of Working Girls*,³ for the use of welfare supervisors and social workers generally. Now that female labour is employed so very extensively in dangerous yet urgently necessary trades, the need for instruction in these matters is greater than ever. The author is fully competent to write on the subject from the medical point of view, and it appears that she has a first-hand knowledge of the working girl and her ways that

enables her to discourse with the authority of sympathetic comprehension. Her book is in every way excellent.

An address given by Sir THOMAS BARLOW last January to the Incorporated Association of Head Masters on the incidence of venereal disease and its relation to school life and school teaching has been issued as a pamphlet for the use of schoolmasters by the National Council for Combating Venereal Diseases.⁴ After a brief account of the prevalence of venereal diseases, Sir Thomas Barlow insists on the need for grasping the situation as a whole in any attempt to deal with sexual dangers during adolescence. His advice on the teaching of sex hygiene to schoolboys at various ages is based on the belief that elementary biological instruction, while valuable when not overdone, is second in importance to the moral appeal in the widest sense of that term. He is wisely suspicious of those elaborate schemes for teaching sex physiology by which enthusiasts hope to safeguard youth against sexual vice and disease.

Miss VERA WADDINGTON's *What Every Masseuse Should Know*⁵ is a handy little book for the pocket, which should prove very useful to beginners. The clear and accurate line drawings are excellently done, and show graphically the commoner grasps, grips, and movements, while the short descriptions are equally simple and intelligible.

Moxon, when complimented by one of his Guy's colleagues on his large classes, replied: "I don't suppose I give the men better bread-and-butter than you did, but I put a little mustard on the sandwich." In this latter respect Dr. Mercier resembles Moxon, and differs from ordinary medical writers. A review of the first edition of these finished sketches of character⁶ was published last February, and it is not surprising that the author has so soon been afforded the opportunity of revising his essays, and of replying to reviewers' criticisms of his use of the term "artistic temperament" for an unattractive set of qualities. This descriptive title has no classical or authoritative origin, and though Sir Ronald Ross, who suggests "the vain temperament" as more suitable, has the justification that vanity is a large ingredient, it is not all, for heartlessness is even more predominant. The main difference between the man with the artistic temperament and the artist is the latter's possession of that infinite capacity for taking pains which was Carlyle's definition of genius: but though it is an essential it is far from the whole of that rare property. There are many good and shrewd sayings in these pages which no one who enjoys the keen thrust of the author's pen should miss.

⁵ *What Every Masseuse Should Know*. By Vera Waddington. With prefatory notes by Sir Rickman Godlee, Bt., K.C.V.O., and Mrs. Annie E. Stewart, and an introduction by Laura M. Fairbairn. London: Methuen and Co., Ltd. 1917. (4½ × 5½, pp. 105; 47 illustrations. 2s. 6d.)

⁶ *Human Temperaments: Studies in Character*. By Charles Mercier, M.D., F.R.C.P. Second edition, revised. London: The Scientific Press, Ltd. 1917. (Post 8vo, pp. 91. 1s. 3d. net.)

THE SUPPLY OF INTOXICANT DRUGS TO MEMBERS OF H.M. FORCES.

In a penal case before the General Medical Council, which was reported in the SUPPLEMENT of December 8th, p. 114, the accused medical practitioner was found guilty of improper dealings with the narcotic drug heroin, and his name was struck off the *Medical Register*. With the general features of the case we do not propose to deal; the report supplies its own comment. The second count of the charge, however, needs a few words of explanation. This referred to the supply of heroin "for an officer and men, members of His Majesty's forces, contrary to Regulation 40 of the Defence of the Realm Regulations, and the Order of the Army Council dated May 11th, 1916." Regulation 40 makes it an offence, *inter alia*, to supply any intoxicant to a member of His Majesty's forces when on duty, or to supply him therewith, when not on duty, with the intent to make him drunk, or less capable of the efficient discharge of his duties. The expression "intoxicant" for the purpose of this regulation includes any intoxicating liquor, and any sedative, narcotic, or stimulant drug or preparation. Further, the Admiralty or Army Council is empowered by the regulation to prohibit or restrict by order the supply of any specified narcotic, or

stimulant drug, or preparation to members of His Majesty's forces. The Army Council accordingly issued on May 11th, 1916, an Order, reproduced below, with which medical practitioners should make themselves familiar:

No person shall sell or supply any article specified in the Schedule to this Order to or for any member of His Majesty's Forces unless ordered for him by a registered medical practitioner on a written prescription, dated and signed by the practitioner with his full name and qualifications, and marked with the words "Not to be repeated," and unless the person so selling or supplying shall mark the prescription with his name and address and the date on which it is dispensed.

Schedule.

Barbitone.	Codeine.
Benzamine lactate.	Diamorphine.
Benzamine hydrochloride.	Indian hemp.
Chloral hydrate.	Opium.
Coca.	Morphine.
Cocaine.	Sulphonal and its homologues.

All other salts, preparations, derivatives, or admixtures prepared therefrom or therewith.

It will be remembered that barbitone is diethyl barbituric acid, which was first introduced under the trade name "veronal." Benzamine lactate is commercially known as eucain lactate, and benzamine hydrochloride is the corresponding salt of eucain. Diamorphine is diacetylmorphine hydrochloride, unofficially known as "heroin." The homologues of sulphonal include trional and tetronal, and presumably also "reversed sulphonal," which is not strictly a homologue of sulphonal, but a metameride. Those who seek further guidance as to the artificial hypnotics which should be regarded as derivatives of barbitone or sulphonal may be referred to an article in the JOURNAL of April 19th, 1913, p. 835, on the chemical and pharmaceutical relationships of these compounds. The phrase "all other salts, derivatives, or admixtures" would probably be interpreted very widely in any case of doubt.

THE VOLUNTARY RATION FOR CHILDREN.

ON December 3rd the Ministry of Food issued to the press a scheme of voluntary rationing applicable to children. The table on the next page gives some details and deductions in extension of those published last week (p. 764.) The figures in brackets in the first column are the "man values" for the different ages adopted by the Royal Society (Food Committee) from the publications of Atwater and his collaborators. This scale takes the ages 14 to 15 and over 16 separately, and we have provisionally introduced 0.8 for the combined group. The proximate principles are computed from the Royal Society's analyses (beef being taken for meat, which somewhat underestimates the calorie value of the ration if pork or bacon is allowed for). The calories required are those based on the assumption of 3,500 for an adult's diet.

So far as young children are concerned, the deficit shown can be readily covered with milk, a pint daily (of energy value slightly exceeding 400 calories) being sufficient. At older ages the same difficulties will arise as in connexion with the diets of adults, potatoes being the only unrationed articles of high energy value. The evidence collected by Rubner¹ points to a very complete utilization of protein by growing animals and the desirability of special attention being devoted to the energetic basis of the dietary. He concluded that in all animals but man about 4,800 calories were needed for the production of a kilogram of body weight in the first stages of growth; in man the requirements were sixfold. The head of a family will be well advised to increase the children's sugar ration at the expense of that of the sedentary adults.

We may add that were a compulsory rationing system to be introduced the ratios that children's diets should bear to those of adults ought to receive much more attention. As Fendler, Stüber, and Burger have recently pointed out,² there are hopelessly discrepancies between the published standards of the chief writers. Thus for a child of 10, reckoning an adult man as 100, Engel reached 57.1, Rubner 49.2, Atwater 60, Zuntz 75, American

² Arch. f. Hygiene, lxxv, 1916, p. 1, etc.

Children's Rations.

Ages.		Per Head Weekly.								Grams per Head Daily.			Calories Daily.	Cereal Ratio.	Calories Required.	Deficit.		
		Bread.		Meat.		Cereals.		Fat.		Sugar.		Protein.					Fat.	Carbo- hydrates.
		lb.	oz.	lb.	oz.	lb.	oz.	lb.	oz.	lb.	oz.							
0-5 (0.4)	3	0	1	0	0	6	0	6	0	8	27.5	34.7	153.5	1,064	55.6	1,400	336
6-8 (0.5)	3	8	1	8	0	8	0	8	0	8	35.6	47.8	176.4	1,314	53.6	1,750	436
9-12 (0.6)	4	8	2	0	0	10	0	10	0	8	46.4	61.3	216.8	1,649	54.6	2,100	451
13-18 (0.8)	6	0	2	0	0	10	0	10	0	8	54.2	62.4	267.8	1,501	60.7	2,800	899

statistics of households 75, Danish statistics 50 for males and 40 for females. Some observations by Müller on Charlottenburg working-class children (quoted by Fendler, Stüber, and Berger, and relating to the year 1915 or earlier) give for children between 7 and 10 daily calories

varying between 1,585 and 2,118. As the heat values were determined directly with a bomb calorimeter they are not immediately comparable with the usual reductions, being too high. So far as they go, they do not conflict with the assumed standard.

MEDICINE IN INDIA.

A FRESH BLOW TO THE INDIAN MEDICAL SERVICE.

NEARLY ten years ago (in February, 1908) the Madras Government issued a circular interpreting existing orders to mean that all patients who visited a hospital supported from public funds were entitled to gratuitous medical advice irrespective of their circumstances, and nine years ago (in September, 1908) it issued an order stating that limitation of treatment at Government medical institutions to Government officials and to the poor was not in accordance with the intentions or orders of the Government of Madras. The matter was brought to the notice of the British Medical Association, which, in January, 1910, addressed a letter of protest to the Secretary of State, pointing out that the Order was contrary to the policy of the Secretary of State and the Government of India, which was to foster the independent medical profession in India. It also pointed out that if the hospitals provided by the Government of India were intended primarily for the treatment of the sick poor, the Order must lead to abuse, inasmuch as the grant of gratuitous relief, at a hospital, to patients in a position to pay for treatment diminished the amount of time and attention and the expenditure available for those who were suitable objects of charity; the fact that the hospitals were officered by paid Government officials and mainly supported by public funds did not alter their charitable object and scope. The matter received the prolonged consideration of the India Office and the Governor-General, for it was not until three years later (in March, 1913), and only after several further reminders, that the Association was informed by the India Office that the Governor-General in Council had promulgated a resolution making it known that the principle of discrimination between different classes of patients visiting public hospitals in respect of the medical advice afforded them was that towards which all provinces should work. The resolution went on to point out that—

The more important urban centres, where supervision is strongest and the supply of practitioners adequate, afford the best opportunity for an early move in this direction, and especially is this the case with reference to private wards in the larger hospitals. In fact, any patient who can afford to pay for separate accommodation should be charged a reasonable sum in addition for attendance and medicine, and care should be taken not to undersell private nursing homes and chemists' shops, or to compete with private medical men. In rural areas progress may be less rapid and it must be adapted to local conditions, but it is the wish of the Government of India that the object to be secured, namely, that persons should not be treated at the public expense who can afford to pay, should be consistently kept in view and action gradually taken as circumstances permit to attain this end.

The Madras Government ruminated this Order from the Government of India for three years, and then issued an Order (March 11th, 1916) containing rules to govern the levy of fees in State medical institutions in Madras city. With regard to out-patients, it laid down that well-to-do persons should not be given medical advice as out-patients except in cases of emergency, and that if they required the services of a medical officer they were at liberty to

make private arrangements with him for their treatment at his residence or at their own homes. Decision as to whether a person was to receive free medical advice was to be a matter for the medical officer in attendance, who might in any case of doubt require the production of satisfactory evidence.

The next section of the Order went on to lay down that poor in-patients should be treated and dieted free in general wards; other persons were to pay nursing and diet charges, and also a charge for medical advice or operation, except in the case of civil servants, but for a major operation or confinement persons whose incomes exceeded a certain amount were to be charged a fee subject to a maximum of 45 rupees. In-patients in special wards were to be charged according to a sliding scale in proportion to their income, for medical advice and minor operations, and for diet, with extra fees for a major operation or confinement. The medical officer in charge of the case, or if associated with a surgeon, jointly with the surgeon who performed the operation or attended the confinement, should determine the fee to be charged, subject to the prescribed maximum. All the charges, whether for nursing and diet, medical advice, operation or confinement, were to be credited in full to the Government.

This is the manner in which the Madras Government interprets the Order of the Governor-General in Council that "care should be taken not to undersell or to compete with private medical men." By opening its hospital to paying patients the Government directly encourages the paying patient to enter the wards of those hospitals which are established and maintained for the benefit of persons whose earnings would otherwise prevent them from obtaining suitable treatment or operation. So far from refraining from entering into the competition condemned by the Governor-General in Council the Madras Government proposes to make money out of the medical profession by appropriating from members of the medical profession the fees the patient has to pay for their skill.

The effect upon the Indian Medical Service must be as disastrous as upon the independent medical profession in India. The Government of India Act, 1915, which was a consolidating Act, re-enacted the clause which specifically reserved to barristers, physicians, surgeons, and chaplains in the way of their respective profession the right to accept fees. This is one of the inducements held out to young men to enter the Indian Medical Service, and, as has been said, it has been re-enacted and reaffirmed within the last two years; yet we find the Madras Government a few months later making a regulation which stultifies the Act of Parliament. If the maintenance of efficiency in the Indian Medical Service is essential to the interests of the people of India, and if this duty devolves on the Secretary of State and the Government of India, we would invite the Secretary of State for India during his visit to that country to look into the matter in consultation with the Governor-General. We would invite them to look at it from a broad and statesmanlike point of view, sweeping out of the way all petty jealousies and bureaucratic methods of provincial secretariats.

British Medical Journal.

SATURDAY, DECEMBER 15TH, 1917.

THE BIOLOGY OF WATERWORKS.

THERE is a pathology as well as a physiology of the making of food and beverages. In 1856 technical difficulties experienced in the distilling industries of Lille led Pasteur to study fermentation processes. Up to that time Liebig's view that the transformation of sugar into alcohol and carbonic acid was a purely chemical process, and not a vital phenomenon, held the field. In 1857 Pasteur furnished his first proofs that the process of fermentation is directly dependent upon the growth of living organisms. The fruits of these researches marked the beginning of the modern sciences of bacteriology and biochemistry. From the study of fermentation Pasteur passed to investigate the processes of putrefaction, and established that these, too, depend upon the activity of living organisms. In 1862 further fermentation studies satisfied him that the conversion of alcohol into acetic acid was the work of a living organism, and he made practical suggestions for improving the vinegar industry. He next studied side by side the physiology of normal grape fermentation and the pathology of wine diseases. By 1864 he had proved that morbid changes in wine coexisted with the presence and multiplication of microscopic vegetations. Between 1871 and 1876 Pasteur undertook similar investigations into the chemistry, physiology, and pathology of brewing, to the lasting advantage not merely of that industry, but of science.

The pathology of breadstuffs has lately attracted much general attention owing to the difficulty in baking uniformly good loaves from the variable mixture of wheaten flour with other cereals, which is known as Government regulation, or G.R. flour. It is apt to be forgotten that wheat alone of the cereals contains gluten—the colloidal protein substance indispensable to the porosity of bread. Bread baking is attended by risks of infection by low forms of vegetable life leading to such morbid states as "moulding" and "ropiness." The pathology of these changes is not well understood, but the production of rope—which has been the chief trouble with war bread—is favoured by hot weather, by the practice of damping loaves to keep up their weight, and possibly by the greater prevalence of the causative organism, *Bacillus mesentericus*, in the lower grades of imported grain. In passing it is curious to note that the primitive articles of diet and drink—bread, milk, beer, wine, and even water—are each prone to infections, which, from the viscid stringy appearances produced, are alike called "rope." Ropiness of ale was described as long ago as 1547.

The physiology and pathology of drinking water are illustrated in a recent publication by Mr. R. Kirkpatrick on *The Biology of Waterworks*, issued by the Museum of Natural History.¹ Sand filtration dates from 1826, when it was applied by Mr. James Simpson, Consulting Engineer to the Chelsea Water Company, to remove the gross contaminations of the Thames water then supplied to Londoners. It not only did this, but improved the taste and odour.

Simpson did not apparently realize, however, until ten or twelve years later that the slime or skin formed on the surface of the sand played an important part. It was ascertained in time that the filtered water contained a smaller proportion of soluble organic matter than the raw, a fact not to be explained on any theory of mechanical action, and, finally, that bacteria were stopped to the extent of 98 or 99 per cent. The film to which chiefly the filter owes its purifying efficiency begins to be visible in two or three days after the water is run on to a fresh sand bed. It consists of living growing organisms, the most numerous being various species of diatoms which are present at all times of the year. It may contain zoogloea colonies of various kinds of bacteria, and also frequently such representatives of the animal kingdom as amoebae and infusoria. In addition there is a certain amount of organic colloid matter and organic and inorganic particles. Diatoms are one-celled algae, the brownish protoplasm of which contains green chlorophyll. It secretes a siliceous skeleton or "frustule." The "frustule" has a gelatinous covering which sticks to the sand grains and gradually fills in the spaces between them, forming an effective mechanical strainer.

Green algae also grow abundantly in filter reservoirs, flourishing mostly in spring and summer. The most important are *Spirogyra*, which forms masses of unbranched filaments, and *Hydrodictyon*, or water-net, which forms a delicate green network, the meshes bounded by single cells over a quarter of an inch long. Both these green algae are useful, one reason being that they protect the diatom film. They may grow so copiously that when the filter bed is allowed to dry the layer they form can be rolled up, and hence is known as "carpet-weed."

But these mechanical actions are not the end of the story. Simpson noted that "an appearance resembling fermentation" was discernible in the water in contact with the sand. The diatoms and the green algae in the presence of sunlight, by virtue of the chlorophyll both contain, assimilate the carbon of the carbonic acid in the water and liberate oxygen. At this stage the water is troubled and of a brownish tint; if stirred a fine dust can be seen in suspension; this dust consists of diatoms. Bubbles rise to the surface, and Gizolme has recently shown that the gas they contain consists as to 55 or 60 per cent. of oxygen. In a few days the water clears, the diatoms falling, to form first patches and then a continuous layer on the sand. The activity of the algae varies with the quality of the light—that is, with the weather, the time of day, and the season of the year. Gizolme, working with Diénert, has shown that the greater this activity the fewer the *B. coli* in the filtered water.

Useful as are certain species of diatoms, there are others which may give water authorities much trouble. To the growth in certain reservoirs of *Astrionella*, so called because several individuals may be joined into a beautiful star-shaped group, and to another diatom, called *Tabellaria* from its flat square shape, was traced the oily flavour of the water supplied to the west of London in the winter of 1912-13. The taste, which was due to a light oil present in the protoplasm of these species, could be removed by adding a small quantity of potassium permanganate to the water; like other algae, they are very susceptible to traces of copper sulphate, one part in a million being sufficient to stop the growth of *Astrionella*. Certain blue-green algae, the lowest and simplest forms of the group, may also give trouble. They may appear in great numbers in lakes, causing the phenomena called "the breaking of the meres," when the

¹ London: Quaritch and Dulau and Co. 1917. (Price 1s.)

water acquires a green colour. The growth only lasts a few days, but the dead algae impart a foul smell rendering the water temporarily undrinkable. In the summer of 1907 certain London storage reservoirs became infected with an alga, *Oscillatoria*, so that the water looked as though it had been fouled with green paint.

An enemy with which water engineers have sometimes found it very difficult to deal is *Crenothrix*. It does not contain chlorophyll, and although presenting resemblances to the algae it is usually classed with the bacteria. It flourishes both in light and dark, but appears to be typically an organism of subsoil water. It thrives best in water containing iron and organic matter in solution. In mass, as when it forms a matting on stones or water weeds, it has a brown colour, due to the presence of iron in the ferric state in the filaments of which it is composed. It forms spores which are easily spread, and given the conditions favourable to it the nuisance may quickly become very serious; this happened at Cheltenham in 1896, as described by Dr. J. H. Garrett. Water badly infected with this organism becomes red owing to the iron, turbid on account of flakes, and putrid from the decaying protoplasm of the organism. Water pipes may become more or less blocked by a thick deposit containing the remains of the iron bacteria. Liverpool had great trouble from this cause a few years after it began to draw its supply from Lake Vyrnwy, seventy-seven miles away among the Welsh hills. At Oswestry, some eighteen miles from the lake, the water is passed through a sand filter. The amount of water delivered to the filter beds dwindled, and the interior of the pipes was found to be covered with a gelatinous layer containing *Crenothrix*. There was no trouble beyond Oswestry, which confirms the experience of other places, that efficient sand filtration is the best remedy. There are many other organisms, including sponges and polyzoa, which can flourish in reservoirs and water mains, and not only maintain themselves but afford a living to various plants and animals, including worms and small crustacea. The gemmules of sponges and the seed-like bodies (statoblasts) of sponges are arrested by the sand filter, which, as has been pointed out, owes its efficiency mainly to the surface film composed chiefly of diatoms, which do not pass through, but, owing to their gelatinous coating, stick to the sand grains.

The whole story of the sand filter for town water supplies is a curious example of how man may by accident hit upon a method of using a process of Nature to enable him to meet his needs when he becomes aggregated into large communities. It may be supposed that the process, or something like it, must have been at work in shallow lakes, and perhaps in rivers, since the beginning of things—a reflection which may afford the curious matter for speculation.

FOOD RESTRICTIONS FOR THE WELL-TO-DO.

THE discussion carried on recently in the columns of the daily press with respect to conditions prevailing in clubs and the more expensive hotels and restaurants raises issues which the medical practitioner must face both as a citizen and a man of science. So far as general policy is concerned the medical man cannot claim to speak with more confidence than any other educated citizen, but it is obvious to every one that long meals and many courses in restaurants, hotels,

clubs, or private houses, are altogether out of place to-day. They are not necessary for health, but rather inimical to it, especially during this period of mental and emotional stress. They are not expected by guests, and the conscience of many of them is offended thereby. We do not, however, propose to comment upon this aspect of the matter at length, but there are one or two points associated with the general problem which deserve brief reference.

The first is, that however drastically clubs and restaurants are rationed, the immediate additions to the stocks of food available for general consumption will be almost inappreciable. The establishments which have been most criticized in the press cater, generally speaking, for persons whose incomes are not less than £700 a year. The number of such persons cannot be ascertained with accuracy, but, to judge from the evidence submitted to the Select Committee on the Income Tax in 1906, it is doubtful whether there are more than 250,000 in a population of over 35 million "men." Obviously, therefore, merely reducing the personal consumption of food by the wealthy will hardly affect the general situation. It will be well to bear this fact in mind so as to discourage expectations which may have been excited by the rhetorical way in which the question tends to be treated. A more important consequence, apart from the obviously valuable psychological effect of a good example, is the possibility of utilizing the services of restaurant staffs in municipal and factory canteens. One of the qualities by which the expert cook is distinguished from the amateur is the skill with which the former can utilize material either wasted or rendered unappetizing by the latter. This is particularly true with respect to cooking potatoes; when the consumption of potatoes in large quantities is desired, the services of chefs as instructors to municipalities and upon the staffs of works canteens would be valuable.

Although we think nobody has objected to the rationing of clubs and restaurants in explicit terms, some apprehensions seem to exist respecting the requirements of brain workers. The train of thought appears to be as follows: The clients of expensive restaurants and clubs comprise a large proportion of brain workers; intellectual work is very exhausting, and therefore intellectual workers must have a specially nutritious diet. Few results in the physiology of nutrition are better established than that this argument is quite unsound. Atwater¹ made a careful series of measurements upon an individual when resting and when eight hours of the day were spent in severe mental work. The mean heat productions were 2,321 and 2,319 calories respectively per diem. Benedict and Carpenter² have repeated and confirmed this result, which has never been seriously challenged. Popular opinion to the contrary is due to a natural confusion between fatigue consequent upon muscular work and that produced by intellectual work. The physiological substratum of the latter is doubtless an increasing resistance to the passage of impulses within the central nervous system, the development of which in the case of lower level mechanisms and co-ordinated reflexes has been demonstrated by Sherrington in his classical researches. These changes are of very great importance and presumably associated with the degradation of energy to the form of heat, but the quantity of energy transformed is so small that, unlike the change due to muscular work, it does not appreciably affect the general level of

¹ *Experiments on the Metabolism of Matter and Energy in the Human Body*, Washington, 1905.

² *The Influence of Muscular and Mental Work on Metabolism*, Washington, 1909.

metabolism. No doubt those intellectual workers who are restless and irritable, continually pacing up and down their offices or running up and down stairs, will use more calories than when at rest. But it is the associated muscular activity, not the mental work, which is the cause of this. When it is remembered that not particularly brisk walking will raise the rate of metabolism to more than three times its resting value,³ the discouragement of visitors and the reduction in numbers of official conferences and meetings would seem to be a quite useful measure of food economy upon the part of sedentary workers. This at least is clear: that the medical man can authoritatively assure anxious brain workers that they do not need any preferential treatment in the matter of calories.

The practical conclusion which we draw is that the limitation and simplification of restaurant and hotel meals (which the military authorities have tried to enforce amongst officers), and also of private entertaining, should be taken in hand at once. Labour which might be better employed elsewhere would be set free, invidious comparisons between the lots of different social classes would be avoided, and there is no reason to expect that the output of brain work would be diminished in quantity or deteriorated in quality.

THE CREAM ORDER.

THE Cream Order, made by the Food Controller under the Defence of the Realm Regulations, came into force on December 8th and will continue in force until April 30th. The first clause deals with the use and sale of cream and forbids the use of cream except for butter-making or such other purpose as the Food Controller may authorize from time to time. The second clause makes certain exceptions; it provides that the first clause shall not affect "the consumption of fresh cream by children under the age of five years, patients in hospitals and other similar institutions, and invalids or other persons needing cream in the interests of their health." The person who sells or supplies the cream must in all such cases obtain certain documents which he must preserve and produce if required for the inspection of any person authorized in that behalf by the Food Controller or a Food Committee. The document in the case of a child must show its name, age, and address, the maximum amount to be supplied and the person to whom it is supplied; in the case of a hospital or institution, the name and address of the institution and the maximum amount to be supplied; in the case of an invalid or other person needing cream in the interests of health, the name and address of the person, the maximum amount to be supplied, the period of supply, "and the name and address of a duly qualified medical practitioner who has authorized such supply, and the date of such authority." Infringements of the Order are summary offences against the Defence of the Realm Regulations. The Cream Order resembles the Bread Order in that it in effect imposes a new duty on medical practitioners. The experience of the working of the Bread Order is sufficient to prove that the discharge of this duty may sometimes be difficult and irksome. No doubt, if exceptions were to be allowed on grounds of health, they could logically be granted only on the recommendation of a duly qualified medical practitioner, but it was soon found that the Bread Order had been drawn too wide. Too many people were claiming that on grounds of health they must eat white wheaten bread. It was, of course, alleged that the doctors were showing laxity in making recommendations, but those who made this allegation failed to observe that the Bread Order practically placed the doctor in the position of trying to prove a negative, of asserting that

a particular kind of bread which the individual thought would do him good, would not do him good. It was sought to remedy the defect in the Order by two means: The first was to subject all applications for special permits to review by the scientific adviser to the Food Controller, assisted in doubtful cases by a small advisory committee, consisting of Sir Thomas Barlow and Dr. Robert Hutchison; this was in effect, if not in form, to subject the doctor's recommendation to review. The second expedient was the issue of a memorandum¹ addressed to the medical profession setting out a number of disorders which in the judgement of the Food Controller and his advisers could not be ameliorated by substituting white bread for Regulation bread. The applications in the case of the Bread Order were required to be made direct by the invalid to the Ministry of Food, and the net result is that very few people are getting white wheaten bread because the Food Controller decides against nearly all applications on the grounds set out in the memorandum. The procedure under the Cream Order differs inasmuch as the application is to be made by the customer to the dairy direct, and it appears to be open to the dairyman to accede to a request if accompanied by a medical certificate, so that there is no reference to the Food Controller. This difference may, perhaps, be the result of his experience of the White Bread Order, but, if so, we cannot think that the experience has been profitably used. There is, as is well known, a great shortage of butter in many towns; the price is fixed, but, as the shops have little or none for sale, the majority of people cannot obtain it; it appears, however, that many dairymen have got cream and are prepared to supply it. We believe that the cream would be much better employed in butter-making and that the Food Controller would have been wiser to have faced the situation at once. He allows cream to be used for children under five without medical authorization, and we are disposed to think that this exception if not too wide would be at least quite wide enough. So far as we know, cream is seldom ordered by doctors for children, except in the case of bottle-fed infants in order to increase the proportion of fat when it is thought advisable that the milk should be considerably diluted with water. It is not, we believe, commonly ordered for children old enough to take a mixed diet; for them butter can take its place, and most children like bread-and-butter, though many prefer butter and bread. Judging from books of reference and from such inquiries as we have been able to make, we cannot find that cream is often recommended for adults, or for children under five, or for young persons. Though it may sometimes be a useful, it can seldom be a necessary, part of a sick-room dietary. Putting the matter shortly, we are inclined to think that the Food Controller is seeking to place upon the medical profession responsibility which really belongs to him. He has full official information with regard to the amount of cream available and likely to be available during the winter; he clearly considers that it ought to be used almost wholly for butter-making, yet he is giving up all the control he might and ought to exercise over the consumption of cream. We venture to urge that he should have the full courage of his opinion.

THE LABOUR PARTY AND THE MEDICAL PROFESSION.

THE draft constitution of the Labour Party, to be submitted to the conference at Nottingham in January, has now been published. The reason for its issue at the present time is primarily that the various proposals may be duly considered by existing organizations who will give instructions to their delegates, but the draft has a larger interest inasmuch as the scheme has for one of its objects to bring into the party membership "producers by brain" as well as "producers by hand." In that connexion, as we

³ See Zuntz and Schumburg, *Studien zu einer Physiologie des Menschen*, Berlin, 1901, p. 240, etc.

¹ BRITISH MEDICAL JOURNAL, October 20th, 1917, p. 524.

mentioned in our issue of November 10th, p. 626, there has been talk that the Labour candidates to be adopted for the next general election will include some members of the medical profession pledged to support the scheme for a State Medical Service. The draft constitution contemplates a reorganization of the Labour Party so as to avoid the loose representation of various political and social groupings that had made up the conferences hitherto. The intention is that the annual conference as heretofore shall settle the programme of the party, but the delegates will be sent under a new and more ordered plan. Moreover, before an issue is adopted as one of the "planks" of the programme it must obtain the support of two-thirds of the votes given on a card vote. Further, it appears that these definitions of issues are to be made broadly by the conference and that there is to be some reservation allowing room for the exercise of the judgement of the National Executive to adapt these outlines to the circumstances of a general election. This is because the conditions may vary after the decisions of the conference have been taken, and there is also provision to enable the Executive to call a special conference if time allows and if it thinks it desirable. Every Labour candidate will be required to adopt the programme, but will be left free to include in the terms of his address any other proposals not inconsistent therewith. For the new development the most important consideration naturally is the method whereby the conference delegates shall be elected, the more so because the conference in its turn will elect the National Executive according to the old practice. The arrangement shows a desire to go cautiously, which is not surprising, as the financial stability of the party depends upon the trade unions. Thus the elements to form the party conference are defined under four headings. Trade unions and other societies affiliated to the party may send one delegate for each 1,000 members whose fees are paid. Local labour parties will, generally speaking, be reckoned according to parliamentary constituencies, and the intention is that each local labour party shall send one delegate in respect of each parliamentary constituency, and have one vote in respect of that constituency. Central labour parties in divided boroughs will each receive one voting card, and an additional woman delegate may be appointed for each constituency in which the numbers of affiliated and individual women members exceed 500. Trades councils not embodied in the local labour party will be entitled to send one delegate. Members of the National Executive and duly sanctioned parliamentary candidates may attend the conference, but will have no right unless delegated to vote. The proportions of representation in the National Executive are also safeguarded. This Executive is to comprise, in addition to the treasurer, eleven representatives of the affiliated organizations, five representatives of the local labour parties, and four women; the election is to be by ballot vote on the card basis from three lists of nominations, according to the categories mentioned above. The "producers by brain," who may join the Labour Party if the draft scheme be adopted, will of course figure in the local labour parties. It is possible that if the accretions thus made are comparatively few they will be over-represented at the conference; on the other hand, if they enter in large numbers, it would appear that they will be under-represented, and that the constitution in course of time will require revision if it is to reflect the membership of the party. Another point of interest is the scheme for the adoption of parliamentary candidates. The local labour party, which in this sense may be taken presumably to comprehend all the elements already referred to, will need the sanction of the National Executive before it can bring forward a candidate in a constituency. Under the Representation of the People Bill election expenditure by a candidate is limited to 5d. per elector in boroughs and 7d. in counties. Labour Party candidates are to receive financial assistance for election

expenditure from the party funds on the basis of £1 per 1,000 electors when the constituency is a borough and £1 15s. per 1,000 electors when the constituency is a county division. It is assumed in this arrangement that the Representation of the People Bill will be passed into law and hence that the returning officer's expenses will fall upon the State. It is understood, therefore, that the financial assistance from the Labour Party funds will represent about the same amount for a party candidate as hitherto, with, of course, an obvious saving to the party, inasmuch as it will no longer have to find returning officer's fees. The constitution has been drawn up with immense care to make it comprehensive. The new voting basis will, it is expected, reduce the representation of the extremer Socialist bodies. On the other hand, the scheme obviously must bring the individual candidate very much under the control of the "machine."

THE CARE OF THE BLIND.

FOLLOWING the recommendation of the Departmental Committee on the Welfare of the Blind, Mr. Hayes Fisher, President of the Local Government Board, has appointed a committee to advise the Local Government Board on matters relating to the care and supervision of the blind, including any question which may be specially referred to them by the department. The members of this advisory committee number fifteen, with a departmental official as secretary. Several of the members are well known for their interest and experience in work for the welfare of the blind, and two are women. We expected to find two or three ophthalmic surgeons, but of the fifteen not one is a medical man. It seems incredible, for of all people who have information and experience as to the conditions producing and produced by blindness there is no one so well situated as the ophthalmic surgeon. His every-day object is the prevention or amelioration of blindness, and his work brings him into closer acquaintance than any other class with the needs and difficulties of the blind. If there be any "experts" on the "care of the blind" they are to be found amongst the ophthalmic surgeons. Yet the Local Government Board finds no room for them on its advisory committee. Unfortunately for the nation this curious attitude of indifference to competent advice is no new characteristic of the Local Government Board in relation to the affairs of the blind. Forty years ago the Ophthalmological Society, under the presidency of Jonathan Hutchinson, urged the Local Government Board to issue cards of warning against the dangers of ophthalmia neonatorum, but the then President of the Board refused, on the plea that cards would cost money. For years ophthalmic surgeons urged the Local Government Board to make ophthalmia neonatorum a notifiable disease, but the Board did nothing until local action forced its hands. Recently the British Medical Association urged the Board to institute better provision for the treatment of ophthalmia neonatorum in London; it has got fair words, but no deeds as yet. Mr. Hayes Fisher's excuse is that his new committee is for administrative purposes only, and that if and when he desires expert advice he has no doubt of securing it on application as heretofore. No doubt. There is no ophthalmic surgeon so lacking in bowels of mercy as to refuse help for the blind, no matter who may ask. But Mr. Hayes Fisher fails to appreciate the fact that advice must be conditioned by circumstances. To get the best advice of practical application, his medical advisers must know all the circumstances of the question, and they can only do that if they have the opportunity of becoming acquainted with intended developments of the administrative side of the problem by sitting on the committee appointed to deal with it. Mr. Hayes Fisher has got his new "administrative" advisory committee, but it lacks that motive power in preventive medicine which can only come from the medical profession. He has got the gear wheels of a watch, but no mainspring; his gear will go so long as

some finger pushes the wheels and the dust and inertia of his department do not clog it into rigidity. The Local Government Board professes to be unable to understand why it is regarded with suspicion not without a trace of contempt by so many classes of the community. Such action as this in a matter so closely connected with medicine may help to explain the strong objection taken by many experienced members of the medical profession to the suggested conversion of the Local Government Board into the much-desired Ministry of Health.

MILITARY ORTHOPAEDIC CENTRES.

THE Military Orthopaedic Hospital at Shepherd's Bush is generally considered to be the head quarters of military orthopaedics in the British Isles, and a pamphlet¹ describing its organization will be read with interest. It is established in several large blocks, formerly the Hammersmith Infirmary and Workhouse, but the accommodation has been considerably increased, so that it now provides 1,100 beds. In addition, four houses in the neighbourhood have been taken over for convalescent patients. As an auxiliary hospital, it has the Manor House Hospital, Golder's Green, opened on September 29th last, and St. Katherine's Lodge, Regent's Park, maintained entirely by the American Red Cross, acting on behalf of the donors, Mr. and Mrs. Salomon, was opened on October 4th as an annexe for officers. The various forms of treatment carried on at the Shepherd's Bush Hospital are fully described. At present there is a large operating theatre and a small room used as a septic theatre. The number of operations performed is, however, so large—from sixty to seventy a week—that the need of another theatre has been felt, and, at the request of H.M. King Manuel, the Joint War Committee of the British Red Cross Society and the Order of St. John has agreed to provide the requisite money, and a new theatre with accessory rooms is now in course of erection. The electro-therapeutic department, massage department, and hydrotherapeutic department are described and illustrated by photographs, as is also a fine new gymnasium presented by King Manuel and equipped with modern appliances for remedial gymnastics. There is also a plaster department, an x-ray department, a museum, and, finally, a set of curative workshops, which are among the most interesting developments of military orthopaedics. The plans have been carried out under the general direction of Colonel Sir Robert Jones, who is arranging that curative manual treatment shall be introduced into every orthopaedic centre, so that patients can be provided with some light and congenial occupation. The first step at Shepherd's Bush was to ascertain every man's pre-war occupation, and each man is, as far as possible, employed at his old trade, with special regard, of course, to his particular injury. The last point is the fundamental part of the scheme, and every effort has been made to prescribe work which shall have a direct beneficial effect upon the man's injured limb; for instance, a man suffering from adhesions or weak musculature of the foot is put to work at a treadle fretsaw, or sewing machine; in this way results are obtained by natural movement which previously had only been reached by such artificial and uninteresting methods as pedalling a dummy bicycle. The pamphlet contains a set of appendices, giving details and prices of the equipment of the several departments, which will be of service to those who have to organize orthopaedic centres elsewhere. Major Walter Hill, R.A.M.C., the officer in charge, states in a short preface that the pamphlet has been compiled by Private D. H. Eade of the London Regiment, a patient in the hospital, the details of the treatment in the various departments having been supplied by Captain W. R. Bristow, R.A.M.C.,

for the electrical department, Dr. Mennell for the massage department, Dr. Sonntag for the hydrotherapeutic department, and Corporal J. Wilde, R.A.M.C., for the plaster department. There is an introductory note by King Manuel, which may be summed up in the statement that as the Shepherd's Bush Hospital was the mother of military orthopaedic hospitals in this country, so now it aspires to be their model. The success which has been attained is largely due to the great interest King Manuel has taken in all the work, but especially in that of the curative workshops.

THE JERUSALEM MISSION HOSPITAL.

GENERAL ALLENBY'S achievement in capturing Jerusalem from the Turks, which marks an epoch in the history of Christendom, reminds us that for nearly a hundred years a medical mission has been at work in the city of Zion, awaiting patiently the setting of the Moslem crescent. The work of the Jerusalem Medical Mission, belonging to the London Society for Promoting Christianity amongst the Jews, was begun in a small way in 1824 by Dr. Edward Dalton, who died two years later, but the real founder of the mission was Dr. E. Macgowan, a man of remarkable character, through whose endeavours the hospital was opened in 1844. He was followed by Dr. T. Chaplin, who laboured for twenty-five years, and was succeeded by Dr. d'Erf Wheeler, who was head of the mission for a like period. Dr. Wheeler did much to develop the work of the hospital, and obtained new buildings in 1897. In 1893 he was joined by Dr. E. W. G. Masterman, who succeeded him as medical superintendent eight years ago. In recent years a new dispensary and children's wards have been added. Of the multifarious diseases of Palestine which are treated in the mission hospital malaria overshadows all others. All forms of tuberculosis are painfully common, trachoma is rife, and intestinal worms are universal among the poorer classes. The infant death-rate is very high. There is no isolation of the infectious, no enforced vaccination, and no real sanitary system at all. Unlike most medical missions in the East, the medical cases are more numerous than the surgical. Beyond the treatment of the Jewish sick poor the medical staff have the professional care of a considerable mission community in a climate often very trying to Europeans.

GERMAN PSYCHOLOGY UNDER AERIAL BOMBARDMENT.

THE mixture of self-consciousness and pomposity with which a German professor will discuss a subject about which he knows no more than the rest of the world may be very irritating or mildly amusing according to the mood of the reader. Professor Hoche has recently confided to the *Medizinische Klinik* of Berlin the effects of aeroplane attacks on Freiburg in Baden observed by himself and other physicians. Freiburg is a town of 80,000 inhabitants and the first attacks, made with comparatively small bombs, left no strong impressions; but when, from April onwards, larger bombs were used, the nerves of Freiburg suffered more, partly because the safety sought in cellars proved to a certain extent illusory. Hoche states that the effect of a bombardment on the minds of the inhabitants of Freiburg was directly proportional to the loudness of the explosions, and in this connexion remarks that some persons dread thunder more than lightning. The calculation that the chances of being wounded were infinitely smaller for the individual at Freiburg than for the soldier at the front did not prevent an artillery officer who had lived through the battles of the Somme from finding the explosions in Freiburg far more terrifying. This, Hoche thinks, must be due in part to the enforced passivity of the bombarded; in the case of a man who could take an active part in defence the mental strain was relieved. Hence, the greatest sufferers were the most helpless, the bedridden, and patients recently operated on; patients with fever were indifferent. Bombs released at a height of 3,000 to

¹ *Organization and Methods of the Military Orthopaedic Hospital, Shepherd's Bush, London, W. 12.* 1917. London: St. Clement's Press, Ltd. 2s.

4,000 metres travel, Hoche calculates, at an average velocity of only 150 metres a second, but the whistling sound their passage made travelled at the rate of 333 metres, so that the explosion was preceded by a period of tension lasting several seconds. This anticipatory tension had a most injurious effect on the nerves, the most common expressions of fear being chattering of the teeth, pallor, more or less mechanical praying, hysterical laughter, diarrhoea, rapid excretion of urine, and great thirst. The April bombardments did not provide the lunatic asylums with a single new case, a fact which Hoche, who is professor of psychiatry in the University of Freiburg, considers emphasizes the view that the development of insanity is remarkably independent of external factors. The inmates of the Freiburg asylum were little disturbed, and some of them even regarded a bombardment as an agreeable entertainment. Among the sane, insomnia was a common phenomenon, and in some cases, we are told, necessitated change of residence. Cardiac symptoms were often prominent, not in the subjects of organic disease, but in cases of nervous origin, notably in the "thyreo-toxic" group. Increased excretion of sugar, amenorrhoea, vomiting, and attacks of asthma, giddiness, and general weakness were also observed. Persons buried for seconds or hours in the ruins of houses might completely lose count of the lapse of time. They could recall visual but not auditory impressions; they could remember, for instance, seeing the walls falling, but not the sound of the explosion.

PREPARATION OF THE SKIN FOR ANTITETANIC INJECTION.

We hear that a number of cases of abscess have been reported lately following on the subcutaneous injection of antitoxin, and it seems possible that some of them have been due to the insufficiency of the measures taken for the sterilization of the skin. At present tincture of iodine is the favourite antiseptic for this purpose, but the mere painting of the skin with iodine is not sufficient. Dr. Kenneth Goadby, a member of the War Office Committee for the Study of Tetanus, has stated that "the method which has proved to be the most advantageous for the preparation of skin for injection of vaccines and anti-tetanus serum at the Royal Herbert Hospital has been the application of tincture of iodine to the skin surface. A pad soaked in the solution is allowed to remain upon the spot at which the injection is to be performed for five minutes, and immediately after the injection is performed a further application of iodine is made. If ether soap is used for cleansing the skin it should contain 1 in 1,000 mercury biniodide, the skin being thoroughly rubbed for at least a minute, so that the external epithelium is removed and with it any lurking organisms. The iodine method is, however, more simple, and allows of a number of men being prepared for inoculation in rotation. The adoption of this method has quite eliminated the local manifestations of sepsis which occurred in a limited number of cases."

A REUTER'S telegram from Christiania, dated December 10th, states that the Nobel Peace Prize for 1917 has been awarded by the Nobel Committee of the Norwegian Storting to the International Red Cross Committee of Geneva. It was unanimously decided to add the Peace Prize for 1916, which was last year reserved, to the special fund of the Committee. The work done by the Swiss Red Cross from the earliest stage of the war has been beyond all praise, and there is no relaxation in its efforts. It has, we may remember, helped in the distribution of bread to prisoners in Germany, and has given every assistance and a cordial welcome to soldiers who, under international agreement, have been permitted to leave their places of imprisonment for internment under friendly conditions in Switzerland.

Medical Notes in Parliament.

Insurance Amendment Bill.—Few amendments were made in the amending Insurance Bill in its passage through Grand Committee, and these were of a minor character. A subsection was added to Section 41 to provide for the payment of travelling expenses for medical practitioners who have to undertake administrative work. The new section is as follows:

Any travelling expenses incurred by members of any local committee elected under subsection (1) of section thirty-three of the National Insurance Act, 1913, or of any committee elected by medical practitioners under section thirty-two of the said Act in attending meetings of the committee or of any sub-committee thereof, and any expenses incurred by any such members on account of subsistence whilst so attending shall be deemed to be administrative expenses of the committee within the meaning of subsection (2) of the said section thirty-three.

It will be remembered that Clause 32 of the bill contains a provision to enable the Insurance Commissioners to remove the name of any medical practitioner from all or any of the panel lists, and to reinstate. Under the old Act the liability to removal affected one panel only. In Grand Committee the bill was amended so that the new general provision applies not only to medical practitioners, but to "any person, firm, or body corporate, undertaking the supply of drugs, medicines and appliances."

The Proposed Ministry of Health.—Mr. Anderson asked the President of the Local Government Board whether he was in a position to make a statement regarding the proposed Ministry of Health; whether it was intended to introduce legislation, and if so, when; whether an agreed scheme had yet been reached; and what steps were being taken to this end. Mr. Walsh (Parliamentary Secretary to the Local Government Board) said he was sorry he could not give any further reply than those which had already been given on the subject. Sir William Collins: Is there any prospect of a great scheme being arrived at unless and until a further consultation of the various interests of the parties has taken place? Mr. Walsh: That is a matter of policy on which I am unable to speak.

The Army Medical Corps and Hospital Inspections.—Major David Davies asked Mr. Macpherson whether he was aware that when the Territorial Medical Force was founded in 1908, definite specific promises were made concerning such questions as rank, pay, and the character of the work to be undertaken in war to medical men who were invited to join the force; and that, by one of these promises, it was guaranteed that the duties of *à la suite* officers of the Royal Army Medical Corps, Territorial Force, would be in time of war identical with those which they performed in civil life. Major Davies asked, further, whether such officers were now compelled to inspect hospitals already inspected by direct representatives of the War Office, to sit upon medical boards, and to perform other administrative duties which they regarded as a violation of the pledge under which they originally joined the Territorial Medical Force. Mr. Macpherson, in reply to the first part of the question, referred Major Davies to an answer given on November 6th to Mr. Alden (BRITISH MEDICAL JOURNAL, November 10th, p. 628). On the second part of the question, Mr. Macpherson said he was not aware that any of these officers were called upon to inspect hospitals administratively, although they might be required to inspect patients. Sitting on medical boards was purely medical work.

Medical Practitioners in Military Hospitals.—In reply to Mr. Lynd, Mr. Macpherson said that the services of medical officers of the army of the United States were being made use of in the military hospitals at home and abroad, not only to release medical practitioners required for the army, but in order to afford these officers opportunities of acquiring practical military experience with troops under service conditions.

Week-end Leave for Military Medical Men.—Mr. Clough asked whether Army Council Instructions No. A.C.1 1564 of 1917 for grants of leave from Friday to Tuesday on the authority of local commanding officers applied also to officers of the Royal Army Medical Corps; and, if so, would Mr. Macpherson, by circular or otherwise, make this known to all commands. Mr. Macpherson replied that the instructions referred to applied to all officers, including those of the Royal Army Medical Corps, and as these were issued to all concerned no supplementary circular was considered necessary.

The Training of Discharged Soldiers.—Mr. T. Richardson asked what was the number of soldiers discharged from the army in England, Wales, Scotland, and Ireland who were being trained in institutions set going by private philanthropists, such as the Lord Roberts Workshops, St. Dunstan's, the Cowen Home, etc., and how many were being trained in institutions set up by Local Pensions Committees and paid for out of the Imperial Fund. Sir A. Griffith-Boscawen replied that approximately 2,400 discharged soldiers were receiving training, including about 900 at the institutions referred to. Fresh schemes of training were being organized throughout the country, and trade advisory committees were being set up in connexion with the Ministry of Labour to regulate the conditions of training employment, and rates of remuneration in various trades.

THE WAR.

A SAND SLEDGE.

MAJOR W. CAMERON MACAULAY, B.A., M.B.Lond., R.A.M.C.(T.), writes:

A simple sledge for the conveyance of sick and wounded in sandy countries can be improvised easily and quickly from a single sheet of corrugated iron.

An ordinary sheet of corrugated iron, 7 ft. long, is hammered out flat. The sides and one end (back) are bent up at right angles so as to form a tray with sides $3\frac{1}{2}$ in. high. The other end (front) should be turned up in a forward and upward direction to form a quadrant instead of a right angle. This gives the sledge the necessary "lift."

The front is greatly strengthened by being turned up over a five gallon oil drum (Fig. 1). Made according to the foregoing dimensions, the tray will just take an ambulance stretcher, the front handles being at either side of the oil drum and the back handles projecting over the back.

Half-way across the front, at a point just below the horizontal diameter of the drum, a screw hook is passed backwards through the corrugated iron, the drum and a bar of wood $1\frac{1}{2}$ to 2 in. thick and the length of the drum inside. To this hook a few links of chain and a swingle-tree are attached for mule or camel draught (Fig. 1).

In order to allow of riveting, etc., on the inside of the drum, a door should be cut. The upper posterior quadrant of the drum cylinder throughout nearly its whole length is removed and by means of tibbin-band

FIG. 2.

flanges and improvised hinges can be replaced. The drum then forms a handy locker for dressings, water bottle, etc. (Fig. 2).

A hood for protecting the patient from sun and dust can be improvised out of sail-cloth, supported by hoops made of tibbin-bands which may be greatly strengthened by slightly arching or bending the width throughout the whole length except where an angle is required. The ends of these loops are further bent round laterally to form a

tube. These latter fit into similar tubes, slightly larger in bore, which are riveted to the upstanding sides of the sledge (Fig. 3). Canvas or stout linen 3 ft. wide is sufficient to cover either the front or rear half of the stretcher and the hoop slots should be so arranged on the sledge as to render either position possible. The end of the hood through which the patient's body passes should be divided down the centre in its lower half and the slit so formed fastened by tapes as required so as to conform to the bulk of the patient.

The whole of the work can be done by a handy man with very few ordinary tools. Rivets can be made from French nails of varying sizes according to requirement, and cut short. The cut ends are burred over

FIG. 1.—Showing side of hood partly rolled up.

with a riveting hammer. If properly made these rivets are very strong.

While not competing with the claims of any more elaborate sledge at present in use, this improvised sledge has some obvious advantages.

These are:

1. It is *simple and practicable*.

An ordinary handy man, without special technical skill and with a few rough tools, can "knock up" a sledge in a day from material generally to be obtained locally.

2. It is *economical* in men, animals, and material. One driver and one animal are sufficient per patient. A sand cart requires two drivers and four animals for two lying patients.

3. It is *comfortable*—by far the most comfortable "ride" of any means of transport at present available in the desert. It is absolutely steady and there is no jarring and very little bumping. It is essentially suitable for severe cases—such as abdominal, spinal, chest, and thigh-fracture cases—

where jarring and bumping are to be minimized. In a bad spinal case a mattress could be substituted for the stretcher.

4. It is *durable*. The sledge bottom does not readily wear out on moving sand, nor does it become heated. The sledge is not intended for prolonged use on hard roads or fixed ground, on which it would doubtless become heated and in time wear through.

FIG. 3.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

MAJOR G. R. C. CLARKE, R.A.M.C.

Major G. R. C. Clarke, Australian Army Medical Corps, was reported killed in action, in the casualty list published on December 8th.

CAPTAIN J. O'S. BEVERIDGE, R.A.M.C.

Captain James O'Shaughnessy Beveridge, R.A.M.C., was reported as killed in action, in the casualty list published on December 6th. He was educated in Dublin, and graduated M.B., B.Ch., and B.A.O. of the National University of Ireland in 1915. He took a commission as lieutenant in the Special Reserve of the R.A.M.C. on February 2nd, 1914, joined after qualifying, and was promoted to captain after a year's embodied service.

CAPTAIN A. COWE, R.A.M.C.

Captain Archibald Cowe, R.A.M.C., was killed in action on December 2nd, aged 28. He was the son of the late

Archibald Cowe, J.P., and was educated at Watson's College and at Edinburgh University, where he graduated M.B. and Ch.B. in 1913, and, following the award of a King Edward VII British-German studentship, went to Germany, and studied for a year at Freiburg. He took a temporary commission as lieutenant in the R.A.M.C. on February 7th, 1915, and was promoted to captain after a year's service.

CAPTAIN ARTHUR M. FISHER, R.A.M.C.

Captain Fisher, who was reported in our issue of November 3rd, p. 599, as killed in action, graduated at McGill University in 1914, and was attached to the surgical staff of the Royal Victoria Hospital, Montreal. He was one of four Canadian surgeons chosen to join the British forces in the summer of 1915, and was appointed medical officer on a transport running between England and Alexandria. The vessel was torpedoed, but Captain Fisher was saved, although he lost all his personal belongings. Some months later he was invalided to England suffering from an intestinal affection and underwent a serious operation, after which he returned to Canada to recuperate. The following

autumn he returned to England and subsequently to France.

CAPTAIN G. WALKER, M.C., R.A.M.C.

Captain Gideon Walker, M.C., R.A.M.C., was killed in action on November 27th, while attached to a field ambulance, aged 27. He was the youngest son of the late Gideon Walker, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1912. He took a temporary commission as lieutenant on September 20th, 1914 and was promoted to captain after a year's service. He gained the Military Cross on November 14th, 1916.

Died of Wounds.

MAJOR T. J. FRIZELLE, A.A.M.C.

Major T. J. Frizelle, Australian Army Medical Corps, died of wounds in a British Red Cross Hospital on December 2nd. He was the eldest son of the late Dr. Thomas Frizelle, of Sydney.

CAPTAIN G. HISLOP, R.A.M.C.

Captain George Hislop, who has died of wounds, was the youngest son of Mr. James Hislop, of Glasgow. He graduated M.B., Ch.B. Glas. in 1913, and obtained a commission early in 1915, being promoted to captain after a year's service. He went with the mounted brigade field ambulance to Gallipoli, and later served in Egypt.

CAPTAIN K. A. MACCUSH, C.A.M.C.

Captain Kenneth Angus MacCush died in November in a French hospital of wounds received while on duty, aged 43. He was born at St. Peters, Nova Scotia, and graduated at Dalhousie University, Halifax, in 1903. Some years later he went to Edinburgh for post-graduate work. He was in practice at Glace Bay, Nova Scotia. He went overseas with the hospital unit supplied by the St. Francis Xavier University, Antigonish, Nova Scotia, and after serving for a short time in a hospital in England proceeded to France.

Lost at Sea.

DR. A. J. T. SWANN.

The Elder-Dempster liner *Apapa* was torpedoed and sunk by a German submarine, with much loss of life, on the morning of December 5th, near Liverpool, on the voyage home from South Africa. Among those reported lost was Dr. Alexander James Thompson Swann, of North Nigeria. He was educated at Glasgow University, where he graduated M.B. and C.M. in 1898, also taking the D.P.H. of the Scottish colleges in 1913. After serving as surgeon to His Majesty's transport *Jelunga*, and as a civil surgeon in the South African war from 1900 to 1902, receiving the medal, and filling the posts of resident assistant medical officer of the Croydon Borough fever hospital and of resident medical officer of the Croydon and Wimbledon joint small-pox hospital, he joined the West African Medical Service, and was on his way home on leave when he lost his life.

Wounded.

Lieut.-Colonel H. W. Carson, R.A.M.C.

Lieut.-Colonel T. M. R. Leonard, West African Medical Staff.

Major J. B. Mackenzie, Australian A.M.C.

Captain J. Alexander, R.A.M.C. (temporary).

Captain T. E. C. Clarke, M.C., R.A.M.C. (T.F.).

Captain C. B. Davies, M.C., R.A.M.C. (temporary).

Captain H. N. Goode, R.A.M.C. (T.F.).

Captain L. J. Hunter, Australian A.M.C.

Captain D. A. Kennedy, R.A.M.C. (temporary).

Captain T. R. Kenworthy, R.A.M.C. (temporary).

Captain W. J. E. Mingie, Canadian A.M.C.

Captain T. Stansfield, R.A.M.C. (temporary).

Lieutenant M. B. Taylor, R.A.M.C. (temporary).

Missing.

Captain R. T. Bruce, R.A.M.C. (T.F.).

DEATHS AMONG SONS OF MEDICAL MEN.

Clarke, Paul Brooks, Lieutenant Canadian Infantry, only son of Dr. W. F. Clarke, of Toronto, killed October 28th, aged 21.

Gilbertson, Graham Sidney, Second Lieutenant Bedfordshire Regiment, son of Dr. J. H. Gilbertson, of Hitchin, killed November 28th, aged 19. He was educated at Hitchin Grammar School and in H.M.S. Worcester, where he was champion swimmer. He passed an examination for the R.N.R. in 1915, but was rejected for colour blindness. He then joined the Inns

of Court O.T.C., got a commission last April, and went to the front in August.

Hains, Cyril L., Lieutenant Royal Air Service, son of the late Dr. Hains, of Totnes, Devon, reported missing on May 26th, now presumed killed on that date, aged 21.

Hall, Geoffrey, M.C., Lieutenant Royal Fusiliers, son of Dr. Edgar A. Hall, of Surbiton, killed about November 24th, aged 20.

Halley, Edward Harland, Lieutenant Royal Field Artillery, attached Trench Mortar Battery, killed in action on November 26th, aged 24, only child of Dr. W. Halley of Fulham Road. He was educated at the Imperial College, Windsor, and at Epsom College. He returned from Singapore, where he was in business, in 1915 to join the army, and obtained his commission. He went to France in August, 1915.

Mann, Alexander David, Second Lieutenant Seaforth Highlanders, youngest son of Dr. Mann, of Fochabers, late of Nairn, killed November 20th, aged 23.

Nevitt, George R., Captain West Yorkshire Regiment, son of the late Mr. J. G. Nevitt, surgeon, of Leeds, killed in action, aged 28. After training in the Leeds University O.T.C. he received his commission in October, 1914, and was promoted to captain in June, 1915. He went to France in December, 1916, and was wounded in February last.

Parnell, Mervyn Edmund, Captain and Adjutant 36th Indian Cavalry, Jacob's Horse, youngest son of Dr. G. C. Parnell, of Forest Hill, died of wounds December 1st, aged 31. He was born on December 23rd, 1885, got his commission in the Gloucester Regiment on January 16th, 1907, was appointed to the Indian Army on March 5th, 1909, became lieutenant on April 16th, 1909, and got his troop during the present war.

MEDICAL STUDENT.

Strettell, William Michael Dashwood Stirling, Lieutenant Highland Light Infantry, attached Royal Flying Corps, killed November 28th, aged 24. He was the only son of the late George W. Strettell of the Indian Forest Service, and when the war began was a medical student at St. Andrews University, where he was a member of the O.T.C. He got his commission in the Highland Light Infantry on August 15th, 1914, was promoted to lieutenant in 1915, and went to France in May, 1915, with the King's Own Scottish Borderers. He was wounded at Ypres, invalided home, and served in the first garrison battalion of the Royal Scots in Lemnos and Egypt. He joined the Royal Flying Corps in the autumn of 1916, and went to the front again on September 29th, 1917.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

MENTIONED IN DISPATCHES.

A DISPATCH from Sir Douglas Haig, dated November 7th, 1917, contains a list of names of officers, ladies, non-commissioned officers, and men serving, or have served, under his command during the period February 26th to midnight, September 20th-21st, 1917, whose distinguished and gallant services and devotion to duty he considers deserving of special mention. The following medical officers are included in the first list; further lists will be issued later, that referring to the medical service on December 24th.

ROYAL NAVY.

Surgeons W. J. McCracken, D.S.O., M.C., and A. G. Williams.

STAFF (ARMY).

Brevet Colonel A. J. MacNab, F.R.C.S., I.M.S.

Lieut.-Colonel T. A. Granger, M.B., I.M.S.

Captain G. W. Ellis, R.A.M.C.

ATTACHED ROYAL FLYING CORPS.

Temporary Lieutenant (temporary Major) J. L. Birley, M.B., R.A.M.C.

One quartermaster-sergeant and one sergeant of the Royal Marine Medical Unit are also mentioned.

NOTES.

THE names of Major (temporary Lieut.-Colonel) B. H. V. Dunbar, D.S.O., M.D., R.A.M.C., and Captain J. A. Davies, R.A.M.C. (T.F.), serving with the British Forces in Italy, have been brought to the notice of the Secretary of State for War for distinguished service in the field.

The Croix de Guerre has been awarded by the French Government to Lieutenant R. J. Helsby, R.A.M.C., of Bangor, in recognition of valuable services rendered to French soldiers during an emergency resulting from an enemy attack in France.

THE Senior Military Medical Association has been founded in order to give doctors who by reason of age, physical defects, or teaching obligations are unable to join the American Medical Reserve Corps the opportunity of giving part or whole time service in their own towns or elsewhere in the United States. Dr. W. W. Keen of Philadelphia, who served as an army surgeon in the civil war, is the president of the association.

Scotland.

THE Glasgow and West of Scotland Radium Committee (212, West George Street, Glasgow) announces that practically the whole of the radium has been fractionated, and that there has been an increasing demand for it. At the present time it is being used to the full capacity, and there has for the last six months been a waiting list of applications for preparations of various kinds. The Committee has sufficient funds to meet present requirements.

THE CURE AND CARE OF CANCER.

The late Mr. George Fisher Melville, advocate of Edinburgh, who died last July, has bequeathed a sum estimated at about a quarter of a million to trustees to be devoted to the cure and care of cancer. It is considered that the deed is so widely drawn that the money can be used either for the purposes of the foundation of a school of research, or a hospital, or both. The money does not become immediately available for this purpose, as the testator left annuities to his wife, cousins, and certain friends and servants. He directs that "the whole is to be kept and accumulated till the whole of the beneficiaries are dead, and the residue is to be devoted to the cure and care of cancer."

ORTHOPAEDIC TREATMENT OF DISABLED MEN.

On December 6th the Minister of Pensions formally opened the Orthopaedic Institute established at Glasgow, by agreement with the Joint Disablement Committee for the South-West of Scotland, including the counties of Lanark, Renfrew, Dumbarton, Argyll, Bute, Ayr, Stirling, Kinross, Wigton, Kirkcudbright, and Dumfries. The centre is for the benefit of discharged sailors and soldiers who have ceased to be in-patients of military hospitals. The patients will be men recommended for treatment as out-patients, also men in training for a new occupation, or who may be engaged at their ordinary work; they will leave their training or occupation for the time required each day for treatment. The centre is equipped with radiant heat baths and electrical appliances. A similar centre was opened in Aberdeen a month ago, and another is being established at Dundee. The Ministry of Pensions has formally approved the arrangement between the corporation of Edinburgh and the Joint Disablement Committee for South-East Scotland for the provision of an orthopaedic centre at Tynecastle, Edinburgh, for the treatment of disabled soldiers and sailors. Tenders have been accepted for the erection of the building.

MEDICAL BENEFIT IN SCOTLAND.

Mr. W. M. Marshall, Clerk to the County of Lanark Insurance Committee, in a pamphlet of less than fifty pages has succeeded in conveying in an interesting manner an astonishing amount of information as to the administration of medical benefit in Scotland. As secretary of the Scottish Association of Insurance Committees he has exceptional opportunities of knowing the work of the various areas, and though on occasion he has not spared criticism of the panel practitioners, his desire to be fair all round is evident. There are, he states, fifty-six Insurance Committees in Scotland, each dealing with a suitable area, as contrasted with 309 public health authorities, many of which are too small to carry out any important measures of health. One of the greatest difficulties with which the committees have to deal is the enormous number of removals of insured persons. In Glasgow, for example, in 1916 there were 42,051 names added to the list of insured persons and 48,336 removed. He gives strong grounds for the view that it would have been impossible for medical benefit to have been administered by the approved societies, considering their great number and the difficulty which free choice of doctor entails. Referring to the treatment given by the panel practitioners, it is satisfactory that during the four years of the working of the Act only one case has occurred where a practitioner's name had to be removed from the panel for negligence or careless treatment, and sufficient particulars are given to show that the treatment actually given includes not merely minor ailments, as was stated by the Fabian Committee, but often the most serious forms of illness. The report of the

Fabian Committee is characterized as "a travesty of the actual position." Details are given as to the relative proportion of visits to consultations at the surgery in towns and country districts. In Edinburgh, for example, the number of consultations is twice as great as the number of visits, while in the county of Midlothian the visits exceed the consultations by 50 per cent. The hardships of the country doctors are vividly depicted, and figures are given to prove that in equity to the country doctor some readjustment of the terms of service are necessary. Dealing with certification, it is satisfactory to learn that though a certain amount of carelessness on the part of a few doctors has caused trouble, the number of complaints from approved societies is remarkably low. The vagaries of the Drug Fund in different districts are described in detail, though Aberdeen is said to be almost the only area where the demands on the fund have been so high as to endanger its solvency. The difficult problem of providing an adequate service for the Highlands and Islands is discussed at some length, and it appears that out of the sum of £42,000 provided by Parliament for this special purpose the actual expenditure in 1916 was only about £20,000, as, owing to war conditions, it has not been possible to give full effect to the schemes proposed. A final chapter deals with the supplementary services proposed, such as the provision of specialists and consultants, the extension of nursing facilities, hospital accommodation, and laboratories for research, all intended to complete the scheme of medical benefit. Here again war conditions have interfered with the measures proposed, but considering the conditions, the author concludes that, on the whole, medical benefit, as provided under the Act, has been not merely satisfactory but of enormous benefit to the insured workers. The pamphlet is undoubtedly a valuable contribution to the study of the administration of the Insurance Acts in Scotland, and provides a large amount of information not otherwise easily obtainable.

Ireland.

ULSTER MEDICAL SOCIETY.

THE third meeting of the session was held in the Medical Institute, Belfast, on December 6th, with the President, Dr. W. D. Donnan (Holywood), in the chair. Dr. J. E. MacIlwaine read a paper on a clinical study of some functional disorders of the heart which occur in soldiers. Among some 3,000 cases he found about 1,000 of the irritable heart of Da Costa. Dealing with the etiology, he could not assign any one of the usual causes. Major Houston had examined the urine in 100 cases and found nothing wrong bacteriologically. Trauma, gassing, tobacco, hyperthyroidism were all passed in review, and the psychology of the patient and the disturbed and perverted functioning of the sympathetic nervous system were considered. Numerous examples and cases were given. Dr. W. Calwell said that the paper was so full, giving evidence not only of large experience but also of research, that it would not be fair to take up the criticism on such an important subject in the short time left at the disposal of the meeting that night. He proposed that the discussion be adjourned. This was seconded by Professor Lindsay and passed. Mr. E. B. Turner (London) gave a short address on what had been done in England by the National Council for Combating Venereal Diseases. He said that the Local Government Boards of England and Scotland had both, after some pressure, consulted the medical profession in the preparation of their schemes, and he was glad that the Board for Ireland was going to do the same. There was no use in formulating a cut and dried scheme and thrusting it upon the profession. Professor Lindsay proposed a hearty vote of thanks to Mr. Turner for his address, and as vice-chairman of the local council gave an account of what had been done. The motion was seconded by Professor Sir John Byers, supported by Dr. Bailie, M.O.H. Belfast, and passed with acclamation. There is a strong fear in many of the country districts that the county councils will adopt schemes which will be unworkable without the discussion with the local profession now recommended by all the Local Government Boards, and it is felt that measures should be taken to ensure practical schemes.

Canada.

A RESEARCH FOUNDATION IN PREVENTIVE MEDICINE.

MENTION has already been made in the *JOURNAL* of the work being carried on in the antitoxin laboratories of the University of Toronto under the direction of Major J. G. Fitzgerald. Some months ago a large farm was given to the university by Colonel Albert Gooderham for the purpose of research in preventive medicine and the preparation of serums and vaccines, and the Connaught laboratories which have been established on the farm were officially opened by the Governor-General on October 25th. Sir William Hearst, the Premier of the Province of Ontario, announced the establishment of the first research foundation in preventive medicine in Canada. At the next session of the Legislature an endowment fund of 75,000 dols. would be voted for research in preventive medicine. The income would be devoted entirely to research as the Connaught laboratories are self-supporting. A further announcement was made that a sum of 25,000 dols. was available from another source, and that the income derived from that also would be devoted to research. The research work undertaken will be along the lines of that done at the Pasteur Institute in Paris, the Lister Institute in London, and the Rockefeller Institute in New York.

MEDICINE AND THE STATE.

In his presidential address before the Toronto Academy of Medicine, Dr. D. J. Gibb Wishart made the observation that the failure of the Canadian Government to take advantage of the expert technical knowledge of leading members of the profession stood out with greater clearness in comparison with the steps taken by the Government of the United States to avail itself of the assistance of authorities in every branch of medicine. With one exception, when the Medical Council of Canada was invited to offer some suggestions, not one of the medical associations, universities, or scientific bodies had been consulted by the Government or the Department of Militia. The passage of the Military Service Act had raised many problems in which it would seem that the intelligent co-operation and advice of leaders of the medical profession would be of service—for instance, the number of army surgeons that the country could supply, the provision of adequate medical attention for the civilian population, the exemption or non-exemption of medical students, and the utilization to the best advantage, either at home or overseas, of the services of men of high professional training or ability. The Canadian Medical Association, at its annual meeting, had passed a resolution to the effect that the entire profession should be mobilized. The great and increasing demands of the war made it important that this should be done. The lack of organization had had a deterrent effect upon the proper presentation of medical opinion in Canada. The Ontario Medical Association had been labouring for some years to evolve a plan which would improve this state of affairs, and it was hoped that the organization would be completed very soon. The work of the Army Medical Service had been handicapped by the relatively low rank with which medical officers served; a low estimate had been placed upon the service as a result of defective legislation which ought to have been remedied long ago. Efficiency alone should be considered, and the advice of the members of the profession who had gained experience through service should be sought. In discussing the effect of the war upon medicine, Dr. Wishart said that military discipline had taught the relative insignificance of the individual as compared to the good of the greater number. The results achieved in the field of preventive medicine prepared the way for State control. The sign of the times was that the day of the competitive physician and surgeon was over, and that, as his training was now paid for largely by the State, his employer hereafter might be the same body. It was probable that teachers in final and clinical subjects in the future would be whole-time men paid by the State at a salary commensurate with their responsibility.

Commenting editorially on Dr. Wishart's address, the *Canadian Medical Association Journal* gives the following as three demands made by the profession of the authorities at Ottawa:

1. A seat upon the militia council for the surgeon-general.

2. The appointment of a permanent surgeon-general whom the profession can trust and respect.

3. The appointment of an advisory committee to the surgeon-general of the leaders of the profession, nominated by the Dominion and provincial associations and by the universities.

THE VANCOUVER MILITARY HOSPITAL.

The Vancouver Military Hospital, which was opened by the Lieutenant-Governor of the province of British Columbia in September, is an annex to the Vancouver General Hospital. It contains accommodation for 320 returned soldiers. A sum of 60,000 dols. was subscribed by the people of Vancouver to pay for the building and equipment of the institution; the beds and bedding were supplied by the Military Hospitals Commission.

Correspondence.

INTRAVENOUS INJECTIONS OF GUM IN LOW BLOOD PRESSURE.

SIR,—In your valuable article in the *JOURNAL* of December 8th last there is a slight misreading of a statement made by me in an article in the *Archives médicales belges*. In that article I point out that a 6 to 7 per cent. solution of gum has a viscosity and a colloidal osmotic pressure equal to those of blood. Accordingly, if the best effect in replacing blood lost by hæmorrhage is to be obtained, solutions of this strength should be used. There is no doubt, however, that the addition of only 2 per cent. confers properties greatly superior to those of any solution containing salts alone. At the time of my visit to the casualty clearing stations this solution was being used. Hesitation was felt in using solutions of a greater strength since they had not been successful in one or two apparently hopeless cases. But the stronger solutions have now come into more general use.

In a large series of experiments on cats I have found that solutions of 5 per cent. or above can always be depended upon to restore permanently the low arterial pressure due to loss of blood. If the loss has not been great, 4 per cent. is frequently successful, and sometimes even 2.5 per cent. The height to which the pressure is raised by a given quantity of solution depends on its strength, as also does the length of time during which it can be relied upon to maintain the pressure. A report presented to the Shock Investigation Committee is now in the press, and the solution recommended there is one containing 6 per cent. of gum and, as salt necessary to make the solution isotonic with the blood corpuscles, 2 per cent. of sodium bicarbonate. The latter is added, in place of the usual sodium chloride, in order to combat the diminution of alkaline reserve usually met with in shock, a condition exaggerated by operation.

The impression might be conveyed by the sentence in your article that 2 per cent. gum or the 2.5 per cent. gelatin of Hogan's solution is all that is necessary. This would, I think, be unfortunate.—I am, etc.,

London, W.C.1, Dec. 10th.

W. M. BAYLISS.

TROPICAL MEDICINE AND HYGIENE.

SIR,—On referring to my article on British contributions to tropical medicine in your issue of July 28th I regret to find that I made two somewhat serious omissions. I failed to mention Dr. H. G. Waters's work (1909) on bronchial spirochaetosis in epidemic form in India. Another omission I must apologize for, inasmuch as I failed to mention work of Dr. Dutton and his associate Dr. J. L. Todd, which in a measure anticipated some of Sir William Leishman's observations on the development of the spirochaete of tick fever in *Ornithodoros moubata*. I regret the omission all the more as Dr. Dutton fell a victim to relapsing fever contracted in the course of his work on that disease in Central Africa.

Probably I made other omissions. The extent of the subject and the exigencies of space must be my apology.—I am, etc.,

London, W., Dec. 11th.

PATRICK MANSON,

THE VALUE OF THE SANATORIUM.

SIR,—If your leading article of December 8th be right, that the general outcome of the recent discussion at the Medical Society on the value and limitations of sanatorium treatment is that, from the public point of view, sanatorium treatment has proved a failure, I would crave a little space to record an emphatic dissent from the finding.

Without dwelling on details of the discussion, I should like to underline the view that we are not yet in a position to appraise the value of the sanatorium from the public point of view.

Let us keep the facts in mind. It is little over four years since the publication of the report of the Departmental Committee which was appointed to "report upon the consideration of general policy in respect of the problem of tuberculosis in the United Kingdom in its preventive, curative, and other aspects, which should guide the Government and local bodies in making or aiding provision for the treatment of tuberculosis in sanatoriums or other institutions, or otherwise." That report made certain recommendations. In particular, it proposed the adoption throughout the country of a co-ordinated scheme of anti-tuberculosis institutions and measures, which, if they are to be effective, must be mutually interdependent. The sanatorium was recommended as *one* element in a co-ordinated plan. The report formulated the functions of the sanatorium proper in relation to the reception and treatment of early cases of tuberculosis, and likewise defined the functions of the other elements in a co-ordinated scheme of operations.

But how have things worked out? In the first place there was delay, from one cause or another, in framing local schemes, when such had not existed previously. There was a good deal of fumbling—innocent and perverse—with regard to what constituted a sanatorium, with inevitable drifting in wrong directions. The sanatorium was frequently allowed to become a dumping ground for every sort of case, the undesirable (incurable) being especially in evidence. The recommendation of the Departmental Committee that such cases should have hospital treatment (as opposed to sanatorium treatment in the strict sense) was commonly lost sight of. The result has been hopeless confusion, the piling up of long waiting lists, and the blocking of sanatoriums against suitable cases, until, in many instances, the suitable have perforce lapsed into the unsuitable. In this way an interminably vicious circle has been established.

Add to this the world crisis. The war has been made the apology for difficulties of every kind. Even schemes which were getting under way have been badly crippled. Sanatoriums specially erected for the treatment of tuberculosis have been transferred to war purposes, and buildings which had been planned or were being erected for the purpose have been held up. The outcome is that in few centres has an effective antituberculosis scheme been put in operation. In many cases there is hardly the skeleton of an organization.

In the midst of the welter and confusion men are asked for an opinion as to the value and limitations of the sanatorium. The immense significance of sanatorium treatment to individual tuberculous persons is acknowledged by the great majority of those who have been in a position to judge of practical results. The value of the sanatorium is emphasized when contrasted with the hopelessness of presanatorium treatment.

It is another business to pass from the obvious advantage in individual cases, and attempt to estimate the larger results for the country. The larger results of what? Of the imperfect—often half-hearted—adoption of a programme of antituberculosis measures, and the interruption and disorganization of the programme almost before its inception. And this in relation not to a short, well-defined, infection such as enteric or plague, but to an infection whose infinitely variable course we are just beginning to understand, and whose duration from start to finish is to be measured for the most part by years.

In the scheme of antituberculosis measures the sanatorium was established to effect a special purpose in the campaign—namely, the treatment of early and curable cases. It was not projected "for the patching up of damaged lives." Its use for the latter class has been the result of incredible muddling on the part of persons who, without the training or patience to understand the issues,

have adopted the easy creed that one man's guess is as good as another's. Hence confusion worse confounded.

I agree with you that "other means" (than the sanatorium) "must be found for the diminution of the case incidence and the lowering of the death-rate." Surely no student of tuberculosis seriously looked to the sanatorium for these results, save as late and indirect consequences. They will slowly accrue from year to year. They will definitely affect the situation, in proportion as the great object lesson of the sanatorium is carried into the homes of the people and comes to mould our policy and practice in relation to housing (using the term to include the arrangements which ought to prevail where men congregate in groups under cover).

The vital problems presented by tuberculosis will be solved in proportion as its protean character is rightly apprehended. The complex issues involved must first be disentangled and clarified. The natural history of an infection which may kill in a few weeks or—with alternating recessions and exacerbations—may last a long lifetime without killing, calls for more consideration than it commonly gets in the medical schools. In framing schemes of prevention and treatment each element must be precisely adapted to its given purpose. The several elements must be correlated with care, and there must be no cross purposes. The organization and administration of measures and institutions for the prevention and control of tuberculosis require knowledge, experience, and skill. These will come with the development of operations and the better training of our students. Meantime it is hardly fair to complain of the failure of machinery to do work for which it was not projected, nor very sound to demand the adoption of other machinery when the prescribed machinery—far from having failed—has not been given a trial.—I am, etc.

Edinburgh, Dec. 10th.

R. W. PHILIP.

SIR,—That the sanatorium treatment of tuberculosis in this country has disappointed the exaggerated hopes expressed during its inception need surprise no one. Years ago Walther of Nordrach discontinued his sanatorium for poor persons because, as he told me, he found it useless, since they practically always relapsed on returning home. The true *preventive* treatment of tuberculosis is proper housing, wages, and conditions of work, and there is no cheap short cut.

But I feel sure that sanatorium treatment as a *curative* measure might have done more for us than it has. It has been proved to the hilt that our prevalent rain-bearing winds increase phthisis mortality amongst populations exposed to them, and, with much probability, that they are injurious to phthisis patients. Yet how much care has been taken in this country to choose sites for sanatoriums where they are sheltered from these winds? I am not at all surprised that the results in some of the sanatoriums erected during the last two decades have been disappointing. Indeed, I should be greatly surprised if they had not. The Germans, who recognized and used the discovery of an Englishman (Dr. MacCormac of Belfast), made no such mistake in their use of open air. Görbersdorf in Silesia, where Brehmer built his sanatorium in 1862—the first of their ventures—lies in a well-sheltered valley. Nordrach in the Black Forest, where Walther misled his English visitors with the myth that he laid no stress on climate, stands in a very sheltered valley which he had carefully chosen after months of search, as he admitted to me. On the other hand, the Falkenstein sanatorium, looking out west and south from the slopes of the Taunus, was not a success.

I am no believer in the German "legend." A visit to Berlin on the occasion of Koch's tuberculin fiasco in 1890 dissipated my delusions as to Teutonic superhumanity. But, besides their wonderful industry and self-advertisement, the Germans have a faculty of which we, whose contributions to civilization have been so vastly greater, might well partake—namely, perceptiveness. It took us more than fifty years to perceive the value of open air in phthisis. May one hope that in another fifty we will perceive the effect of exposure to strong rainy wind?

If we built our sanatoriums, as we ought to do, on quickly drying soil, under moderate rainfall, in pure, dustless, fogless air, with abundant sunshine and protection from wind, particularly from rainy wind, and at least a quarter

of a mile inland from the sea, selecting preferably a district of known low phthisis mortality, our results, I am confident, would be much better than they are, and we should not now be in danger of running from one extreme of opinion to another. Sanatoriums, I am convinced, are valuable where properly situated. Where wrongly situated, I believe they may be worse than useless.

One other word. Some time ago I tried to discover the effect on sanatorium statistics of the sanatorium site. I had to give up the inquiry. For I found so many cases were regarded as cured consumption in which, bacilli having never being discovered, the diagnosis, in my opinion, remained in doubt, and that in many sanatoriums exact statistics were not obtainable.—I am, etc.,

Exeter, Dec. 8th.

W. GORDON.

SIR.—In your leader (p. 767) summing up the expert opinions expressed at the Medical Society discussion you say that "it would seem that sanatorium treatment from the public point of view has proved to be a failure, although it has rendered very material service to individuals."

Doubtless this is a very fair statement of the case; but still not really fair to sanatorium treatment as such. At present the after-care of the patient is the difficulty, and the immediate result of treatment is judged by that, which is hardly fair, as important considerations are omitted.

In Wales and Monmouthshire the work of the Welsh National Memorial Association, which administers sanatorium benefit, has been much hampered by the following difficulties:

About 40 per cent. of tuberculosis cases never come to the notice of the tuberculosis officers.

The vast bulk of the public and a small proportion of the medical profession do not trouble to distinguish between hospital and sanatorium cases.

Some insurance committees and medical attendants are insistent on sending hospital cases to sanatoriums, thereby placing the tuberculosis officer and sanatorium superintendent in a difficult position. Hospital cases, acute and advanced, are then expected to do as well as the proper early case.

The advanced case which has, perhaps, done remarkably well and come out robust in health, with his tuberculosis in a sealed condition, is expected to take up the threads of his previous existence, with every circumstance tending to interfere with his leading the disciplinary life which he led at the sanatorium.

The exigencies of the war have interfered with the general work of the Association, and this is doubtless true of similar agencies in the rest of the United Kingdom. It is, however, very encouraging to receive very many letters from thankful patients who have "joined up" and done well in the army and navy, or have settled down into busy public life.

Sanatorium treatment should not wholly be condemned if "peradventure ten persons only are saved." Doubtless a successful State medical service will greatly assist in solving this as well as many other medical problems.—I am, etc.,

Newport (Mon.), Dec. 8th.

J. LEWIS THOMAS.

HOW IS THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS TO BE MADE?

SIR.—One cannot take exception to the desire of the Medical and Panel Committees of Manchester if they felt the need to revise their knowledge of the physical signs of pulmonary lesions, but when they publish their joint deliberations in the form of a memorandum which, with all its up-to-dateness, contains nothing which cannot be found in any medical textbook, and when its apology contains assertions which reflect anything but credit on their colleagues, what end have they in view? If they think that there are practitioners who do not keep in touch with the literature of their profession, do they really believe that they do any good by seeking to buttonhole those men through the Insurance Committee? Incidentally, it always appears to be some third person who requires the assistance. In Halifax the same thing happens. I have been informed that the Halifax Panel Committee regarded it as

a "most excellent memorandum," and advised its publication. Evidently our local committee does not require it, or how do they know that it is a most excellent memorandum? Did that criticism not demand knowledge based upon experience? Yet they advised the Insurance Committee to publish it, evidently for the benefit of their colleagues. If one resents this pharisaical attitude, can one be much blamed?

If the opinion of the Manchester Committees is correct, and if one accepts the need of this memorandum—and one would be justified in doing so—as an indication of the average practitioner's professional knowledge, then there will be little occasion to comment if the general public show little confidence in the profession.

I would feel sorry if Dr. Sutherland regarded my letter in any way as an attack on his qualifications as a tuberculosis officer; but, speaking generally, one must not lose sight of the fact that appointments as tuberculosis officers under the insurance scheme do not qualify those men to be recognized as tuberculosis experts. To be an expert one requires to be as conversant with the beginnings of a disease as with its later stages, and in view of their position as tuberculosis officers, their experience in the difficult problems of the earlier symptoms must be limited. It may be that the more capable the general practitioner becomes the greater will be the field of usefulness of the officers; but it is obvious that the more capable the general practitioner becomes the less need will there be to call in the "expert."

This point of view is of importance because of the present tendency to multiply the "experts," and it is hard to say whether ultimately it will be any easier for the practitioner to diagnose the particular "expert" required for his patient than it is at present to diagnose the particular disease from which the patient is suffering.

In regard to the letter of Dr. Lachlan Grant, it was not my intention to commence a discussion on the early symptoms of pulmonary tuberculosis. I hope as a general practitioner I am no more interested in the need for the early diagnosis of pulmonary lesions than in the need for the early diagnosis of many other diseases. There was no intention to give expression to these thoughts if the memorandum had not called for a protest.—I am, etc.,

Halifax, Dec. 9th.

A. GARVIE.

THE RESERVE POWER OF THE HEART.

SIR.—The report upon soldiers returned as cases of "disordered action of the heart" of the Medical Research Committee in England has recently been supplemented by reports of the detailed clinical studies made by members of the staff, contained in No. 4, Vol. VI, of *Heart*. The most striking features of these excellent and very detailed studies are, first, the negative conclusions as to the etiology and pathology of this syndrome, and, secondly, the positive conclusion that graduated exercises cure a large proportion of the patients.

These patients show certain symptoms which, to our mind, are most significant—breathlessness and blood pressure and pulse reactions to exercise. The authors state that:

The response of the respiratory rate to exercise is a very exaggerated one.

Again:

None of our patients are capable of such effort (that is, amounts of work healthy young adults are capable of); equal distress and similar pulse rates and systolic pressure are produced by smaller amounts of work or work done more slowly. It is clear that if we chose a given amount of work as a stimulus and apply the stimulus to healthy controls and to our patients, the latter react to the stimulus in an exaggerated fashion. The pulse rate rises much higher than in controls, and the high rate is longer sustained, the blood pressure rises higher and the raised pressure is longer sustained than in controls; the summit of the blood pressure is not delayed,* however; breathlessness, fatigue, and palpitation are also much more in evidence.

It seems to us very clear that the patients who presented the above symptoms were suffering from a decreased cardiac reserve power. The fact that so many of them were cured

* The summit was not delayed because the authors in each experiment stopped increasing the work just as they were about to reach a "delayed rise." The controls were given from one-third to four times more work than the patients (comparing the maximum amounts given). Had the authors been a little more persistent they would have found the "summit of maximal pressure is delayed" exactly as they found it was in normal patients, and with decidedly less work.

by graduated exercises affords additional and convincing proof. The neurotic symptoms which were often present are not necessarily a sequence of the decreased cardiac reserve power, but probably are simply a concomitant. Very possibly they are caused by the same factors which produced the decrease in cardiac reserve power.

We frequently see these patients with decreased cardiac reserve power in civil life, and graduated exercises cure them. One half of the patients described in the report dated the onset of symptoms a number of years back. Infections of various kinds contracted during service immediately preceded the onset of symptoms in another large group. The cardiac reserve power is always lowered after any infection of moderate severity. Anyone who has indulged in exercise too soon after a sojourn in bed with fever can appreciate the truth of this statement. The report takes cognizance of this etiological factor when it states that "convalescent treatment should be more prolonged than is often the case; a graduated system of re-training seems most desirable."

A group of patients is described who suffered from precordial pain, and in many instances hyperaesthesia of the chest wall, both accentuated by exercise. The circulatory reactions of this group to exercise are not given except in one instance, probably because it was inadvisable to carry out exercise experiments on account of their effect upon the pain. These patients are quite rare in civil life, and their subsequent histories would be of much value.

Objections may be made of our use of the term "cardiac reserve power." The heart's total capacity is made up of two component parts: one, the smaller, comprises the power expended in furnishing the requirements of the metabolism with the body at rest; the other, by far the larger, is utilized when physical work is performed. It is this potentially large component which is called into action by graduated exercises. Any expression which describes a definite function of a bodily organ has a perfectly legitimate use. In this instance the term "cardiac reserve power" denotes a most important function of the heart the variations of which are matters of personal experience to every man who has gone through a course of physical training. Our inability to measure the heart's reserve power directly is not a reason for ignoring its existence.

When the reserve power is impaired, not from organic disease of the heart but from any one of numerous causes, there is presented a characteristic clinical picture which to our mind the authors of the report have described quite accurately. The neurotic symptoms from which these patients suffer do not alter the significance of the respiratory and circulatory reactions to work or the significance of the curative effect of graduated exercises.—I am, etc.,

THEODORE B. BARRINGER, jun.,

Associate Attending Physician, New York Hospital.
New York, U.S.A., Oct. 23rd.

LAY RADIOGRAPHERS AND ELECTRO-THERAPEUTISTS.

SIR,—Radiography and radiotherapy have now been used over a sufficiently lengthy period (twenty-one years) for us to be able to form a just estimate of their true value as aids to diagnosis and treatment.

The prophecies made in the early days as to their ultimate value have been more than surpassed and to-day they stand higher than ever in the estimation of the profession as a whole. It is quite unnecessary to dilate upon their usefulness, and it suffices to say that modern war surgery largely owes its success to the knowledge afforded by the application of the *x* rays.

Notwithstanding all this, the teaching of radiography has no place in the medical curriculum, and we are informed that in many of our largest general hospitals the *x*-ray departments are run entirely by laymen, some of whom are actually engaged in private *x*-ray work on their own account. Is it not time that the staffs of these hospitals be enlightened as to the great wrong they are doing to the large body of their professional brethren who have specialized in this branch of work?

The state of things as set forth by Dr. Christopher Kempster (p. 778) is deplorable, and can only exist as an example of the irresponsible and thoughtless attitude adopted by some members of the profession.

It is evident that these unqualified radiographers who

practise on their own account must either be supported by the members of the medical profession, or they are giving advice and treatment, therefore constituting themselves unqualified practitioners.

Ten or twelve years back we were told that a surgeon who had to rely upon the *x* rays for his diagnosis was unworthy of the name, and students were advised not to attend the *x*-ray department as they might learn to rely upon the rays rather than upon their own personal judgement. Nowadays it may be said with absolute truth that a surgeon who does not apply the *x* rays in suitable cases is negligent and has not the best interests of his patient at heart. Surely it is now time that the radiographer was accorded his proper position and that the important branch of medical work was protected.

As regards the lay practice of electro-theraputists, the late Dr. Lewis Jones spent the greater part of his life in the attempt to raise this practice to its proper position, and to rescue it from the hands of the unqualified. In this attempt he was to a great extent successful, but at the present time it appears that there is a retrograde movement, to counteract which requires the joint efforts of the profession.

I can only trust that the British Medical Association will see its way at once to render the practice of radiography by laymen a matter of impossibility, and that the teaching of radiography will be made a compulsory part of medical education.—I am, etc.,

Birmingham, Dec. 10th.

J. HALL-EDWARDS.

SIR,—“Electro-therapist,” in his letter to the JOURNAL of December 1st, does not further his case very appreciably when he states that “lay bodies are more intelligent and conscientious than the profession” and that “the mass of the profession does not act professionally.” His own position in aiding the granting of certificates of competency in medical electricity (a branch of medicine strictly belonging to the medical profession) hardly puts him in a position to criticize his professional brethren. One would think from the tone of “Electro-therapist’s” letter that these lay societies are doing this from a philanthropic point of view. Let the profession take warning and stop this practice of electro-therapeutics by unqualified persons, and let those who are upholding this unqualified practice take heed before it is too late.—I am, etc.,

December 1st.

ELECTRO-THERAPEUTIST.

MIDWIVES (IRELAND) BILL.

SIR,—Dr. Power’s objection (p. 740) to the Midwives Bill (Ireland), as far as I can see, is concerned about a certain number of unqualified women at present practising as midwives, and who, under the Irish bill as well as under the English and Scottish bills, may be admitted to the register without examination.

It appears to me to be extraordinary that the legislators should be so careful of the vested interests of people who are carrying on an illicit trade to the detriment of the community. But if they be so anxious about them, why not put in operation Clause 21? Let the county councils advance these women the money necessary to get them a qualification. But let it be distinctly conveyed in the Act that from the very commencement no woman’s name shall be placed on the register except after examination and approval by the Board’s examiners. This, I think, will meet Dr. Power’s objection.

To my mind the most objectionable feature in the bill is the introduction into Clause 22 of a proviso, namely, “Unless the patient is entitled to medical relief under Section 9 of the Poor Relief (Ireland) Act, 1851.” Now there are paupers in England and Scotland and Wales, and medical officers paid to attend them. The amount of maternity benefit payable to the parturient woman is the same all over the United Kingdom. The Local Government Boards in England and Scotland have not considered it necessary to introduce such a proviso as this. Why should the Irish Local Government Board think it necessary to penalize Irish dispensary doctors, who are admittedly the worst paid and the hardest worked members of the community?

I will give one instance in my own practice of how this works out; I could give many others, and every dispensary

doctor in this county and every other county whom I have consulted on this matter could give any number of similar cases. About a fortnight ago I was called on a red ticket to attend a midwifery case six miles from my residence. On going there I found the district midwife in charge. I found it to be a perfectly natural labour, progressing rapidly and easily. I asked the midwife why she sent for me. She said she did not send for me; that she told the patient and her friends that a doctor was not necessary. I asked the husband why he fetched me all that way when the midwife told him there was no necessity. He said that "as there was a doctor paid to attend he did not see why he should not have him." This I consider a gross abuse of medical charity which should not be possible under the projected bill. If this man had to pay out of the maternity benefit (which is given him by the State for that very purpose) a small fee—say 10s., or even 5s.—he would not have put me to the expense and hardship of a twelve-mile drive. The fee should not be prohibitive in cases of necessity, and this can be secured by the Local Government Board retaining the power to fix it.—I am, etc.,

Graigue, co. Kilkenny, Dec. 3rd.

D. WALSH.

MEDICAL CERTIFICATES FOR RECRUITS.

SIR,—In the JOURNAL of December 1st, p. 742, Mr. F. Brinsley-Harper, as a member of the Appeal Tribunal for London and of the Russian Tribunal, has written a letter upon medical certificates. The suggestion put forward will no doubt be read by a large number of the profession who are a safeguard against men attempting to get relief when they are not entitled to the same.

I can assure Mr. F. Brinsley-Harper that there is no necessity for him to remind members of the profession that they have a duty to the State, and I resent his suggestion. No profession has made a greater sacrifice than the medical during the past three and a half years, and its members are fully aware of their duty in this respect without any reminder from him.

Mr. Brinsley-Harper carefully avoids any reference to the other side of the question—as to the attitude of some tribunals to the profession. For instance, I quote one case, and I know it is not an isolated one. A man came to me and I gave him a statement as to his definite malady, and it must have been quite obvious to any one that he was not fit for a soldier in any form. The man was a bootmaker and was asked at the tribunal the following questions: (1) How much have you paid for this certificate? (2) Do you make the doctor's boots? I trust this kind of attitude has now ceased.

Personally I have refused many certificates as soon as I was satisfied that the object of the application was to avoid service and there was nothing radically wrong with the man. On the other hand, when I have found a definite defect I have not given a formal certificate but a short history of the case, with no expression as to fitness or not for service, considering it was not my business.

If occasion arises I shall diligently observe Mr. Brinsley-Harper's suggestions, and I thank him for them.—I am, etc.,

Chichester, Dec. 3rd.

ARTHUR M. BARFORD.

SIR,—The note in the BRITISH MEDICAL JOURNAL of December 8th, p. 770, is one of vital importance to the honour of the medical profession no less than to the welfare of the general public. There is a very simple way of reaching these individuals without appearing to lecture the profession as a whole. And I venture to think that if the General Medical Council has a sound basis for its suspicions, the profession as a whole will uphold any action it cares to take to remove this blot.

This opens the other question, namely, the protection of the general public. Unwittingly a patient may be sent to one of these at present unknown "undesirables," and if he appears before a medical board he may fall under the suspicion of being party to a fraud. Is it not hard lines on the unfortunate patient? He is not aware that the consultant's name is under a cloud. His own case may be perfectly genuine, but for the foregoing reason he is prejudged.

I have at present a patient who was sent by another doctor to see a consultant who is one of the suspected,

and the patient, whose case is perfectly genuine, is suffering.—I am, etc.,

London, W., Dec. 9th.

A. MACBETH ELLIOT, M.D.

MEDICAL STUDENTS IN AND OUT OF THE RANKS.

SIR,—I am sorry to reopen this question, which I opened in the BRITISH MEDICAL JOURNAL of July 14th last, and which was discussed by others in following issues, but after reading Army Council Instruction (1715) in the JOURNAL of December 8th I am constrained to do so.

The result of this concession is *nil* to men in my position; it is worse, because it is, in my opinion, grossly unfair to many brave and patriotic students who joined the army at the outbreak of war, without waiting to be asked or waiting to be taken.

Many of these lads were below the age at which they have subsequently been conscripted; many of them were in the front line trenches at an age at which they are not even now compelled to join up.

To explain what I mean I take the case of my own son. At 16½ years he became a medical student and joined the O.T.C. of his university. Less than one year afterwards war broke out, and by the time he was 17½ he held a commission in an infantry battalion, and when just 18 he was in the trenches in Flanders, where he has been ever since, except for a time when he was invalided home with shell shock. Now, except from a sporting and patriotic instinct he need not have left his studies for another year, and then he would have been a second-year student instead of a first-year man, and would have now reaped the benefit of this new concession. Well may one ask in what way his patriotism has paid him—he has gained nothing and perhaps lost everything. In a letter in the JOURNAL of August 25th Dr. J. A. Ainscow wrote: "Most of the students, to their honour, required no urging. Those who sat tight and were blind and deaf to their country's call are now enjoying the benefits conferred upon them by the patriotism of others."

It will soon be three and a half years since my son opened a medical book. I divine there are many students scattered up and down the lines in an exactly similar position, and there are many possibly crippled for life, as well as those who have made the great sacrifice, and for whom concessions have come too late; but I would like to ask your readers if they think this right. Are these first-year students I speak of to have no consideration whatsoever? Are they to remain in the ranks till they are all killed or crippled, or for the duration of the war? I plead for nothing but fair play all round. If this latest army concession is considered to be so, then I have nothing to complain about.—I am, etc.,

December 8th.

"AUX ABSENTS LES OS."

THE REMUNERATION OF RURAL PRACTITIONERS UNDER THE INSURANCE ACTS.

SIR,—Now that most of the County Insurance Committees have completed the final settlement for the year 1916 with the panel practitioners, I have been watching for criticisms on it.

I live in Somerset and also work on a fringe of Wiltshire, and have a panel in both counties, but the Wilts one is very small, and I am practically in touch with all my patients on my panel. On analysing my list for last year I find it was inflated about 2.5 per cent., and I had 11.5 per cent. deducted from the guaranteed 9s. per head, leaving me 9 per cent. short in payment of work actually done. In Somerset the insurance officials had a scrutiny of my list in the middle of the year, and the deductions omitted by them I made good. In the statement of the final settlement I have 6.20 per cent. of the average of the numbers agreed on each quarter deducted, and on this reduced number I only received 7s. 8½d. a head; calculated on the numbers agreed on in the quarterly lists it only amounts to 7s. 2½d., or 1s. 9½d. less than the agreed sum. Would any other body of Government officials or any trade union continue to work under such conditions?

There is another aspect of this question which affects the position of the rural practitioner. Before the war a large number of the young people of the working classes living in the country, being dissatisfied with their life and

work had migrated into the towns, leaving our panels with an abnormal proportion of older patients. The town worker has many opportunities of learning different kinds of work, and goes from place to place where work is plentiful and wages good, but the agricultural labourer knows only one kind of work, and has to keep to it, and does not move about so much. It is therefore pretty certain that the panel lists are more inflated in the towns than in the country, and the 19.9 per cent. deducted from our payments in Somerset partly goes into the pockets of the town practitioners. As long as the county committees pay on a percentage basis so long will the interests of the urban and rural practitioner be antagonistic. The difference in the return for the work in the two cases has also to be considered. The town practitioner with a list of anything from one to four thousand or more patients can see twenty or more patients in an hour, using an infinitesimal quantity of petrol or none at all. We in the country may spend an hour or more in visiting one or two patients and use a gallon or more of petrol. Again, the fees for dispensing were fixed before the war, and still hold good, and the chemists who dispense for panels in the towns revise their prices every month. Who in the country can now dispense for panel patients except at a loss? We in the country are hampered with higher wages, dearer petrol, dearer drugs, and greater expenses in car repairs, and the town doctors have little or none of these expenses, for some keep no cars, and the mileage of those that do is small and is run on the best of roads. While they have the largest lists, the greatest percentage of inflation, and can do the work with the least expenditure of time and money, they not only get fully paid for all the work they are responsible for, but they get some of the fees earned by others.—I am, etc.,

Beckington, Bath, Nov. 21st.

W. G. EVANS.

"REFRESHMENT HOUSE" EXPERIMENT IN CARLISLE.

SIR,—The drink question, directly or indirectly, perhaps more than any other single factor, profoundly affects the health and well-being of the community.

I learn from Dr. Barnes's letter in your issue of October 20th that there has been a steady decrease of convictions for drunkenness in the city of Carlisle as the result of the activities of the Liquor Control Board. The various kinds of activities were specified by Dr. Barnes in a previous letter in the JOURNAL for June 9th, and would take too much space to repeat here.

Of seven items it appears to me that the reforms included in five of them could have been brought about equally as well through legislation not involving State management. The other two items may perhaps claim to have State management as their *fons et origo*. One has reference to elimination of adventitious aids to the sale of drink. One advocate of the Carlisle system, however, has stated that the motto of the Control Board seemed to be to make the public-house as "beautiful" as possible. Do not such beautiful adjuncts, then, act as "adventitious aids," and supply young people with better excuses for frequenting the public-house?

Allied to this is the encouragement of the sale of food and non-intoxicants. It appears to me that it would be Socialism carried very far and a confession of impotence for the State to become rivals on a huge scale to private caterers as the only plan for discouraging the use of intoxicants.

With regard to the other consideration—the most plausible of all the arguments for State management—namely, the abolition of direct interest in the sale of intoxicants, I will grant that its immediate effect may be calculated to decrease convictions, but at what cost? At the cost of involving our guardian State in direct responsibility for providing facilities (by the manufacture and sale of "Government ale" and other innumerable varieties and brands of intoxicating beverages) for making people drunk.

Is it right—morally right—for the State (and every citizen of us would be a party to it), by adopting or nationalizing the traffic, to make a single mother's son drunk?

It is bad enough that the State should have tolerated the traffic so long, without its further becoming directly responsible for traffic in a drink that Lord Rosebery and Mr. Lloyd George have by implication termed the country's

Fatal Allurer, Cruel Strangler, Strongest Enemy, and, as we may add, Abiding Traitor, and not only that of this country but of humanity at large.

In the moral sphere a good end never justifies evil means. If we cannot immediately abolish the traffic (though the capital of America has done this, at least for the duration of the war), let us gradually circumvent and restrict it by clean methods.

Nationalize railways, sugar, milk, and other beneficial things if you will, but do not nationalize the drink traffic any more than you would adopt gambling houses, opium dens, or brothels.—I am, etc.,

E. LLOYD OWEN, M.D., D.P.H.,

Medical Officer of Health for South Carmarvonshire.

Criccieth, Nov. 5th.

THE DISCOVERER OF THE CAUSE OF SLEEPING SICKNESS.

SIR,—Dr. Moffat's letter (November 3rd, p. 604) does not contribute anything material to our knowledge of the subject.

He thinks it amusing that I should act as Castellani's champion, seeing that in 1903 the latter acted "most unreasonably" in not allowing Sir David Bruce to tell me of the important discovery he had made. I have forgiven him for this, and, in common with Sir Patrick Manson, the late Professor Ehrlich, and others, I have endeavoured for several years to procure for Castellani justice and the due recognition of the importance of the great discovery made by him in regard to sleeping sickness.

There are several misstatements in Dr. Moffat's letter which considerably impair its value as evidence. (1) I did not in my letter claim to know the "entire history of the proceedings." (2) He states that I know "nothing whatever" in regard to the delicate negotiations and consultations which took place during the first few days after our arrival in Entebbe. That is incorrect, and he is doing Sir David Bruce, who was the head of the Commission, a disservice by even suggesting that such was the case. (3) The patient in whom Dr. Baker found trypanosomes shortly before our arrival was not suffering from sleeping sickness but from "trypanosome fever," and did not develop signs of sleeping sickness till nearly a year later. (4) Castellani's report—whether written by Sir David Bruce, as Dr. Moffat says it was, or by Castellani himself, as the latter has assured me is the case—is published by the Royal Society in Castellani's name, and is not therefore an "interim report on the work of the Commission," to quote Dr. Moffat's words; nor does the report, as he says it does, embody the results of the investigations of Castellani and of the whole Commission, for I did not participate in the work upon which the report is based.

Dr. Moffat's statements concerning Castellani's attitude towards the streptococcus and the trypanosome are at variance with the facts as published in Castellani's report, the last paragraph of which I reproduced in my previous letter. That Castellani did attribute great importance to his discovery of the trypanosome in sleeping sickness is, I maintain, proved by his very attitude, which Dr. Moffat calls most unreasonable, inasmuch as he would only reveal it on condition that I was not told at the time.

In conclusion, the discovery of the cause of sleeping sickness, like most important discoveries, is the outcome of the investigations of several observers. The names to be mentioned in connexion with it are, in chronological order, Forde, Dutton, Castellani, and Bruce and Nabarro, but by far the most important share of the credit must be given to Castellani. Sir David Bruce, in the paragraph in the Further Report on Sleeping Sickness in Uganda, p. 5, which I have quoted on a previous occasion, wrote:

This most interesting discovery of Dr. Castellani's [namely, of the presence of trypanosomes in the cerebro-spinal fluid of sleeping sickness patients], which was due to his introduction of the method of centrifuging the cerebro-spinal fluid in his search for his streptococcus, has been of the utmost possible value to the present Commission. It put them at once on the right track, and led to the rapid and easy elucidation of the etiology of this hitherto mysterious disease. Without a knowledge of his observation they might have worked for months in the dark, and, in truth, they might even have returned to England still ignorant as to the true cause of the disease.

Surely no stronger evidence in support of my contention could be furnished than Bruce's own words.—I am, etc.,

London, W., Dec. 3rd.

DAVID NABARRO.

army and settled in practice in Montreal, and in the following year took the degrees of M.D., C.M. at McGill University. He was for some years surgeon of the 3rd Victoria Rifles, and saw service with that regiment during the Fenian outbreak. Shortly afterwards he was promoted to be a medical staff officer of the militia of Canada.

In 1869 Dr. Girdwood was appointed lecturer in practical chemistry in the Faculty of Medicine, McGill University; in 1872 he became professor of practical chemistry, and two years later professor of chemistry. When he retired from this chair in 1902 he was named Emeritus Professor of Chemistry. He was surgeon to the Montreal Dispensary and to the General Hospital, and later became consulting surgeon to these institutions, and to the Children's Memorial Hospital. He was also consulting physician in the x-ray department of the Royal Victoria Hospital, Montreal, and chief medical officer of the Canadian Pacific Railway. Dr. Girdwood occupied a number of other important positions, among them the presidency of the Roentgen Society of America, and the vice-presidency of the Canadian Branch of the Society of Chemical Industry. He was a Fellow of the Chemical Society and of the Chemical Institute of Great Britain. He was also one of the original Fellows of the Royal Society of Canada, which was organized in 1882.

Dr. Girdwood will be remembered as a conspicuous figure among the scientific men of Canada during the last quarter of the nineteenth century—an example of the all-round scientist that will become rarer in this age of specialization; for, though fundamentally a chemist, he had a sound knowledge of medicine, surgery, medical jurisprudence, botany, physics, and microscopical technique, including photomicrography. The Rodgers and Girdwood method of detecting strychnine was devised by Dr. Girdwood and Dr. Rodgers of London, and it was Dr. Girdwood also who first applied reagents for the detection of forgeries, counterfeits, and the identification of handwriting. He was one of the first to apply the stereoscopic principles to x-ray prints.

By the death of Dr. JAMES HOLMES MORRISON the British Medical Association has lost an old and loyal member. Dr. Morrison was a native of Dunning, a village in Perthshire, where he was born seventy-five years ago. He took the diplomas of L.F.P.S.Glas. in 1865 and L.R.C.P.Edin. in 1866, proceeded to the degree of M.D. in 1869, and subsequently obtained the Fellowship of the Royal College of Surgeons of Edinburgh in 1884. For many years he practised in Perth and at one time held many local appointments, and in addition was Surgeon-Captain of the 4th V.B. Royal Highlanders. Dr. Morrison joined the British Medical Association in 1875 and was one of the prime movers in the formation of the Perthshire Branch in 1888, when the members of the old Perthshire Medical Association petitioned the Council to be recognized as a Branch of the British Medical Association. He was a regular attendant at the annual meetings of the Association. Some years ago he removed to practise in London, afterwards settling in Dover, where he actively worked down to the time of his death. He was a well known freemason, a captain of the National Reserves at Dover, and took a keen interest in all public affairs.

LIEUT.-COLONEL WILLIAM DICK, R.A.M.C.(retired), died very suddenly at Ealing on November 12th. He was born on April 6th, 1856, educated at Edinburgh University, where he graduated M.B. and C.M. with honours in 1877, also taking the diploma of L.R.C.P.Edin. in the same year, and subsequently studied in Paris. He also took the F.R.C.S.Edin. in 1884, and the D.P.H.Victoria in 1889. Entering the army as surgeon on February 4th, 1882, he became surgeon-major on February 4th, 1894, and lieutenant-colonel on February 4th, 1902, retiring on April 6th, 1911. He served in the Sudan campaign of 1885, being present at the battle of Abu Klea, and receiving the medal and star. For nine years he was assistant professor and afterwards professor of military surgery at the Army Medical School, Netley, and was in charge of the surgical division of the Royal Victoria Hospital, Netley, during the South African war. Last year he served for some time as president of the Recruiting Medical Board at Bury, till failing health caused him to resign.

DR. T. S. SPROULE, who died suddenly at Markdale, Ontario, on November 10th, was a member of the Canadian Senate, and from November, 1911, to December, 1915, Speaker of the House of Commons. He was generally recognized as leader of the Orange Party, and was Grand Master of the Loyal Orange Association of British America. He was of Irish parentage, and was born on October 25th, 1843, in the province of Ontario. Dr. Sproule graduated in medicine from the Victoria University, Toronto, in 1868, and, after practising for a few years in other places, finally settled at Markdale.

Medical News.

THE library and offices of the Royal Society of Medicine will be closed on December 24th, 25th, and 26th.

THE Home Secretary has appointed Dr. A. H. Norris, Chief Inspector of Reformatory and Industrial Schools, to be chairman of the Juvenile Organizations Committee.

THE Royal Dental Hospital has received a donation of 100 guineas from Messrs. Barnato Brothers in memory of the late Mrs. Kate Joel.

AT University College, Gower Street, on Tuesday next, at 5.15 p.m., Major Sir Filippo de Filippi, K.C.I.E., will deliver a public lecture, illustrated by lantern slides, on the sanitary services of the Italian army.

THE Minister of Pensions has appointed Captain Herbert Lund, Senior Surgeon to the Salford Royal Hospital, and Dr. J. H. Taylor (Salford) to be medical referees for the Manchester and Salford districts respectively.

AT the meeting of the Royal Statistical Society to be held on December 18th at 5.15 p.m., at the Surveyors' Institution, 12, Great George Street, S.W., Sir R. Henry Rew will read a paper on the prospects of the world's food supplies after the war.

THE Vice-Chancellor of the University of Cambridge has received from Mrs. King, of Worthing, an offer of £1,000 5 per cent. war stock for the purpose of founding in the university a scholarship for research work on fevers, in memory of her daughter, a member of a voluntary aid detachment, who died of cerebro-spinal meningitis while on active service.

AT the last meeting of the Royal Microscopical Society a report was presented on biological work (with slides) compiled from letters received from Dr. A. E. Lechmere, lecturer in mycology in the University of Bristol, and Mr. Michael S. Pease, B.A.Cantab., both of whom are interned in Ruhleben camp.

AMONG the lectures to be given at the Royal Institution after Christmas are three by Dr. Arthur Keith, Fullerton Professor of Physiology, on the problems of British anthropology; and two by Dr. Leonard Hill, one on the stifling of children's health, and the other on the climatic adaptation of black and white men.

THE Abdulla Company, makers of cigarettes, has again this year produced a war almanac and presented 20,000 copies for sale for the benefit of the British Red Cross Society (1s., post free 1s. 4d.). It consists of a sheet for each month, with an illustration; half of the illustrations are well printed in colours. They all refer to athletics or outdoor sports. Mr. Lionel Edwards has two striking coloured drawings of hunting and polo respectively; Mr. Padday, of yachting, and Mr. Hatherell, a black-and-white sketch of lawn tennis, which gracefully recalls days before the war.

A MEETING of the West London Medico-Chirurgical Society was held at the West London Hospital on December 7th, Dr. A. J. Rice-Oxley in the chair, when papers were read on (1) methods of detecting simulated deafness, by Mr. Richard Lake, (2) methods of detecting simulated blindness, by Mr. Percy Dunn. An interesting discussion followed, members of the R.A.M.C. present stating that these forms of malingering were very uncommon in the British army. The meeting was largely attended, some sixty members and visitors being present.

AN Imperial Decree was issued on June 1st, 1917, constituting a Ministry of Public Health and Social Welfare for Austria. It is to supervise the care of war invalids, to combat war diseases, and to centralize pre-existing, unco-ordinated departments of public health and sociology. It is to have the care also of the dependants of fallen soldiers, infant welfare, housing, and insurance. Though the

medical profession is to be liberally represented, the first Minister, Dr. Baernreither, is not a medical man. One of the most important problems to be solved by the new Ministry is the future of the numerous war hospitals, which have cost much labour and money.

A NEW order regulating the supply and consumption of bread was issued in France on December 5th. Three categories of consumers are recognized. In the first category are included manual workers in heavy trades, agricultural workers, and persons of very small means; males over 16 will be entitled to 600 grams of bread a day (21 oz.), and females over the same age to 500 grams (17½ oz.). In the second category, in which males will be entitled to 400 grams (14 oz.) and females to 300 grams (10½ oz.), are included workers in light trades and persons of small means. Persons in the third category, which includes all other men and women, and children under 16, are entitled to 200 grams a day (7 oz.). The maximum allowance of 600 grams is equal to about 9½ lb. a week, and thus more than a pound higher than the British maximum. The order only applies in certain districts, but in them bread cards, which will be personal and non-transferable, will be issued. The card will entitle the holder to a book of tickets sufficient for a month. Each ticket will entitle the holder to purchase 100 grams of bread. If preferred, a bread ticket may be used to obtain an equivalent amount of flour. There is no exception on the score of health.

WE referred three weeks ago to the proceedings taken by the police against Edward Yeates, F.R.C.S.I., on the charge of wearing military uniform without lawful authority. It was explained that he had been a medical officer in the New Zealand Expeditionary Force and that he denied the validity of a notification in the *New Zealand Gazette* stating that his appointment had been cancelled at his own request. The case was resumed on November 26th, when General G. S. Richardson, commanding the New Zealand forces in the United Kingdom, said that he had nothing to do with the prosecution, which arose out of a dispute with the New Zealand Defence Department, the defendant taking the view that if he discontinued wearing uniform he would prejudice his claim for redress. The magistrate at Bow Street, in giving his decision on December 5th, held that he was bound by the notification in the *New Zealand Gazette*, and asked the defendant to give an undertaking that he would no longer wear uniform. This the defendant declined to do, having engaged for the whole period of the war. The magistrate said that, while recognizing that this was not an instance of an impostor wearing uniform without authority and also the defendant's past services, he must impose a fine of twenty-five guineas and ten guineas costs, or in default imprisonment for thirty-six days. We are informed that the defendant on December 12th gave notice of appeal.

Letters, Notes, and Answers.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology*, Westrand, London; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

S. asks for experiences in the use of cuprase in carcinoma of the stomach, the manner of its use, and the precautions which should be taken.

LETTERS, NOTES, ETC.

THE Court of Criminal appeal, on December 10th and 11th, heard the appeals of Dr. G. H. Bishop and B. G. Grantway against their conviction at the Central Criminal Court of being concerned in a conspiracy to defeat the provisions of

the Military Service Acts by enabling persons liable to military service to avoid that liability. The appeals were dismissed.

"COLLOSOL COCAINE."

MR. L. STROUD (Crookes Collosols, Ltd.) writes: On p. 744 of your issue of December 1st you publish a letter from the Secretary, Medical Research Committee, with reference to the above preparation, which infers that my letter appearing in your issue of November 24th may "be misunderstood as indicating that the Medical Research Committee or any members of their staff undertake the examination of proprietary remedies at the request of the makers." No reason is given for such inference, nor can any such inference be read into my remarks. As a fact the examination was undertaken at the instigation of Dr. Dale, whose request for samples and information to assist him was conveyed in a letter addressed by Dr. Dale to me personally.

The distinction between the undertaking of the examination of "proprietary" remedies at the request of the makers and at the request of Dr. Dale may be of import, but the following comment, indicating that Crookes Collosols, Limited, used information of a confidential nature "to publish their own statement in such a manner that any part of it could even mistakenly be attributed to" Dr. Dale, contains an unwarranted imputation, and also assumes an ambiguity which is inconsistent with phraseological interpretation. Our sole object in writing the letter you published on November 24th was to take the earliest opportunity of rectifying an error into which we had been led, and we trust that you will allow us space to make public all errors which bacteriological or clinical test prove to have been made in mere laboratory experiment and preparation. May we take this opportunity of stating that clinical tests by eminent authorities show that collosol quinine has no effect upon the parasite of malaria? Other failures we shall readily report, but no evidence has been supplied us yet to override the published reports on collosol cocaine by Professors Hewlett and Simpson and Dr. John Eyre, nor the reports received on clinical results.

Since the secretary of the Medical Research Committee refers your readers to the article by Drs. Barger and Dale and Miss Durham on collosol cocaine which appeared in the *Lancet* on December 1st, I would add that a reply has been sent to that journal.

A BOGUS DOCTOR.

WALTER HENRY RANKIN was sentenced by the Recorder, at the Central Criminal Court, on December 11th, to eighteen months' hard labour on the charge of obtaining £10 16s. by false pretences from Dr. Duncan of Homerton, and of causing false entries to be made in the register of deaths. The prisoner, who held no medical qualifications, had posed as a medical man, and in that capacity practised for a period as locum tenent to a doctor in the North of London. He subsequently set up in practice on his own account. On his arrest he was found to be in possession of two forged medical diplomas. The prisoner was stated to have acted several times as ship's surgeon on liners under the pretence that he was a Canadian medical man.

CONFIRMATION OF A RADIOGRAPHIC DIAGNOSIS.

MR. GEORGE GUNN, M.D., F.R.C.S.E. (Neston, Cheshire), writes: A man, aged 65, has had trouble at the root of the right lung for some time, considered to be due to fibroid tuberculous growth, though frequent examinations of the sputum were always negative. Dr. Thurstan Holland of Liverpool, who was asked to take a radiograph of the chest, reported that there was a very definite shadow around the root of the lung, spreading upwards along the main bronchus of the upper lobe. From the position, outline, and density of this shadow Dr. Holland came to the conclusion that there was a neoplasm present. A fortnight ago the patient had a violent attack of coughing and brought up a small hard mass about the size of a kidney bean. The Clinical Research Association report: "This is a portion of a new growth having the structure of carcinoma. It is composed of branching epithelial ingrowths and papillary outgrowths; it looks as if it must have originated in squamous epithelium."

VINCENT'S ANGINA AMONG THE TROOPS IN FRANCE.

A Correction.

WE regret that, owing to a clerical error, the name of the writer of the article on this subject (BRITISH MEDICAL JOURNAL, November 24th, p. 685) was incorrectly printed. The author is Captain R. C. Douty, R.A.M.C.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under
Each additional line
A whole column
A page

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

An Address

ON

SOME POINTS ARISING IN NERVE INJURIES.

BY

H. S. SOUTTAR, B.M., M.Ch.Oxon., F.R.C.S. Eng.,

TEMPORARY MAJOR R.A.M.C.; SENIOR SURGEON, BRITISH RED CROSS HOSPITAL, NETLEY; ASSISTANT SURGEON, LONDON AND WEST LONDON HOSPITALS.

THERE are few more striking features of the surgery of the present war than the number of nerve injuries which occur. To neurologists this should not have come as a surprise, for we owe a great part of our knowledge of the injuries of nerves to the classical work of Head and Sherren, much of which was carried out at Netley on cases from the South African war. But to many of our profession these injuries open up a field with which they were previously almost entirely unacquainted, which they had always relegated to the specialist physician or to the surgeon with an interest in that direction. Amongst the latter I must class myself, for it was my good fortune to come under the influence of Henry Head and to learn from him something of the fascination of the subject and of its great practical importance. At the present time this can scarcely be exaggerated, and I venture to think there is no subject about which it is more essential that we should all have a practical working knowledge. Before the war these cases were by no means uncommon, but they were largely overlooked. To-day they are numerous, they are sure to fall into the hands of all of us, and upon our personal skill the whole future of the individual may depend.

I propose to keep entirely to the practical aspect of the subject and to avoid all theoretical considerations. In a field so recently extended there is obviously room for wide difference of experience, and you may find that what I have to say often appears to be at variance with the expressed views of others. My own experience is founded upon the observation of some two hundred cases at Netley Red Cross Hospital, in addition to a large number seen before the war, and it seems better that I should give you a clear picture of the views held by my colleagues and myself than that I should invite confusion by attempting to harmonize these with views of which you may read elsewhere.

THE INJURY PRIMARY.

In every case that we have so far seen the injury to the nerve has appeared to us to be primary—that is to say, to be either the direct and immediate result of the wound, or of some supervening condition such as an aneurysm, or of some necessary surgical interference. In no case have we been able to discover evidence of a steadily increasing block, the result of strangulation of an uninjured nerve by fibrous tissue or callus, and we are driven to the conclusion that the very wide acceptance which has been given to this idea is the result of errors of observation. It is by no means easy for the surgeon to recognize with certainty a nerve injury in a man recently wounded, and it is quite unnecessary that he should do so until a later stage. But I have had opportunities of seeing wounds at every stage, and I am strongly of opinion that in the vast majority of cases the nerve is implicated in the primary wound.

This view is borne out by the conditions which are later found on exploration, where one almost always finds a gross injury to the nerve. The nerve may be totally severed, with the formation of end bulbs, or a portion only may be replaced by dense fibrous tissue. But in the latter case careful examination will show that some fibres at least were totally severed. The fact that complete spontaneous recovery may sometimes occur is readily explained when we recollect that one-third of the fibres of any nerve may in general be destroyed, without any permanent loss of function.

The injury being primary, it is possible to diagnose the condition at an early stage and to institute at once suitable treatment. As a result contractures can be prevented, muscles can be kept in good condition, joints can be kept free, and the whole limb can be brought to such a point that when the time does come for the nerve to regenerate,

whether by itself or with the assistance of the surgeon, it can do so under perfect conditions and with the best possible prospect of success. Of this success the foundation is an early diagnosis, and it is to this that I would next direct your attention.

DIAGNOSTIC FEATURES.

The features upon which we depend may be grouped under four headings—sensory, trophic, motor, and electrical—and these we must consider separately. In each group the changes which occur are immensely complex and require prolonged study for their proper appreciation. But all that need be recognized for the purpose of diagnosis is extremely simple and can be grasped by a little observation.

A. Sensory.

To investigate the sensory changes we only require a pin and a small piece of cotton-wool, or preferably a small soft brush. It is well to start with the brush, as the patient may regard the pin with suspicion, but in most cases the outline of loss to the gentle prick or stroke of a pin will be the better defined. It will be a little smaller than the area of loss to touch, and both will follow the whole or a portion of the cutaneous distribution of the nerve. Occasionally we may find that the area, instead of being anaesthetic, is exquisitely sensitive, and that the lightest stroke of a pin is intolerable. This indicates an injury to the nerve which has not been sufficient to destroy its conductivity, but has set up an interstitial neuritis. Such conditions may be extremely difficult to treat.

The area supplied by the ulnar is very constant, including the little and half the ring fingers, and the ulnar border of the hand. The median area is sometimes very small, and may be limited to the index and middle fingers, but it usually extends on to the corresponding portion of the palm and base of the thumb, while it always includes the dorsum of the two distal segments of the two fingers mentioned. The musculo-spiral area is a minute one on the back of the hand at the base of the thumb, for the external cutaneous branches of this nerve almost always escape.

In the leg the external popliteal area includes the dorsum of the foot and extends up the outer side of the leg for about two-thirds of the distance to the knee. The internal popliteal supplies the sole of the foot and the heel. If the sciatic trunk is injured the calf may also be anaesthetic.

A knowledge of these few areas is sufficient for at least 90 per cent. of the cases which arise, remembering that each individual varies. At each examination the area of sensory change must be mapped out with the most painstaking accuracy, for it is upon the progress of these changes that the whole prognosis and treatment of the case may turn. Accurate charts must be kept and checked every few weeks, for though the diagnosis of a nerve injury may be rapid and easy the discovery of its degree and the proof of its recovery are difficult and laborious.

B. Trophic.

Trophic changes occur in the cutaneous tissues of the same area, but they are far more marked in partial and irritative lesions than in those where division of the nerve is complete. The most striking feature is a glossiness of the skin, with disappearance of the normal folds and ridges, the part becoming, as Head remarks, "expressionless." The skin may be very dry and covered with a branny desquamation, mapping out the area, but sometimes sweating is increased, and the beads of sweat on the glossy skin give a very striking appearance. In other cases the whole surface is sodden and offensive, and is covered by a thick layer of cutaneous debris.

Vascular changes are very evident, and the skin is cyanosed or deep red in colour. The appearance suggests a feeble resistance to trauma, but actual ulceration rarely occurs except as the result of direct injury, such as an unnoticed burn or the friction of a boot. Such lesions heal slowly if protected, but in the foot the skin around an ulcer may become so thickened that healing is very tedious.

The deeper tissues share in the general atrophy, and the fingers become slender and shrunken, and even the bones lose their lime salts.

* Read to the Southern Branch of the British Medical Association, November, 1917.

These trophic changes are always present in some degree, but they are only really striking in partial and irritative lesions, where they may be accompanied by excruciating pain of an intense burning nature, and a tenderness so severe that the slightest touch is intolerable.

C. Motor.

On the motor side there will be diminution or total loss of voluntary power in the muscles supplied by the nerve, but it is often by no means easy to demonstrate clearly what muscles are involved. On the one hand, the action of paralysed muscles may be imitated by means of other groups: on the other hand, the pain of a fracture, or some other cause, may render totally inactive a group of muscles which are really intact. Thus, in a complete lesion of the musculo-spiral the whole of the extensor muscles of the forearm are paralysed, but extension of the two interphalangeal joints of the fingers can be carried out perfectly by means of the lumbricals. In the same lesion the grasp is very weak, the reason being that for a proper grasp extension of the wrist is essential. From the first circumstance it is common to see lesions of this nerve overlooked, while from the second I have actually seen them diagnosed as cases of median paralysis.

In the case of each nerve there are certain critical movements familiarity with which is important. The musculo-spiral can alone produce extension of the wrist and of the proximal joints of the fingers. Only the median can flex the index finger, and only the ulnar the little finger. Lesions of these two nerves in the forearm may, however, cause confusion, as it is not always easy to unravel the intrinsic muscles of the hand. The median alone can produce opposition of the thumb, with the rotation of that digit which this movement involves. The ulnar supplies the short but thick adductors of the thumb, and by means of the interossei can approximate and spread the extended fingers.

In the leg matters are far more simple, for the external popliteal elevates and everts the foot, whilst the internal popliteal depresses it. Errors are only likely to arise here from a contracture of the calf which interferes with the action of one or the other group of muscles, or from the possible flexor action of the peronei.

In any case of doubt the best plan is to grasp the suspected muscle and to actually feel whether or not it contracts with voluntary effort, though even here the contraction of underlying groups may be very deceptive.

The attitude of the affected limb is often characteristic, but I can only refer to the partial claw hand of ulnar paralysis affecting the little and ring fingers, and of median paralysis affecting the index; to the drop-wrist and intorted thumb of musculo-spiral lesions, and to the drop-foot and steppage gait of lesions of the external popliteal.

D. Electrical.

The electrical reactions as carried out by an expert are complex, but for most purposes they may be reduced to very simple proportions. All that is required is a small induction coil and a group of cells, or any other source of faradic and galvanic currents, with some means of adjusting them. The limb is first thoroughly soaked with warm water, and a large pad connected with one pole is placed in contact with some neutral point. A small pad connected with the other pole is used to investigate the action of each separate muscle group. The normal muscles give a quick response to each form of current, far quicker than any voluntary contraction, the response being most easily obtained at the motor points, near the entry of the nerve. If a motor nerve has been divided, the reactions of the muscles will not at first be altered, but after ten days, the nerve fibres in the muscle having degenerated, the reaction of degeneration will occur. In this condition there is no response at all to faradism, whilst to galvanism the muscle responds with a characteristic slow undulatory contraction, like the slow movement of a worm. The motor points have lost their value, and the muscle responds best to a longitudinal current, along the direction of its fibres. As recovery occurs this contraction quickens, and this is one of the first phenomena observed. It ultimately becomes normal, but it is only after the return of voluntary power that the response to faradism returns.

These simple details are all that are required for the diagnosis of any ordinary case of nerve injury. To carry them out accurately is tedious and laborious, but it is essential for success. The expert will, of course, learn to tell at a glance which nerve is affected, but only by the most painstaking work will he be able to tell the exact condition which is present, or to discover the appropriate treatment. The investigation must be carried out not once but many times if the course of the case is to be followed with any approach to accuracy. But if sufficient trouble is taken we can by these means trace exactly the recovery of a case, state definitely the further period required, and modify the treatment to the precise conditions which are present.

TREATMENT.

From the point of view of the ultimate utility of the limb, a nerve injury overshadows in importance any other damage that may have occurred. A badly united fracture or a clumsy scar are mere trifles compared with an unhealed nerve. It is therefore essential that the treatment of the case should be directed to the repair of the nerve from the earliest moment at which the case is seen. I would impress upon you that operation is only an incident in the treatment, and that it must be preceded and followed by months of work, of which the technique is even more elaborate than that of the theatre. It is so much the custom to divide up the subject into diagnosis, operation, after-treatment, that one is apt to forget that it is just as easy before operation as after to maintain the nutrition of the muscles and the skin, and to preserve the flexibility of joints, and that it may be necessary to go on doing this for months or even years before the nerve awakens from its long sleep and deigns to take up the work itself. I shall therefore first speak of the treatment of the limb, and afterwards turn to the repair of the nerve.

When the limb is first seen there is probably a large septic wound with a fracture, and these must of course at first be the principal considerations. But even here it is easy so to arrange splints that paralysed muscles are relaxed, and that if joints should become stiff they will do so in useful positions. The way not to do it is well exemplified by a wrist sling in the case of a fractured humerus with an injured musculo-spiral, and by a Mitteldorpf's triangle in a high fracture of the same bone. Yet one has often seen both.

Our physical treatment is carried out as a definite routine in a special department under the charge of Captain Twining, R.A.M.C., to whose care its success is largely due. It is grouped in four sections—massage, exercises, whirlpool baths, and electrical—each with its appropriate staff, and when their treatment is in full swing most patients will pay a daily visit to each section.

Massage.

The first treatment which can be adopted is massage, and to it must be given the premier place throughout. It should be started at the earliest possible moment, and splints should be so arranged that as much as possible of the limb can be reached. But even if only a very small area is available it should not be neglected. Massage provides a gentle exercise for the muscles; it gets rid of their waste products, it keeps the skin in condition, and it maintains the circulation and the general nutrition of the limb. The masseuse can preserve the mobility of the joints, and prevent the formation of adhesions, and indeed can in many ways neutralize the results of prolonged inactivity.

Exercises.

When gross damage to the limb has been more or less repaired, wounds healed and bones united, movements, active and passive, on a larger scale may be attempted. For this purpose many ingenious machines have been devised, following the ideas of Zander. The central idea in the best of these is that the patient does gentle work on a machine which includes either a pendulum or a flywheel, the inertia of which always tends to carry the movement a little further. By this means any adhesions which may have formed in joints, or between muscles and tendons, can be gradually broken down and a wide range of movement obtained, whilst the non-paralysed muscles are fully exercised, and regain their normal power.

Whirlpool Baths.

A new form of treatment has lately come into favour in the form of the whirlpool bath. The idea started in France as the "eau courante," but it has been greatly developed in England. The principle is that the limb is surrounded by a stream of rapidly-moving water at as high a temperature as can be comfortably borne, about 110° F. The result is a rapid absorption of heat by the limb, the blood flow in which is in consequence greatly accelerated, whilst at the same time it is subjected to a continuous gentle massage by the moving water. The sensations of the patient are very pleasant, pain is often relieved, and the feeling of stiffness rapidly disappears. The limb is kept in the bath for twenty minutes, at the end of which time it will be found that the skin and muscles have become soft and supple, and that a remarkable relaxation of contracted muscles and ligaments has taken place. Both to appearance and manipulation the limb has improved to a degree that is quite astonishing, and the work of the masseuse is facilitated to an extent that can only be appreciated by experience. We find, in fact, that twenty minutes in the whirlpool bath, followed by ten minutes' massage, is better in its results than thirty minutes devoted to the older form of treatment. The economy in skilled work can be seen at a glance, and, as a matter of fact, the capacity of our massage department has by this simple means been trebled.

Electrical.

The last section of our physical department is the electrical, and I must confess that my ideas as to the value of this method have been revolutionized. We now regard it as at least equal in value to the methods which I have already mentioned, and as having peculiar possibilities of its own. We use two forms of current—galvanic and sinusoidal. The latter is used through the medium of baths, and probably acts chiefly on the vascular channels, for it is never used in sufficient strength to provoke contraction of muscle. The paralysed muscles will, of course, only respond to the galvanic stimulus. This is arranged by means of a metronome to come at regular intervals of two or three seconds, or the small moist pad which forms the electrode is slowly stroked up and down the limb, the muscles responding in turn by a gentle wave of contraction. In many cases the patient is left to do this for himself, which not only releases the nurse but also stimulates the patient's interest in the progress of his own limb, a very important factor in success.

In the intervals between treatment every precaution must be taken to keep the limb warm, protect atrophic skin from injury, to keep paralysed muscles relaxed, and to prevent the development of contractures. A stretched muscle will never recover its function, and in such lesions as drop-wrist and drop-foot an apparatus must be worn which will over-correct these deformities.

This may be taken as a general outline of the treatment we adopt in all cases, though of course variations are often required. We find that the combination works well, each item supplying its own special quota to the whole. The routine is less fatiguing to the staff, whilst the patient finds the passage from one department to another less irksome than the devotion of a longer time to one form of treatment. In fact he comes to regard his treatment as a pleasant occupation for a good part of the day, an important consideration when it must extend over many months before recovery can be expected. The improvement in the limbs is most striking, and we pride ourselves on their almost normal appearance. The skin is supple, the muscles well nourished, and the joints free. The result is the comfort of the patient and the rapid recovery of the nerve.

Operations.

I have left till the last the consideration of operative treatment, partly because I wished to lay stress upon other aspects of the subject and partly because the technique of these operations is very special and should only be attempted in centres where there is an opportunity of gaining a wide experience of the peculiar difficulties involved. The first essential to success is an accurate and intimate knowledge of anatomy, for without it one may wander hopelessly in the masses of scar tissue which all but obliterate the landmarks. Of course, no operation can be undertaken until all risk of sepsis has gone—that is to say, until the wound has been soundly healed for

at least six weeks, or, where bone is involved, for a still longer period.

The suture of a divided nerve where the gap is small and there are no complications is simplicity itself. The nerve is completely freed for some inches above and below the point of injury, where it will be found to be replaced by a mass of fibrous tissue, possibly containing a more or less complete end bulb. The nerve itself must never be handled, but the fibrous part can be held in forceps while a fine catgut suture is passed through the nerve above and below the point of injury. The damaged portion is then resected until all fibrous tissue has been removed and nerve fibres can be clearly seen in both the cut ends. The catgut suture is then drawn tight and the gap closed without any handling of the nerve whatever. A few additional sutures may be required in the larger nerves to close the sheath, but it is upon the first suture that we depend for strength. I am quite unable to see that it can do any harm. It merely separates the fibres of the nerve without cutting them, while it gives a firm and substantial union between the ends.

If there were no further difficulties in nerve suture it would be one of the simplest of operations. Unfortunately, such simple cases rarely occur. In the first place, it may be extremely difficult to find the nerve ends at all, and it may be necessary to start at quite a distant point in order to discover them. In fact, I always begin now with a long incision, and only approach the damaged part when I have isolated the nerve on both sides. In the case of a nerve whose course is so complex as that of the musculo-spiral the difficulties of such a proceeding will be obvious.

The ends being found and cleared, there may be so large a gap that it can only be bridged by artifice. Where it is physically possible the ends are brought together and united by direct suture, for no other method can give such certain results. In most cases it can be accomplished by very wide freeing of the nerve, the vascular supply of which is always ample to allow of this, and by placing the limb in a suitable position. Thus, in the case of the sciatic it is possible to obtain direct suture after the resection of three inches, if the knee is flexed and the hip extended. In one case, where three inches of both median and ulnar had been blown away in the right upper arm, I resected that length of the humerus with complete success, both nerves recovering.

Where there is a large gap there is usually a large end bulb on the proximal end. In this case one may take advantage of a flap operation which I devised to meet the difficulty, and from which we have obtained excellent results. A flap is turned down as far as the bulb, which forms a sort of hinge. The terminal half of the bulb is now amputated, and the raw surface, on which the majority of the fibres must appear cut across, is folded over itself and sutured. In this way the living fibres are preserved to almost their extreme point, and a living scaffold is provided for their downgrowth, which still retains its blood supply. The results of this method have been surprisingly good, and the recovery of one case was, in fact, the most rapid in our records.

In other cases the only way to bridge the gap is by the introduction of a graft, and for this the radial nerve is useful. It is of small diameter, but it can usually be doubled, whilst its removal leaves, as a rule, no disability. I have never used any other material, such as catgut or animal nerve, and I am doubtful as to their utility. Autogenous grafts are undoubtedly preferable.

Perhaps the most attractive of all methods, in a case otherwise impossible, is cross-grafting. This has given brilliant results in animal experiments, and I can see no reason for the wholesale condemnation to which it has been subjected. It can certainly be done without permanent damage to the healthy nerve, for it is possible to divide one-third of the fibres of the median, for example, without any permanent disability whatever. I have done it on three occasions for the benefit of the musculo-spiral, and though they are somewhat recent cases I feel confident from their progress that they will be successful. At the same time it is a method which must at present be regarded with great reserve and only adopted in very special cases.

CONCLUSION.

I trust that in my attempt to give a clear outline of the subject the dogmatic manner in which I have stated my

case may be pardoned. To have adopted any other attitude in such a short communication would have been to invite confusion. My object was not to assert the correctness of any particular views, but to bring home to you the importance of the subject to all of us. I hope you will now agree with me that every medical man, even if he has no time to devote to their study, should at least be alive to the importance of nerve injuries and to the possibilities of their cure.

"MYALGIA": ITS DIAGNOSIS IN FORWARD AREAS.

BY CAPTAIN FRANCIS B. CHAVASSE, M.C. R.A.M.C.,
B.A. OXON., M.R.C.S., L.R.C.P.

Introductory.

THE term "myalgia," originally introduced in order to rescue a certain class of case from the heading "rheumatism," shows a tendency under the conditions of diagnosis which obtain in forward areas to be expanded so as to hold almost as much as the term "rheumatism" itself.

In view of the importance of accurate diagnosis in these cases, both from the point of view of treatment and from the point of view of economy in man power—that a man may be allocated early to work suited to his physical powers—inquiry was made to ascertain the extent, and the directions, in which it might be possible to improve the diagnosis "myalgia" (as generally made) by the application of simple and rapid criteria suitable to the difficulties which attend diagnosis in the front line.

And further, inquiry was made into the leading symptoms of myalgia as seen by the regimental medical officer, in order to provide a basis on which, after the exclusion of conditions likely to be confounded with it, the diagnosis "myalgia" might rapidly and reasonably be made, and (an important point) the severity of the case judged.

The importance of accurate diagnosis at the outset of a patient's journey towards rear areas is enhanced by the great weight which any diagnosis once made carries with it; and the reluctance of a medical officer in a rear area to change the diagnosis—forgetful of the fact that it may have been made in a shell hole. And another reason why the diagnosis myalgia is seldom corrected is that myalgia, by reason of the intangibility of its symptoms and the opportunity it affords to malingerers, has got a bad name, and is generally regarded as a nuisance rather than as a problem.

The observations on account of which follows were conducted at a field ambulance over a period of three months, and with a front line battalion over a period of twelve months. A few cases necessary to complete the series were seen at a casualty clearing station.

I. Differential Diagnosis.

The application of the rough and rapid diagnostic criteria shown below to 200 cases reaching field ambulance and casualty clearing station diagnosed myalgia resulted in an improvement of the diagnosis in 60 cases, excluding those newly diagnosed "neuralgia," and in 108 cases including the new diagnosis neuralgia (that is, in more than one half)—as shown in the accompanying table.

Pyrexial Conditions: P.U.O., etc. (19 cases=9.5 per cent.).—In almost all cases the pyrexia was in the evening only. It is noticeable, especially in winter and when for any reason it is difficult to keep the troops warm, that a patient may have an evening temperature as high as 102° and yet be subnormal at the sick parade early next morning. Hence the pyrexial nature of the condition is easily overlooked, unless there is an unofficial evening sick parade or some such arrangement.

Post-pyrexial Conditions (19 cases=9.5 per cent.).—In the majority of cases the patient was able to state that he had been in hospital a short time previously (within five weeks) and that "it said P.U.O. on the card." Patients appear to take a most painstaking interest in their cards.) In a few cases only the pyrexial nature of the forerunning illness had to be judged by the patient's history of his symptoms—headache, sweating, etc.

The predominant features of these post-pyrexial pains are (i) that they are present in an aggravated degree when

Table showing the Result of an Attempt to Improve the Diagnosis in 200 Cases Diagnosed "Myalgia."

New Diagnosis.	Criteria Applied.	No. of Cases.
Pyrexial conditions	Pyrexia (usually evening only)	19
Post pyrexial conditions	History of "P.U.O.," or trench fever, within previous 5 weeks, with more or less continuous pain since	
Neuralgia*	Pain, aggravated when patient is lying down, warm, and perfectly still	12
Ostalgia*	Ditto. Tenderness over shins	5
Unspecified	Pain on movement. Stiffness aggravated after rest	2
Arthritis	Creaking	
Osteo-arthritis	Palpable bony deformity	3
Rheumatoid arthritis	Periarticular infiltration	6
Unspecified	—	7
Sciatica	Kernig's sign. Nerve tenderness	4
Neuralgia†	Pain, aggravated when patient is lying down, warm, and perfectly motionless	46
Muscular stiffness following considerable exertion	History	2
Gout	Joint signs	1
Muscular cramps	History	1
Total		108

* Usually accompanied by pain on movement.

† Previous history of "P.U.O." or trench fever, in 21 cases occurring from 5 weeks to 1 year previously.

the patient is warm in bed and lying motionless, and (ii) that they are referred to the shin bones in many cases, there being in a few cases actual tenderness over the subcutaneous surface of the tibia. True myalgic pains, in marked contrast to this, are absent at complete rest but aggravated after rest, until the stiffness, which has increased during rest, has worked off.

Pyrexial and post-pyrexial conditions (19 cases each) thus account for 38 of the 108 cases in which the diagnosis "myalgia" was susceptible of improvement. The importance of the alteration is seen as soon as the question of treatment is raised; the treatment of myalgia by massage, liniments, Turkish baths, etc., being definitely contraindicated in pyrexial conditions, and hardly the best for post-pyrexial neuralgia and ostalgia, in which delayed convalescence seems to be the main factor.

Arthritis (16 cases = 8 per cent.: osteo-arthritis 1.5 per cent., rheumatoid arthritis 3 per cent., unspecified 3.5 per cent.).—The joints affected were mainly knees. A few shoulders were included in the series and one hip. The preponderance of knees is probably largely due to easy diagnosis. There is no doubt that a skilled diagnostician, especially if unhampered by time, would be able to take many more cases—especially shoulders, hips, and spines—out of the myalgic abyss.

The figures are considerable enough in themselves, and become more so in view of the fact that the patients were drawn almost exclusively from what in Germany would be termed a "shock" division, and included few above 40 years of age. The arthritis figures for labour battalions and so on would naturally be very much higher.

The importance of detecting the cases is economical. No treatment for "myalgia" makes them fit for winter work in the trenches. They are a burden to field ambulances and to hospitals, and are only a paper asset to their division, but once the condition is recognized there is some chance that suitable employment may be found for the cases.

Sciatica (4 cases = 2 per cent.).—The diagnosis is important from the point of view of treatment; adequate treatment of recurring sciatica being unobtainable at a field ambulance. Occasionally the rough diagnosis "sciatica" is made where "myalgia" would be nearer the mark.

Neuralgia (46 cases = 23 per cent.).—The importance of this distinction is at present mainly scientific. Patients generally classed as myalgics fall broadly into two distinct classes. In the one class there is no pain when the

patient is warm in bed, unless he attempts to move. Rest makes him stiff. This stiffness wears off with gentle movement. There is pain, often described as acute and stabbing, on quick movement. Prolonged exertion precipitates or increases the condition. This is true myalgia. In the other class there is pain of a character which is variously described as "aching," "gnawing," and "throbbing," which is aggravated when the patient is warm in bed, and persists although he be absolutely motionless. He complains of inability to sleep; there is often considerable cutaneous hyperaesthesia. This class of case I have called "neuralgia"; it is very distinct from myalgia.

The 46 cases include 2 cases of severe neuralgia of the feet following exposure, and 5 cases more or less confined to the upper extremity, but the majority followed the usual myalgic distribution—namely, lumbo-sacral and lower extremity.

The curiosities of muscular stiffness following considerable exertion (2 cases = 1 per cent.), gout (1 case = 0.5 per cent.), and muscular cramps (1 case = 0.5 per cent.), complete the 108 cases in which, in a series of 200, the diagnosis myalgia was susceptible of improvement by the application of diagnostic criteria suitable, by reason of their simplicity, to forward areas.

II. Symptoms and Signs of Myalgia.

After the exclusion of the conditions dealt with above under the heading Differential Diagnosis there remains a residue. A number of cases with rheumatic symptoms reporting sick at the medical inspection room of a battalion were examined with a view to determining what are the leading features of myalgia (using the term in a restricted sense) as seen in forward areas. The hope was entertained that a sufficient definition of the condition might be obtained to render diagnosis more certain and rapid.

The question of *malingering* assumed considerable importance in the inquiry. Gross malingering was in my experience uncommon; but the exaggeration of symptoms was very prevalent among those who were in the habit of reporting sick. A lugubrious outlook is common among patients, due as much to their failure to rise above the misery and hardship of their surroundings as to their actual pains. Such patients whose spirit has been damped, even if not actually extinguished, form the considerable majority, I think, of the sick of the army in forward areas, and are clearly unsuited to be the media of a scientific inquiry into which symptoms enter more than physical signs. Nor, under war conditions, may much tempering of the wind be accorded to these "shorn lambs"—at the expense of their more spirited comrades.

Only patients whose mental health had not suffered too severely from the strain of war are represented in the figures which follow. Thus the inquiry was begun in 264 cases. But in 214 of these it was abandoned either owing to another diagnosis being made or owing to the vitiated mental outlook or inferior intelligence of the patient or owing to the slightness of the case. The inquiry was concluded in 50 cases which may be taken as typical of genuine uncomplicated myalgia as seen in forward areas.

The regions affected were as follows: Cervical 1, dorsal 9, intercostal 2, lumbar 36, sacral 28, shoulder 6, arm 1, elbow 1, forearm 1, wrist 0, hand 0, buttock 15; thigh—anterior 7, lateral 23, posterior 34, mesial 10; knee 31; leg—anterior 16, posterior 12, lateral 21; ankle 4, foot 6. An attempt to define more exactly the muscle groups involved by observing the effects of active and passive movement of various groups had to be abandoned owing to the claims of other work.

The distribution is usually symmetrical (36 cases) and is in the majority of cases lumbo-sacral, extending down the lower extremities for a varying distance. The lumbar and sacral pains are by no means always coexistent. In fact the general rule is for the pain to be either lumbar or sacral, the thigh pains being superadded in each case. Occasionally the pains are present in the lower extremities but absent in the lumbar and sacral regions; and the converse is common in convalescence. One case of "stiff neck" occurred in the series and two cases of pleurodynia. No case of pure acute lumbago was seen. In one case the pain was confined to the upper extremity.

Pain is absent when the patient is lying down, warm, and perfectly still (44 cases). This is a marked distinction

from pyrexial, post-pyrexial, and neuralgic conditions. In these the pain is aggravated when the patient is warm in bed.

Rest makes the patient stiffer (46 cases). This stiffness wears off on moving about gently (34). Active contraction and passive hyperextension, especially if quick, cause pain, which is described as sharp rather than dull (45). Cold and damp weather precipitates or aggravates the condition (37). Prolonged exertion (route marching with full pack, digging, etc.) have a like effect (41). Massage is painful (27 cases out of 31) but beneficial (21 cases out of 31). The condition is chronic (previous attacks in 44 cases). The site of the pain is generally identical in successive attacks (29 cases out of 44). The onset is usually sudden (35).

There appears to be no connexion between previous pyrexial attacks and myalgia. But in the case of neuralgia (see Differential Diagnosis above) there would seem to be a definite relationship. The young are not exempt (one case aged 19), but the condition is uncommon under 30 and increasingly common thereafter.

III. Definition of Myalgia.

The practical delimitation of myalgia by more accurate differential diagnosis is, perhaps, more important than its definition in words. But from the foregoing it may be said that myalgia is a chronic condition, precipitated or exacerbated by cold, damp, and fatigue, affecting groups of muscles and characterized by muscular stiffness becoming greater on resting and less with movement, and by pain, absent at complete rest, and sharp on active contraction and passive hyperextension. It is to be distinguished from neuralgia by the facts that in neuralgia the pain is aggravated when the patient is warm and motionless, and that in neuralgia hyperaesthesia of the skin is commonly present.

IV. A Method Found Useful in Forward Areas for Examining Patients Complaining of Rheumatic Pains.

The number of cases of rheumatic pains coming under the notice of the regimental medical officer is large. In my experience he is called upon to give a decision in such cases upwards of 2,000 times in the course of a year in the forward area, the same patient often, of course, reporting sick repeatedly.

Under these circumstances the plan of making a fairly complete examination at the outset and, as an aid to memory, noting the result in an alphabetical book kept for the purpose (or by hieroglyphic in the patient's pay book) has been found to meet the case. It not only saves a vast amount of time in the long run, but provides at once a diagnosis that is as accurate as possible. It prevents the sick parade from becoming a farce, and ensures that justice is done alike to the genuine case and to the "skrimshanker."

The method of examination which follows is necessarily simple and rapid, and takes more notice of symptoms than of physical signs; but it has been found useful in arriving at a fairly accurate diagnosis under conditions which make diagnosis difficult. The method is as follows:

(1) Take the temperature—evening if possible; if not, pay special attention to headache and other feverish symptoms. While taking the temperature note (2) general appearance, (3) apparent age, (4) pupils (especially for the contraction of insomnia), (5) conjunctival anaemia, (6) pulse, (7) respiration. Note also the condition of the tongue. These observations eliminate pyrexial conditions and acute illness generally.

Interrogate the patient as follows: (9) "Where do you get pain?" (10) "Where is it worst?" (11) "When do you notice the pain most?" (12) "Is there any pain when you are lying down, warm, and perfectly still?"

The answers to these questions may suggest arthritis (examine for creaking and gross joint signs); sciatica (examine for Kernig's sign and nerve tenderness); tibial ostalgia (examine for tenderness over the subcutaneous surface); or neuralgia (examine for cutaneous hyperaesthesia and inquire for history of previous pyrexia).

Then proceed: (13) "Is this your first attack?" (14) "How long have you been subject to these attacks?" (15) "What brings them on?" (16) "Do they always affect you in the same place?" (17) "What do you do

for them?" The last question aids in determining the severity of the case.

The attempt should next be made to produce pain by active and passive movement, the patient's appearance being noted the while.

Then ask: (18) "Is the pain sharp or dull?" If he has had rubbing or massage, ask: (19) "Is massage painful?" (20) "Does it do you good?" Proceed to inquire about stiffness by asking, (21) "Does rest make the stiffness greater or less?" (22) Does the stiffness get greater or less when you are up and moving about?" Conclude with some such phrase as (23) "When you move *quickly* you get a sharp stabbing pain. Can you do as much as anybody else if you go slow?"

TREATMENT OF THROMBOSIS.

BY
H. FAIRLEY MARRIS, CAPTAIN R.A.M.C.

VENOUS THROMBOSIS such as occurs in the typhoid group of fevers may be speedily aborted by the intravenous injection of sodium citrate.

During the past two years seventeen cases of venous thrombosis have been under my care, the majority having arisen during the course of an infection bacteriologically proven to be by a member of the enteric group, the remainder occurring during the course of other fevers of obscure origin.

This complication has long been recognized as prolonging convalescence and leading to permanent mischief, such as troublesome swollen limb or the formation of intractable varix.

The signs and symptoms as seen in my series may be briefly described. Rigors were noted in four of the cases. Fever was always present; pain invariably so, on two occasions being so severe that the question of intestinal perforation arose. Swelling of the limb was always present, usually appearing on the third day from onset of the other symptoms. In most of the cases the thrombus could be felt.

Among the enteric cases the distribution was as follows: Left femoral 2, right femoral 1, right and left femorals 1, left iliac 2, right and left iliacs 1.

The remaining three cases occurring during the course of other fevers were: Left femoral 2, right and left popliteals 1.

The earlier cases were treated on the usual lines—namely, locally with anodyne liniments, and internally by the liberal administration of citric acid and a milk-free diet.

The following is the first case treated by the intravenous injection of sodium citrate:

A soldier (Case 1 in the table), aged 19, admitted to hospital on the twenty-third day of his illness, which was subsequently shown to be typhoid fever. The temperature was 101° F., and the pulse 106 per minute. By the thirty-second day the temperature had regained the normal by lysis; the pulse rate, however, was still about 100 per minute.

On the thirty-fourth day the temperature rose to 100° F., and the patient complained of considerable pain in the lower part of the left abdomen. A thrombus was suspected, but nothing could be felt, and measurements round the two lower limbs at the calves gave the same result—namely, 10½ in.

By the thirty-fifth day the left leg was swollen, and on the thirty-seventh day oedema was observed in the right ankle. The swelling in both legs increased rapidly, and by the thirty-ninth day the man was in such agony and the abdomen so rigid that the possibility of an intestinal perforation was considered.

By the fortieth day the thighs resembled bolsters, and the superficial veins on the lower part of the abdomen became so conspicuous that the inferior vena cava appeared to be involved.

I thereupon resolved to try the effect of a 0.5 per cent. solution of sodium citrate in normal saline. Half a pint of this

The last question is a valuable one for testing the patient's mental outlook. It puts him on his mettle. A genuine case answers in the affirmative or with a negative that is obviously reluctant. Cases in which there is unwillingness of the spirit as well as weakness of the flesh are not ashamed to give a negative the tone of which is whining in "war-worn" cases, and impressive, indignant, or sanctimonious in patients who are knowingly exaggerating their symptoms.

If the answers seem to coincide with the definition of myalgia given above, the diagnosis is made and a note registered for future reference as to the degree of the condition, and as to the degree, if any, of exaggeration employed.

solution warmed and sterilized was slowly run into the median basilic vein of the left arm. Twelve hours later the pain had almost gone. The following day a second injection of 8 oz. was given, and by the next morning the temperature had fallen, the patient was free from pain, and the abdomen was quite soft. A speedy recovery took place.

Imperial drink was given before the first injection; thereafter this was suspended. Below are shown a few of the calf measurements taken on the days stated:

Day of Disease.	Right Calf.	Left Calf.
34th	10½ in.	10½ in.
35th	10½ "	12½ "
37th	12½ "	12½ "
40th	13½ "	13½ "
45th	12½ "	12½ "
57th	11 "	11 "
60th. Got up for first time.		
61st	10½ "	10½ "
73rd. No oedema	10½ "	10½ "
74th. Evacuated as a walking case.		

From information received it was learnt that this patient was returned to duty 104 days from the onset of his illness—that is, seventy-four days from the beginning of the thrombosis.

This result was so striking when compared with those cases I had already seen that I decided in future to treat such cases by the oral and intravenous

methods alternately. Limb measurements were taken daily. On two occasions an attempt was made to compare the coagulation time of the blood before and after the injections.

The method used was as follows: a long capillary tube was drawn out and filled with the patient's blood from a finger prick; the tube was then quickly broken into inch-long pieces. Every quarter of a minute one of these was taken and the blood expelled by blowing, until, on account of coagulation, this was no longer possible. In Case No. 4 it was found that the blood could be expelled from only eight of the tubes before the injection, whereas after the injection the blood was readily expelled from twenty-four tubes. The coagulation time of the blood had been changed from two to six minutes.

In the earlier cases the injections were followed by rigors occasionally, which occurred as early as half an hour and as late as three hours afterwards; they were never severe, and were quickly relieved by half an ounce of brandy and hot bottles. With more careful preparation of the citrate solution, using recently distilled water and efficient sterilization, the rigors have not been observed. Rigors are not infrequently observed after intravenous injections of other substances, and this is not an important point.

The following table sufficiently explains itself.

CASE 1.—A = Pain in left iliac fossa. B = Injection of 0.5 per cent. sodium citrate.

VENOUS THROMBOSIS.
Cases of the Enteric Group treated by the Intravenous Injection of 0.5 per cent. Solution of Sodium Citrate.

No.	Age.	Bacteriological Diagnosis.	Site of Thrombosis.	Onset of Thrombosis.	Subsequent Pyrexia after First Injection.	Measurements of Calf (Inches).	Convalescence.*	Treatment.	Subsequent History.
1	19	Typhoid by agglutination	R. and L. iliac, inferior vena cava	33rd day	5 days	37th day: R.12½, L.12½ 41st day: R.10½, L.10½	21 days later	40th day: 10 oz. of 0.5 % sodium citrate intravenously. 41st day: 8 oz. of 0.5 % sodium citrate intravenously. No change in diet. Imperial drink by mouth.	Evacuated to United Kingdom (walking case, no oedema) 35 days after onset of thrombosis; returned to duty 70 days after onset of thrombosis.
2	28	Typhoid; <i>B. typhosus</i> in urine	L. iliac vein	38th day	8 days	38th day: R.11½, L.13 49th day: R.11½, L.11½	19 days	38th day: 8 oz. of 0.5 % sodium citrate intravenously. Mild rigor 3 hour after injection. No change of diet; no citrates by mouth.	Evacuated to United Kingdom (walking case, no oedema) 40 days after onset of thrombosis.
3	27	Typhoid by agglutination	L. femoral	24th day	7 days	25th day: R.10½, L.12½ 44th day: R.10½, L.10½	17 days	25th day: 6 oz. of 0.5 % sodium citrate intravenously. No change in diet; no citrates by mouth. Cragulation time before injection 2 minutes; after injection 6 minutes.	Evacuated to United Kingdom (walking case, no oedema) 24 days after onset of thrombosis; returned to duty 80 days after onset of thrombosis.
4	20	Paratyphoid B bacillus in urine	L. femoral vein	22nd day	8 days	25th day: R.11, L.12½ 44th day: R.11, L.11½	23 days	26th day: 6 oz. of 0.5 % sodium citrate intravenously. Mild rigor 2 hours after injection. No change in diet; no citrates by mouth.	Mental case throughout. Evacuated to United Kingdom (sitting case, no oedema) 32 days after onset of thrombosis.
5	28	Typhoid by agglutination	L. femoral	27th day	11 days	27th day: R.11, L.11½ 49th day: R.11, L.11½	17 days	27th day: 10 oz. of 0.5 % sodium citrate intravenously. 29th day: 7½ oz. of 0.5 % sodium citrate intravenously. Each injection followed by moderately severe rigor 3 hours later. Cragulation time before injection 1½ minutes; after injection 6 minutes. No change in diet; no citrates by mouth.	Evacuated to United Kingdom (walking case, no oedema) 31 days after onset of thrombosis; returned to duty 80 days after onset of thrombosis.
6	26	Paratyphoid B by agglutination	L. femoral	43rd day	9 days	44th day: R.10½, L.12½ 54th day: R.10½, L.10½	14 days	45th day: 5 oz. of 0.5 % sodium citrate intravenously. 46th day: 5 oz. of 0.5 % sodium citrate intravenously. No change in diet; no citrates by mouth.	Evacuated to United Kingdom (walking case, no oedema) 28 days after onset of thrombosis; returned to duty 10 weeks after onset of thrombosis.
7	24	Paratyphoid B isolated from stools	R. femoral L. femoral	46th day	8 days	49th day: R.14, L.12½ 52nd day: R.15½, L.12½ 57th day: R.14½, L.12½ 69th day: R.12½, L.12½	24 days	49th day: 4 oz. of 0.5 % sodium citrate intravenously. 51st day: 10 oz. of 0.5 % sodium citrate intravenously. 55th day: 10 oz. of 0.5 % sodium citrate intravenously.	Evacuated to United Kingdom (sitting case, little oedema) 26 days after onset of thrombosis.
<i>Cases of the Enteric Group treated by the Oral Method.</i>									
8	20	Paratyphoid B isolated from stools	L. femoral	23rd day	10 days	—	19 days	10 gr. citric acid, four times a day; imperial drink ad lib.; no milk	Evacuated to United Kingdom (walking case 29 days after onset of thrombosis; returned to duty 35 days after onset of thrombosis.
9	27	Paratyphoid B isolated from blood	L. femoral	41st day	10 days	—	60 days	10 gr. citric acid, four times a day; imperial drink ad lib.; no milk	Evacuated to United Kingdom (sitting case, much oedema) 60 days after onset of thrombosis.
10	25	Paratyphoid B by agglutination	R. femoral	20th day	19 days	20th day: R.13½, L.12½ 31st day: R.13, L.12½	24 days	5 1 citric acid four times daily; imperial drink ad lib.; no milk	Evacuated to United Kingdom (walking case, no oedema) 35 days after onset of thrombosis; little ile.
11	19	Paratyphoid B isolated from stools	L. iliac	16th day	8 days	—	28 days	5 1 citric acid four times daily; imperial drink ad lib.; no milk	Evacuated to United Kingdom (walking case, no oedema) 31 days after onset of thrombosis.
12	19	Paratyphoid B by agglutination	L. femoral	22nd day	18 days	22nd day: R.10½, L.12½ 44th day: R.10½, L.11½	28 days	5 1 citric acid four times daily; imperial drink ad lib.; no milk	Evacuated to United Kingdom (sitting case, no oedema) 40 days after onset of thrombosis.
13	23	Paratyphoid B by agglutination	L. femoral	24th day	7 days	—	13 days	5 1 citric acid four times daily; imperial drink ad lib.; no milk	Evacuated to United Kingdom (walking case, no oedema) 18 days after onset of thrombosis.
14	23	Paratyphoid A isolated from blood	R. femoral	49th day	15 days	49th day: R.12½, L.10 94th day: R.11½, L.10	94 days	10 gr. citric acid four times daily; imperial drink ad lib.; no milk	Evacuated (stretcher case, much oedema) 94 days after onset of thrombosis.
<i>Cases of other Fevers treated by the Oral Method.</i>									
15	21	P. U. O.; clinically suggested an enteric infection	L. femoral	25th day	10 days	—	16 days	5 1 citric acid four times daily; imperial drink ad lib.; no milk	Evacuated to United Kingdom (sitting case, little oedema) 26 days after onset of thrombosis.
16	22	Clinically suggested typhoid	L. femoral	24th day	3 days	27th day: R.13½, L.14 38th day: R.13½, L.13½	14 days	5 1 citric acid four times daily; imperial drink ad lib.; no milk	Evacuated to United Kingdom (sitting case, little oedema) 17 days after onset of thrombosis.
17	23	P. U. O.	Popliteal R. and L.	19th day	15 days	—	23 days	5 1 citric acid four times daily; imperial drink ad lib.; no milk	Evacuated as walking case, no oedema, 47 days after onset of thrombosis.

* That is when patient first left bed after onset of thrombosis. † 0.5 per cent. sodium citrate in normal saline.

Conclusions.

From the above series of cases it would appear justifiable to conclude that the treatment of thrombosis by this method does quickly arrest the process. From the patient's point of view the almost immediate release from pain was most gratifying.

The comparison of a series of cases is always a difficult matter. To obviate this difficulty cases were treated alternately by the two methods, and so may be considered unselected. In reality the cases treated by the intravenous method were, on the whole, the more serious.

Analysis of the two groups shows that in those treated by the intravenous method the subsequent period of pyrexia was shorter by an average of four days and the onset of convalescence by an average of ten days than in those cases treated by the oral method.

Reference to the table also shows that the average number of days from the onset of thrombosis to evacuation in the cases treated by the intravenous method was thirty days, while in those cases treated by the oral method it was thirty-nine. It will, moreover, be noted that, whereas in the series of seven cases treated by the intravenous method five were evacuated as walking and two as sitting cases, and in one only was there oedema present on discharge; in the oral series of ten cases, only five were evacuated as walking and three as sitting cases, while two had to be sent to England as stretcher cases, and in no fewer than five cases there was a considerable amount of oedema present on discharge.

The known facts concerning the action of citrates on the blood as worked out by Sir Almroth Wright would lead one to expect that it would lengthen the coagulation time, and in my own series this is confirmed by the experiments in the coagulation time before and after the administration of sodium citrate in the course of treatment recorded above.

Moreover, not only is the coagulation time increased, but the tendency of the blood to coagulate is diminished. This, as is commonly known, can be demonstrated *in vitro*. With the application of citrate to the blood in circulation, in which as in the case of thrombosis a clot has formed, the formation of further clot is apparently prevented, and such clot as is already formed would then seem to behave in the same way as a clot may be seen to behave outside the body—that is to say, it rapidly shrinks, with the expression of serum, and so opens up the venous channels.

The circulation is then speedily restored, the clot being ultimately absorbed. The better results obtained by the administration of the citrate intravenously than orally would seem to be dependent upon the more immediate and intimate manner in which the drug is brought into relation with the blood by the former than by the latter method.

Lectures

ON

THE ANATOMICAL AND PHYSIOLOGICAL PRINCIPLES UNDERLYING THE TREATMENT OF INJURIES TO MUSCLES, BONES, AND JOINTS.

GIVEN AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND,
NOVEMBER–DECEMBER, 1917.

BY

PROFESSOR ARTHUR KEITH, M.D., F.R.S.,
CONSERVATOR OF THE MUSEUM.

III. THE PRINCIPLES AND PRACTICE OF HUGH OWEN THOMAS.

MEN could not have approached a common objective by more diverse routes than did Hunter and Hilton on the one hand and H. O. Thomas on the other. Hunter and Hilton worked long and hard in the dissecting and *post-mortem* rooms in the search of facts to guide them in formulating rational means of treatment; they observed the efficacy of their methods in regulated hospital wards and on closely tended private patients. The circumstances amidst which Thomas matured his experience were very different: his field of observation was the steady stream of accident cases drawn, from the dockland of Liverpool, which passed through his surgery; his field of experiment lay in his workroom, where, in workman's

attire, and with the hand of an expert, he wrought the exact form of splint or machine which he desired for the treatment of each particular case that came under his care. Here, then, is a surgeon of a new kind, one who could and did use his knife, but it was his final and fixed opinion, founded on thirty-three years crowded with experiments on orthopaedic cases, that the blacksmith's hammer, deftly used, was, in most cases, a more powerful reparative instrument than the surgeon's knife.

Thomas was born and bred an orthopaedic surgeon. His father, Evan Thomas, had his home and surgery, so Professor Rushton Parker has informed me, at 72, Great Crosshall Street, Liverpool, where, although unqualified, he was the referee of certain workmen's clubs—dock gatesmen, ship's carpenters, boilermakers, and several others. He had five sons: Hugh Owen was the eldest; two others besides him—Richard and Evan—studied and qualified in medicine; as the boys grew up they had to help in the surgery and could not fail to gain a first-hand knowledge of injury and disease. Indeed, it was proposed at one time that Hugh should become his father's apprentice, but the ill state of his health—he never at any period of his life was robust—led to a change of plan. In 1851, at the age of 17, he was apprenticed to his maternal uncle, Dr. Owen Roberts of St. Asaph. In 1855, at the age of 21, he went to Edinburgh to study medicine. Syme and Spence and Simpson were in the heyday of their fame; Goodsir was teaching anatomy; there was then a demonstrator of anatomy newly arrived from London—William Turner. Lister was also there commencing the Edinburgh phase of his great career. But in Thomas's writings there is never an allusion to his life in Edinburgh; only one man seems to have impressed him there, Hughes Bennett. He apparently spent little more than a year in Edinburgh, for in 1857 he was studying at University College, London; of his life and experience in London he never gives us the slightest hint. In 1857, in his 23rd year, he became a Member of this College, and in the following year, still in poor health, he returned to Liverpool, where he spent the thirty-three years of his professional life amongst the accident cases of Liverpool dockland. He began in easy circumstances so far as finance was concerned. Professor Rushton Parker informs me that he had at first a very hard struggle, but ultimately acquired the surgeonships of the various clubs which had been held by his father, and that thus an annual income of at least £500 was assured him. His cases supplied him with all his interests—his cases and his workroom where he designed, modified, and perfected the methods he applied for treatment. He knew and sympathized with the working people; there were many poor and ailing men round him who could ill afford to leave their work and seek treatment on week-days; Thomas established a Sunday clinic for them—he eased his poor patients and enriched his own store of knowledge.

Thus he lived from his twenty-fourth to his fortieth years, his fame during that period being still confined to dockland. In 1874 an event occurred which led to his labours becoming better known. Mr. Parker, police surgeon, had reason to visit Mr. Thomas, who then had his surgery and hospital in Greta Street, in connexion with a case—that of an inspector of police—who was then under Mr. Thomas's care on account of a compound fracture of the leg. Mr. Parker had taken with him his son, Rushton, a young surgeon of 28, with an assured future in the Liverpool School of Medicine. We can learn the effect of that visit from the preface which Thomas wrote for his first important publication on *Diseases of the Hip, Knee, and Ankle Joints, with their Deformities: Treated by a New and Efficient Method* (London: H. K. Lewis. First edition 1875; third edition 1878). It was not actually his first publication, for in 1873 he described a method of using silver wire ligatures for the treatment of compound fractures of the mandible. The ligatures were fixed by a terminal spiral which could be conveniently tightened as the mandibular fragments yielded. He also advocated then a practice adopted in the present war, of removing any tooth situated on the line of fracture, as its presence there always retarded union. Once started as a writer he continued to issue *Contributions to Surgery and Medicine* almost annually until death brought an end to a laborious career, handicapped by indifferent health. He died in 1891 at the age of 57. Even in the manner of publication he emphasized his individuality. His writings

were issued in pamphlet form, designed, one would almost think, for only private circulation. It is because of the means he adopted for publication that his numerous writings are so little known; it is very difficult now to obtain a complete set of Hugh Owen Thomas's works.*

He based his methods of treatment on the axiomatic belief which had served to guide Hunter and Hilton—namely, that the power of repair lies in the living tissues of the body. "The crying evil of our art in these times (1883)," he writes, "is the fact that much of our surgery is too mechanical, our medical practice too chemical, and there is a hankering to interfere, which thwarts the inherent tendency to recovery possessed by all persons not actually dying." Further on, in another passage, he adds: "There are actions which Nature cannot do so well as the artist in charge." Spence, whom he must have listened to in Edinburgh, proclaimed that excision of joints opened up a new world in surgery. In Thomas's opinion the world which excision opened up was one of unnecessarily maimed limbs—limbs which could have been saved, or at least cured equally well, had the surgeon been content to play the patient part of Nature's assistant.

It has been said that Thomas's methods of treatment are not founded on a knowledge of anatomy, physiology, and pathology—the only sure basis for a means of cure. That, in one sense, is true. "Surgery is an experimental science," he states. All his life long he kept making experiments in his methods of treatment, closely observing and carefully recording the results night by night. The conclusion he drew from these years of toil was that the more strictly he observed the principle of rest in the methods of treatment he applied to his cases the better were his results. But it would be a complete misrepresentation of the case were it to be said that his methods were not based on a knowledge of the anatomy and physiology of the human body. "Men admired my splints as if I were a blacksmith," he wrote, "but the principles on which they were framed they never could see." We shall examine those principles in connexion with the hip-joint. Thomas never thought in terms of muscles, but of parts. When in ordinary-day life we excite movements, however perfect our knowledge of anatomy may be, we do not think of the muscles which produce them, but only of the segments of the limb we wish to move. That was the nature of his working knowledge of anatomy. He observed that in all movements of the lower part of the body—in walking, turning, or bending—two joints were correlated in their action, the hip and lumbar dorsal joints of the spine. He saw that a limitation in the movement of the hip could be compensated by an increased action in the lower part of the spine, and on that observation he founded his test for demonstrating and estimating the degree of limitation in the movements of the hip-joint. He realized that the hip-joint could not be fixed, could not be given rest, unless the dorso-lumbar region of the spine were also fixed. Movements of the knee also affected the hip; the knee had also to be fixed to give the hip rest. To fix these joints he invented his hip splint—and fashioned it in such a way that it could be fitted and attached to sound parts of the body and could be so placed that it would assist the weaker groups of contracting muscles against their stronger antagonists. He therefore placed the main supporting bar of his hip splint along the back and prolonged it to fit the flexor aspect of the thigh and leg, bent so as to support these parts and relieve the flexor muscles of the hip from those burdens which disease had thrust upon them. He did not know why, but he did know that these muscles would begin to relax so soon as they found they were relieved of their involuntary burden. But he did much more: he saw that the splint must be perfect in its fit and its effectiveness; he saw that that day after day and week after week, moulding the splint as the muscles relaxed, thus leading the parts down the ladder in ease which they had slowly climbed in pain. He carried out, as it never had been carried out before, in cases of diseased hip-joint, a system of "enforced, uninterrupted, and prolonged rest." "A man," he said, "who understood his principles, would do better with a bandage and broomstick than another could do with an instrument maker's arsenal."

When he came to design his knee splint he utilized his

intimate knowledge of the living human body. Nature has two methods of providing limbs with the degree of rigidity necessary for movement: In vertebrate animals she utilizes an internal or central support; in crustacea and insects a peripheral or ensheathing support. We have no reason to suppose that Thomas borrowed any suggestion from the crab or lobster, yet his knee splint is based on the ensheathing principle exemplified by their limbs. He simplified the sheath design by cutting away all unnecessary parts, leaving only a basal ring, with inner and outer bars to represent the complete sheath. He saw that he had to utilize the natural base of the limb—the prominent and fixed parts of the hip bone—as a fixed foundation for the new skeleton with which he was to supply support to the damaged limb. He therefore left intact the basal ring of the sheath, and, by an exact study of the living parts, moulded the basal ring to the supporting points of the pelvis—the ischial tuberosity and projecting iliac parts of the pelvic basin. He gave his sheath rigidity at its distal or pedal end by uniting the lateral supports. He thus furnished the lower limb with a new temporary external skeleton which relieved all its bones of work and stress, and gave the muscular engines complete rest.

We see him again bring his anatomical knowledge to bear on the shoulder-joint. As at the hip, he realized that in all shoulder movements two joints were involved—the scapulo-thoracic and the scapulo-humeral. It was his recognition of this fact which led him to plan a new means for the treatment of dislocations of the scapulo-humeral or shoulder joint. That joint could not be manipulated with precision until the scapula was fixed. He again utilized a basal ring—a fixed basal ring—against which the scapula could be fixed when the arm was drawn through the ring for the purpose of reducing a dislocation of the shoulder-joint.

His knowledge of the physiology of the human body, like his knowledge of its anatomy, was founded on observations made on his patients. Let me cite one of his statements regarding the behaviour of muscles: "The intelligent muscles, finding their labours no longer needed (after application of hip splint), take a rest until invited to enter again on duty." It is a figurative statement, but, as we shall see when we come to deal with recent discoveries of neurologists, it is essentially true. He observed that whenever a joint became diseased, the muscles round that joint became limited in their range of action; the longer the duration of the disease the greater the limitation; if the range began to increase, then that was a sure sign that repair had commenced. He observed these physiological facts; he did not seek to explain them. He also drew an extremely important deduction from these observations: When a patient is able, voluntarily and without pain, to bring a limb or moving part, which has just been released from enforced rest, back to the point or position in which it had been fixed, then that part is cured; the volitional efforts of the patient will, when that stage is reached, effect a full cure. That is surely applied physiology. "If a muscle manifests a flicker of movement under volition, it will recover its full power," is another instance of physiological observation. He treated muscles as he treated his patients. He relieved the weak and oppressed, and restrained the strong. If the flexors of the elbow were paralysed, he saved them from their overstrong antagonists by keeping the elbow partially flexed; he dorsiflexed the wrist-joint by a special splint to nurse the paralysed extensor muscles of the forearm.

We shall have occasion to refer at a later date to other aspects of his methods of treatment—his means of stimulating repair by injury and by "damming"; his opposition to operative measures for securing union of newly-fractured bones, and above all to his condemnation of every form of passive movement as a means of treatment, particularly of the kind applied by bonesetters.

I have touched only a fringe of his career. If I were asked to state briefly the chief lesson we can learn from him, I would not place first his discovery of a fuller meaning to the word "rest," nor his genius in designing new means of giving rest; but rather his realization that repair can be fostered only by the patient personal application of the surgeon's head and hand, day after day, week after week, month after month, if necessary, year after year. He knew that it takes over twenty years to build up any part of the body; how could a destroyed joint be rebuilt in a night?

*Colonel Sir Robert Jones has presented a complete set to the Library of the Royal College of Surgeons of England.

Reports of Societies.

SURGICAL AND DENTAL TREATMENT OF SEVERE FACIAL INJURIES.

At a meeting of the Medical Society of London on December 3rd, the President, Sir ST. CLAIR THOMSON, being in the chair, Major H. D. GILLIES, R.A.M.C., said that the problem of facial restoration resolved itself into three parts: (1) The provision of the skin covering and soft tissues; (2) the general bony and cartilaginous substructure; (3) the lining membrane of the various cavities involved. The greatest difficulty of the plastic surgeon was the question of contour and substructure. To build up the face it was necessary to use normal tissues set in the most normal way. For small depressed scars of the face local flaps of subcutaneous and fatty tissue in the region of the scar might be turned in to fill up the hollow. If local tissue was not available resort might be made to a free fat graft from the abdominal wall or buttock. A piece of cartilage might be inserted, and in the region of the malar bone a flap from the temporal muscle might be swung down to give contour and expression. For substructure of the nose in rhinoplasty cartilage was pre-eminent. In many cases it was possible to line and support a new nose with the remains of the septum or the turbinates. To rebuild the nasal contour the nasal processes of the superior maxilla, the nasal bones, and even the septal cartilage was being imitated by cartilaginous and bony implantations. In the region of the mouth the loss of the muscles was often a serious drawback to an otherwise successful plastic operation. For that reason it was better to cut the flaps in making the upper and lower lips to include muscles of expression, and he preferred a flap which included the musculature to be found in the naso-labial furrows, which had the added advantage of having its base in the line of the facial artery. When the wound involved the oral cavity, the nasal cavity, or the eye socket, the supply of a lining membrane was a problem of equal importance to either the skin covering or the scaffold, both in obtaining a satisfactory appearance and a good functional result. In the majority of cases involving the mouth he used skin flaps turned inwards when they were available and of no use externally, and he supplemented these by carefully designed mucous flaps. When mucous membrane ran short he used a method of epithelial inlay described by Esser. As an instance, to deepen the sulcus of the lower lip so as to free the lip, an incision is made through the chin from the outside, and deepened until the deep surface of the mucous membrane of the mouth is reached; scar tissue is excised, and the cavity widened along the necessary area. The impression of this cavity is then taken in sterilized dental composition, and this model of the cavity is then covered with a freshly-cut Thiersch graft, preferably in one piece, and inserted into the cavity. The skin is sewn up over this epithelial egg, and at the end of ten days an incision is made through the mucous membrane of the mouth, and the model egg removed through this incision. The most perfect epithelialization of the cavity in which the egg has been lying invariably occurred, and by this means the sulcus is established and the lip freed. This method had brought within surgical reach not only the nose which would not contract when it had been made, but also an eye socket that would hold an artificial eye. Major Gillies then showed pictures of various types of cases. In injuries to the cheek with depressed scars flat flaps were turned in from the lateral aspects of the scar and sewn together over the depression with catgut; the skin was cut on the slant, and carefully united with horsehair. Pictures were shown illustrating the results of operations for injuries to the cheek, upper lips, lower lip, reformation of noses, and the deformity caused by the complete detachment of the superior maxilla from the base of the skull.

Captain KELSEY FRY, R.A.M.C.(T.), read a paper on the restoration of the functions of the mandible. He said that the main objective was the restoration of function, and to obtain this it was necessary to achieve (1) bony union, (2) good articulation, (3) mouth in good condition to wear denture, and (4) ability to open and close the mouth. Mastication was lost from 10 per cent. to 90 per cent. unless bony union was obtained. When there was little or

no loss of bone dental splints were made for the mandible and maxilla, and these having been fixed the fragments were firmly held, and this was maintained for two to three months. When there was moderate loss of bone the technique was the same except that the fragments had to be approximated. When there was extensive loss of bone the soft and hard tissues must be held in good position until surgical treatment was possible. When treatment was entirely surgical the means employed depended upon the amount of bone lost. (1) Freshening, plus periosteal graft, was adopted in those cases where the ends of the bone were in good position and the teeth were present on both fragments which would enable them to be firmly held by a dental splint. (2) Wiring, plus periosteal graft, was employed (a) when the ends of the bone were in good apposition but when there were not the necessary teeth to hold the fragments firmly, and (b) when there was only a small interval between the ends of the two bones and when it was thought that by approximating the ends the function of the mandible would not be lost. Bone slides were also used for these two types of case. Bone grafts were performed where there was a large loss of bone and the other methods could not be adopted. The points to bear in mind were (1) never to make a perforation into the mouth, (2) to give absolute fixity to the graft, (3) to maintain strict surgical asepsis, and (4) to lacerate the soft parts as little as possible.

Mr. PERCIVAL P. COLE said that from the point of view of function the bony lesion was of more importance than the injury to the soft tissues, and therefore its efficient treatment should hold first place. Primary suture should not be undertaken when there was an associated fracture unless the fracture could be dealt with at the same time. It was better to wait until all sepsis had disappeared and the wound was soundly healed before undertaking the necessary operative measures. The importance of cicatricial contraction was in direct proportion to its crippling effect on movement. Treatment was directed, first, to the prevention, and, secondly, to the rectification of such limiting effects. In the case of a cicatrizing wound threatening the movements of any particular joint, the surgeon's endeavour was to maintain the joint in that position which would most effectually conserve the threatened freedom of movement. In the case of opening the mouth this could be prevented by maintaining the jaws in a position of open bite. With regard to operative procedures, the introduction of fresh tissue was frequently called for, and for that the use of doubly epithelialized flaps was indicated. Where there was a large demand for mucous membrane skin made an admirable substitute; its texture was suitable and its extent unlimited. The method of "bringing the parts together" was unsatisfactory and should be abandoned. Pictures were then shown demonstrating the various forms of flaps used. In one case the patient was very hairy; in another the flap was taken from the scalp. In such cases depilation by radiations was carried out very successfully, and facilities for treatment by this method might well be provided at any jaw centre or hospital.

VISUAL LOCALIZATION AND ORIENTATION.

A MEETING of the Section of Ophthalmology of the Royal Society of Medicine was held on December 12th, the President, Mr. WILLIAM LANG, being in the chair. A paper on "Visual localization and orientation" was read by Lieut.-Colonel GORDON HOLMES, C.M.G. After referring to an earlier paper by Colonel Lister and himself, he said he purposed collating observations derived from a long series of cases where disturbance of the fields of vision was due to injuries of the visual cortex. There were a large number of cases of comparatively superficial injuries of the occipital region, and commonly associated with these were found central, and particularly paracentral, scotomata. The position of the scotomata above and below the fixation point, and their shape, were found to present a fair correspondence in lesions affecting similar parts of the cortex in the posterior part of the visual area, and indicated a definite arrangement of the centres of that area. Similarly localization could be elicited for the vertical and horizontal meridians of the fields in the walls, floor, and mesial surfaces of the calcarine fissure. More difficulty attended the location of the periphery of the fields. It

was, he thought, to be found in the anterior part of the visual area, but uncertainty arose owing to injuries of this area being so commonly associated with lesions of the optic radiation. From the sharp definition of the half and quarter area losses of fields it was concluded that the fibres of the radiation were ranged in regular lamellae or series; probably the upper and lower quadrants were distinct bundles separated anatomically. A point of interest lay in recoveries of lost fields. These were seen mainly in hemianopia due to slight injuries of the parietal regions. A daily recovery of field from centre to periphery had been noted. He thought such injuries were of the nature of contusions, possibly associated with oedema, capillary haemorrhages, minute lacerations, changes in the myelin sheaths, and even a molecular disturbance of cells, but there was evidently no permanent anatomical loss. Definite lesions of the occipital cortex were, he believed, irrecoverable; the area was so highly specialized that it seemed scarcely likely an adjoining area could vicariously supply the functions of the lost part.

Summing up his observations, Colonel Gordon Holmes said that we were now in a position to draw certain conclusions regarding the localization and organization of the cortical centres of vision, and on the dissociations and disturbances of visual function that might be produced by lesions of different portions of the brain. All the conclusions could not be regarded as final, but they might at least serve as a working hypothesis for further investigations.

1. The upper half of each retina is represented in the dorsal, and the lower half of each retina in the ventral, part of each visual area.
2. The centre for macular or central vision lies in the most posterior part of the visual areas. Probably on the margins and on the lateral surfaces of the occipital lobes. The macula has not a bilateral representation.
3. The centre for vision subserved by the periphery of the retinae is situated in the anterior portions of the visual areas, and the serial concentric zones of the retinae from the macula to the periphery are probably represented in this order from behind forwards in the visual areas.
4. Those portions of the retinae adjoining their vertical axes are probably represented in dorsal and ventral margins of the visual areas, while that in the neighbourhood of the horizontal axes is projected on to the walls and the floors of the calcarine fissures.
5. Severe lesions of the visual cortex produce complete blindness in the corresponding portions of the visual fields; if they cause incomplete amblyopia, colour vision is generally lost and white objects appear indistinct; or a condition may arise in which only more potent stimuli, such as objects moving abruptly, excite sensations.
6. The defects of vision in the fields of the two eyes are always congruous and superimposable, provided that no disease or injury of the peripheral visual apparatus exists.
7. Lesions of the lateral surfaces of the hemispheres, particularly of the posterior parietal regions, may cause certain disturbances of the higher visual perceptual functions with intact visual sensibility, as loss of visual orientation and localization in space, disturbance of the perception of depth and distance, visual attention loss, and visual agnosia.

Dr. JAMES TAYLOR said the paper read by Colonel Gordon Holmes was so full of matter that it was almost impossible to enter into a discussion until there had been time to read it and think it over. But there was no doubt of the value of the work, and, on the suggestion of the PRESIDENT, a vote of thanks was passed to Colonel Gordon Holmes.

Rebulet.

MILITARY MEDICAL MANUALS.¹

WE have received from the University of London Press the first batch of six volumes containing the English translations of the corresponding number of volumes of the Collection Horizon, the publication of which was commenced by the firm of Masson of Paris about a year ago. In our reviews of the French editions we have almost invariably been able to express a favourable opinion, and in what follows we have introduced references to the reviews. The books are short and practical, and are founded upon the most recent clinical and laboratory

¹ *Military Medical Manuals*. Under the general editorship of Director-General Sir Alfred Keogh, G.C.B. London: University of London Press. The price of each volume is 6s. net, with the exception of that by Carrel and Dehelly, which is 5s. net. The price of the volumes of the French edition is uniformly 4 francs.

experience. Sir Alfred Keogh has written a short general introduction to the whole series, in the course of which he observes that if the surgical problems of modern war can be said not to differ sensibly from those raised in the campaigns of the past, the form in which they have been presented is as different as are the methods of solution. The achievements of the chemist, the physicist, and the biologist have given the military surgeon an advantage in diagnosis and treatment denied to his predecessors, and the effects of these advantages are to be measured by the results which have been obtained. In the early stages of the war the conditions at the front were so uncertain that it was impossible to establish the completely equipped scientific institutions for the treatment of the wounded now available, and progress was hampered until definitive treatment could be undertaken at the early stage now possible.

The first volume of the series, that on *Typhoid Fever and Paratyphoid Fevers*, by Vincent and Muratet (BRITISH MEDICAL JOURNAL, 1916, vol. ii, p. 490) is translated from the second (revised) version of the original by Dr. J. D. Rolleston. The first of the surgical volumes of the series is Broca's *After-effects of Wounds of the Bones and Joints* (BRITISH MEDICAL JOURNAL, 1916, vol. ii, p. 804). A translation has been made by Captain J. Renfrew White, and Major R. C. Elmslie has written a short introduction, in which he emphasizes the necessity for an appreciation of the pathology of the lesions of the bones produced by gunshot injuries as a necessary preliminary to their treatment. In England, he says, we have been to a large extent saved from the misuse of the purely mechanical methods by the co-ordination in the orthopaedic centres of mechanical methods with the surgical work, so that every patient who is undergoing mechanical treatment is at the same time under the observation of a surgeon—an ideal method of organization. The volume on *The Treatment of Infected Wounds*, by Carrel and Dehelly (BRITISH MEDICAL JOURNAL, 1917, vol. i, p. 264), has been translated by Captain Herbert Child, and Sir Anthony Bowlby contributes an introduction, in the course of which he says that whenever the Carrel method has been carried out it has accomplished all that has been claimed for it by its author, and that the whole practice of war surgery has been greatly improved by Dr. Carrel's confidence that antiseptic treatment can sterilize a septic wound if sufficient care and skill are bestowed upon it. This lesson, Sir Anthony Bowlby says, was very necessary. The book, as our readers are aware, contains a detailed statement of the method, and Sir Anthony Bowlby says that the only modification that seems justifiable is the use of the syringe when instillation by gravitation cannot be carried out, as in trains, ships, and many units at the front. The utility of the method, he adds, is not confined to recent wounds, so that those surgeons who are treating the wounded in Great Britain will find the book useful. The volume on *Hysteria or Pithiatism and Reflex Nervous Disorders in War*, by Babinski and Froment (BRITISH MEDICAL JOURNAL, 1917, vol. i, p. 843), has been translated by Dr. J. D. Rolleston, and Dr. E. Farquhar Buzzard contributes a short preface. The volume contains a postscript by the authors in which they reply to some criticisms contained in papers published after the French manuscript was complete. The volume on *The Psychoneuroses of War*, by Roussy and Lhermitte (BRITISH MEDICAL JOURNAL, 1917, vol. ii, p. 361), has been edited by Dr. Aldren Turner, C.B. The volume by Thibierge on *Syphilis and the Army*, (BRITISH MEDICAL JOURNAL, 1917, vol. ii, p. 426), has been edited by Mr. C. F. Marshall, who contributes a brief preface, in which he observes that it is too early yet to determine the fate of the syphilitic treated by the new arsenical preparations, and points out that while energetic initial treatment is the best means of rendering men fit for service in the shortest possible time, the proportion of those who will suffer later on from tertiary or quaternary manifestations, such as aortic disease and aneurysm, tabes and general paralysis, remains to be seen.

VENEREAL DISEASES.

SEVERAL additions to the literature of syphilology have appeared recently, among the most noteworthy being treatises by Lloyd Thompson, Leredde, and Thibierge's book on syphilis and the army, a notice of which has

already appeared. LLOYD THOMPSON'S work² is comprehensive and concise. The first part deals with history, etiology, diagnosis, prognosis, prophylaxis, and treatment. As regards the antiquity of syphilis, the author preserves an open mind. In discussing the various details of laboratory diagnosis, both microbiological and serological, which are well described, the author attaches great importance to the Wassermann reaction, a modification of which he describes. In the chapter on treatment the different methods of administration of mercurial and arsenical preparations receive full attention, including several methods for intravenous injection of salvarsan and neo-salvarsan in dilute and concentrated solutions. The account given of the introduction of salvarsan shows that the author has an insufficient acquaintance with the historical facts, and he may be glad to have his attention drawn to a paper published in this JOURNAL on April 29th, 1916, in which Dr. Benjamin Moore relates the true history. He pointed out that salvarsan and neo-salvarsan are simply derivatives of atoxyl, which was discovered by the French chemist Béchamp in 1863; that the first use of the new arsenical preparations in the treatment of protozoal diseases was made by a Canadian working in a British laboratory; that the chemical nature of atoxyl was shown simultaneously in England and Germany; that Ehrlich and others in Germany "finessed amongst the derivatives to find the compounds best adapted for therapeutic use" and selected salvarsan; and finally that they kept the details of its production secret. All this was done in the characteristic German way without any acknowledgement of the previous discoveries which had led up to the production of salvarsan, which was patented for the commercial benefit of the Fatherland. Fortunately, owing to the war, this drug is now manufactured outside Germany. The remainder of the volume deals with the systematic description of syphilis of the various systems and organs of the body. The book is well illustrated and well written, and we can recommend it as a valuable handbook on the subject.

Dr. LEREDDE,³ a former advocate of intensive mercurial treatment, has produced a treatise which might be entitled the apotheosis of salvarsan. Always an extremist, he has now renounced mercury in favour of exclusive treatment by arseno-benzol. He does not even advise combined treatment; the reasons he gives are that such treatment is based on the assumption that certain spirochaetes may be resistant to arsenic; that this has not been proved in the case of spirochaetes as it has been in the case of certain trypanosomes; and finally, that combined arsenical and mercurial treatment depends on inductions and hypotheses, not on facts, and has no precise experimental or clinical basis, especially in recent syphilis. We were under the impression that mercury was associated with arsenic because it had long been found to have a curative effect on syphilis, while the action of arsenic was still in the experimental stage. Dr. Leredde's method of treatment consists in intravenous injections of neo-arseno-benzol in progressive doses, administered on the average once a week. In a man of 60 kilos weight the first three doses are 0.15, 0.20, and 0.30 gram, subsequent doses being increased by 0.15 to 0.30 gram, according to the indications furnished by the reaction. This treatment is carried out continuously, in primary and secondary syphilis, till the serum reaction is negative and the cerebro-spinal fluid normal. After an interval of three weeks "an injection of reactivation" of 0.45 gram is given, and the cerebro spinal fluid examined in five days. If this is negative, the patient is considered cured; if positive, the course is repeated. In many cases of primary or secondary syphilis ten to fifteen injections are required to produce this result; in one case of primary syphilis mentioned twenty injections were necessary, in doses varying from 0.30 to 1.35 grams. In old cases of syphilis the same treatment is adopted, but intermittently with intervals of not longer than three weeks. The treatment is controlled by examination for arsenic in the urine by Abelin's method. Leredde does not countenance the marriage of syphilitics unless they are "in a state of absolute or

relative sterilization," which he claims can be produced by the above treatment. We venture to regard this as a counsel of perfection and a condition impossible of proof, except by experimental inoculation. He attributes the failures and many of the accidents after treatment by salvarsan to the doses being too small, too infrequent, too irregular, or given at too long intervals. Leredde states that arseno-benzol is less toxic than mercury, and that when administered for a long time it produces fewer accidents than those caused by the prolonged administration of mercury. This statement is open to question, although the accidents due to arseno-benzol are certainly less frequent now than was formerly the case. The chapters on the pathology, microbiology, symptomatology, and sociology of syphilis are adequate, but no reference is made to any of the observers who claim to have described life cycles or spore formation in spirochaetes. Leredde's work will be read with interest by syphilologists, but it can hardly be recommended as a guide for treatment in the present state of our knowledge.

Mr. REGINALD HAYES⁴ has brought out a second edition of his little book on the Aachen treatment of syphilis, the first edition of which was reviewed in this JOURNAL on May 15th, 1915. The Aachen method consists in the inunction of a 33 per cent. mercurial ointment by a skilled rubber under medical supervision, combined with the internal and external use of sulphur waters. This method can be, and is, carried out in this country perfectly well. Mercurial inunction is one of the oldest, and is still probably the most effective, method of mercurial treatment. The reason why it is not more generally used is that it is difficult to carry out without compromising the patient. However, now that there is less secrecy concerning venereal disease, this objection may not carry so much weight. Mr. Hayes does not claim that this treatment does away with any indication for salvarsan, but he gives it the place of honour, and regards salvarsan only as a valuable auxiliary. In fact, the method he adopts consists in a ten weeks' course of inunction, associated with three intravenous injections of full doses of salvarsan. In a fair proportion of cases, he says, the blood test has become negative after this course, and remained so for several years, even after a provocative injection* of salvarsan. We can recommend Mr. Hayes's book as a sound guide to those who wish to carry out this too much neglected form of treatment.

In reading recent books on syphilis it is astonishing to note the divergence of the views expressed. We hear a good deal nowadays of the "modern treatment of syphilis," but while all agree that energetic treatment in the early stages offers the best hope of cure opinions differ widely as to the best method of treatment to adopt. At one extreme is Leredde, who argues that salvarsan is all-important and that mercury should be discarded; at the other extreme is Hayes, who gives mercury the first place, with salvarsan as an auxiliary only; between these two extremes are Thompson and Thibierge, who regard both mercury and salvarsan as essential. In the present state of knowledge, as the ultimate results of salvarsan as regards its power in preventing the later quaternary manifestations of syphilis, such as aortic disease and aneurysm, tabes and general paralysis, have not been ascertained, it would seem that Hayes's view is the soundest. The true efficacy of a drug in the treatment of syphilis lies in this power, not in the rapid healing of chancres, which heal quickly enough under any effective treatment, nor in the rapidity of the supposed disappearance of spirochaetes from the lesions. The latter argument is fallacious, as spirochaetes are not always easy to find, and a negative finding does not prove their absence, and moreover, the possibility of spore formation is ignored. Again, as to the Wassermann reaction, while all agree as to its value in diagnosis when taken in conjunction with clinical evidence, Lloyd Thompson and Leredde regard it as of prime importance as a test of cure and a guide for treatment, but Thibierge considers it of absolutely no value in this connexion. One fact not sufficiently recognized is that the presence of mercury or arsenic in the blood interferes with

² *Syphilis*. By Lloyd Thompson, Ph.B., M.D., Physician to the Syphilis Clinic, Government Free Bath House, etc. Philadelphia and New York: Lea and Febiger. 1916. (Roy. 8vo, pp. 433; 7 plates, 77 figures, 425 dollars.)

³ *Domäne, traitement et prophylaxie de la syphilis*. By E. Leredde. Paris: A. Maloine. 1917. (Roy. 8vo, pp. 481; illustrated. Fr. 14.)

⁴ *The Intensive Treatment of Syphilis and Locomotor Ataxia by Aachen Methods*. By Reginald Hayes, M.R.C.S., etc. Second edition, revised. London: Baillière, Tindall, and Cox. 1917. (Cr. 8vo, pp. viii + 147; 22 figures. 4s. net.)

the reaction. An interval of four weeks should elapse between the cessation of treatment and the test. Hence repeated tests made during the course of treatment are of little or no value.

Mr. FRANK KIDD⁶ has published his lectures on common diseases of the male urethra, with the addition of several appendices. These lectures have already been printed in this JOURNAL. Although somewhat dogmatic the advice given in this book is sound and practical. Some, however, will think that the author is unduly enthusiastic as to the results obtained by urethroscopic treatment. The appendices form an interesting addition to the lectures, and contain notes on illustrative cases, and details for fitting up a room for urethral examination and treatment. The author's evidence before the Royal Commission is added. The book is well illustrated, and can be recommended as a useful guide in the treatment of gonorrhoea and its complications.

NOTES ON BOOKS.

THE small *Handbook of Surgical Operations*, by Mr. CHATTERJI, is, according to the author's foreword, designed to give aid and guidance to students and teachers of surgery. The work deals solely with the actual conduct of operations, and makes no attempt to discuss such questions as preliminary or after treatment. The author does not claim to describe all the methods of performing the various operations, but only those which he himself has found to give the best results—for example, Bassini's is the only operation described for the radical cure of inguinal hernia, and the large anterior flap is the sole method described for amputation through the thigh. Space is wasted in describing such obsolete procedures as Lisfranc's and Chopart's amputation of the foot, and Mr. Chatterji acknowledges that they have nowadays little claim for mention. Many minor but exceedingly useful points are referred to, such as the methods of holding a scalpel, the proper way of making an incision, and the manners of employing sutures and tying knots. The ligature of arteries is dealt with fully, as are also amputations and disarticulations. Excision of bones and joints, tenotomy, operations on nerves, tracheotomy, abdominal operations, and operations on the urethra, penis, and testis are the other procedures described. But, strangely, no mention is made of many common operations, such as osteotomy, operations for varicose veins, varicocele, haemorrhoids, femoral hernia, suppurative and other varieties of peritonitis, osteomyelitis, etc. The important subject of intestinal obstruction is very briefly referred to. The work is well illustrated by a number of black-and-white and coloured plates.

⁶ *Common Diseases of the Male Urethra*. By Frank Kidd, M.B., B.C. Cantab., F.R.C.S. Eng. Being a course of lecture delivered at the London Hospital, with an additional lecture on the Clinical Pathology of Urethritis, by Dr. Philip Panton, Clinical Pathologist, London Hospital. London: Longmans, Green and Co. 1917. (Demy 8vo, pp. vii + 132; illustrated. 5s. net.)

⁷ *A Handbook of Surgical Operations*, designed for the use of students of surgery. By K. K. Chatterji, F.R.C.S.I., Teacher of Descriptive and Operative Surgery, Campbell Medical School, Calcutta: Butterworth and Co. 1916. (Demy 8vo, pp. 238; illustrated. 7s. 6d. net.)

THE HEALTH OF THE SCHOOL CHILD.

IN the JOURNAL of October 6th we noted the publication of the annual report for 1916 of the chief medical officer of the Board of Education,⁸ and discussed the leading points in Sir George Newman's introductory paragraphs on the aims and functions of school hygiene. In the brief space now at our disposal we propose to indicate some of the principal matters dealt with in the body of the report.

The School Medical Service.

War conditions and the demand for medical men for the military service of the country have made a heavy call on the staff of the educational medical services. In the view of the Board, in the event of a temporary curtailment of the school medical service becoming necessary, provision should at any rate be made (a) for the medical inspection of children of all ages who appear to be ailing; and (b) for the maintenance of any treatment at that time being undertaken by the authority.

Inspection on this limited scale is now in vogue in an

⁸ Annual Report of the Chief Medical Officer of the Board of Education, 1916. (Cd. 8746.) H.M. Stationery Office. 1917. To be purchased of all booksellers. Price 1s. net.

increasing number of areas, 92 as against 48 in the last year under review. The total roll of the elementary schools is now 5,306,411. The number medically inspected to December during 1916 was 1,446,448, as against a normal average of 2,000,000. The decline in inspection is about 28 per cent. The work is done by some 1,257 medical officers, not including the 215 medical practitioners who take part in the London school clinics; besides, there are 1,527 school nurses. The limitation of the school medical inspection has drawn teachers into the work of personal observation of the health of their pupils, with beneficial results. Dr. Nash of Norfolk, with this end in view, has published an excellent series of hints to teachers which is reprinted in the report. It might well be circulated to all teachers.

Attention is drawn to the altered character of the work of the school attendance officer. Formerly he was a true pedagogue, and as such a source of fear to the truant. Now he is a veritable scout of the medical service, and is able to furnish valuable information of illness and defect which is greatly to the advantage of parents, children, and the medical service. In this connexion there is necessarily overlapping in the work of the attendance officer and of the school nurse. In some areas there is a tendency to replace the attendance officer by the nurse.

Emphasis is laid on the necessity for co-operation and continuity of agencies, both municipal and voluntary, which busy themselves with infant and child life. Children's care committees should recognize that they are properly a link between agencies having at heart the care of mothers to be and in being, through the midwives, the schools for mothers, and later the infant welfare centres, day nurseries, and classes for mothercraft amongst the elder girls.

Medical inspection is being extended to secondary schools, although, on account of a lessened staff, at a slower rate than in recent years. The need for this is shown in the observations made through the personal hygiene scheme working in the girls' secondary schools in London. In the works of the report—

The desirability of the extension of the school medical service (including medical and dental inspection, medical treatment, and the various branches of school hygiene) to all secondary schools, continuation schools, and schools other than elementary, would seem now to be abundantly established, and it is hoped that in the near future these advantages may be available for children of all classes.

Care and Training of Young Children.

Schools for mothers and day nurseries are increasing in number: there are now 360 for the year 1917, as against 281 in 1916 and 236 in 1915. The day nursery provides primarily for the children of mothers who are obliged to go to work away from home and who wish to ensure the proper care of their children for the whole day. Children from one month to five years are admitted, but most of the children are under three years of age. The attendance is often fairly regular, as mothers have definite days on which they work. A daily charge, usually 4d. to 6d., is made towards the cost of maintenance of the nursery. It is open, as a rule, from 6.30 or 7 a.m. to 6 or 7 p.m., and is closed on Saturday afternoon. It is in charge of a matron assisted by nurses and probationers. The staff are nearly always resident and are responsible for the management of the children and the nurseries, though additional help in the kitchen or laundry may be provided. The more modern nurseries provide some open-air life, in garden, yard, or roof playground. The infants are weighed once a week, and simple records are kept of physical condition. The nurseries are voluntary institutions, but since 1914 the Board has made a maintenance grant of 4d. per child per attendance of not less than nine hours.

Nursery schools have been established in many places by voluntary agencies, taking children from 2 or 3 years of age to 5 or 6. The Board has no control over these, and makes no grants in aid; but it is evidently very sympathetically inclined to them, and a detailed account is given of their working. In these nursery schools is to be found the possible line of reform of the existing infant school, which is too formally planned on the lines of the departments for boys and girls with which they are linked.

Medical Inspection.

The medical inspection of school children has been much restricted by war conditions. Fortunately there was in

1916 a continuance of relatively good health among the children.

Malnutrition and insufficiency of clothing among school children were, in 1916, less than in former years in some areas. It is significant that whilst the health and personal condition of entrants shows little or no betterment, that of the eight years old and leaving children shows a steady improvement. Those school doctors who have been at work on this subject for ten or fifteen years are able to report a substantial improvement in the physical condition of the older children. This is a very important fact.

Uncleanliness is apparently declining in certain areas, both in extent and degree, which is due to the vigorous action taken by the local education authorities and to the response of the parents. The return for London for 1916, where the 'cleanliness survey' is most thoroughly carried out, and where a high standard of cleanliness is required, shows that 25 per cent. of the children are unclean. There has been a serious increase in the number of cases of scabies amongst the children in some parts of the country. Most of the cases could be traced to contact with soldiers home on leave, not only from France, but also from military camps in this country.

Defects of vision still attain high percentages, and attention is again drawn to the constant excess of visual defects amongst girls which never fails to be brought out in the results of medical inspection, and "appears to be a conclusive demonstration that close application to fine work is a potent means of producing defect in childhood." Reports on the effect of cinematograph displays are cited, and in connexion therewith are given lengthy abstracts from a paper by Mr. Bishop Harman published in the *JOURNAL*, February 17th, 1917. The fact that the returns of defect of vision are higher for the year under review than previously "lays upon the local education authorities a large burden of responsibility."

The provision of sanatorium schools for children suffering from tuberculosis is slowly increasing; there are now twenty-four such institutions, as against eighteen in the previous year. The Finance Act of 1911 made available a sum of £1,500,000 for the provision of sanatoriums and other institutions for the treatment of tuberculosis in the United Kingdom. Of this amount £100,000 was earmarked as capital grants for providing sanatorium schools for children. The distribution of these grants rests with the Local Government Board. By agreement with them the Board of Education approve the plans, and carefully consider the arrangements for the education of the children.

Medical Treatment.

From the reports and tables given it appears that about 58 per cent. of the children found defective received treatment. There are 319 local education authorities.

Less than half of the authorities have made any attempt whatever to provide dental treatment, and with one or two exceptions the provision made by 146 authorities is at present wholly inadequate. There are still approximately 190 authorities which have done nothing for minor ailments or defective vision, and 200 have done nothing for diseases of the ears and the throat. Yet for nine years there has been a steady flow of incontrovertible evidence of the prevalence of these maladies, and during the last three years tens of thousands of young working people and of recruits have found themselves unable to render full service to the country owing to dental decay and defective vision, the treatment of which was neglected in childhood.

A hint is given that for the future, in assessing grants by the Board, there will be a stricter scrutiny of the adequacy of medical treatment provided.

Reference is made to the work of the blind schools, and in particular to the report of the Departmental Committee on the Welfare of the Blind, which has recently been reviewed in these columns. The work of the special classes for myopic children is commented on. London has now seven of these classes. Bradford has made an experiment in combining these classes with open-air work.

Open-air Schools.

It is estimated that 10 per cent., or 600,000, of the school children suffer from debility, anaemia, and malnutrition, so that they are stunted and weakly, and unable to derive reasonable benefit from their schooling. For them the best possible treatment is an open-air school.

An article by Professor Leonard Hill on the physiological advantages to be derived by children from an appropriate application of the open-air method of education

is printed on pages 104-106. It will repay study. Many authorities have started classes in the playground of schools and in public parks; the teachers state that "the scholars taking part become brighter, more vigorous, and much more alert, resourceful, and mentally receptive." Associated with this effort are the school journeys to country places, holiday camps, and schools. Between the open-air schools and the sanatorium come the residential open-air schools of recovery, intended mainly for non-tuberculous children. There are now a dozen of these throughout the country.

Physical Education.

One of the lessons which the war has emphasized is the necessity to secure the full personal physical development of the child, not only for his own benefit and happiness, but also from the point of view of his value to the State. One way in which this can be done is by making suitable physical training an effective part of the education of every boy and girl, by getting rid of the old and narrow conception of "drill" in the schools, and by giving the subject and its exponents appropriate recognition and status.

The share of play in education is noted:

It has not been sufficiently realized that play is, after all, a serious business, that beyond a certain point children cannot invent and teach themselves games, and that to secure the utmost usefulness from the time allotted to play children must be actually taught games, though they should subsequently be encouraged to play them in a spirit of freedom, with the minimum of direction from adults.

The grand adventure of make-believe has an educational and physical value of its own. Play centres should be facilitated. The school playgrounds and buildings should be available for these in the winter months, but in the summer activities should be transferred to playing fields. Special appeal is made to local authorities to allocate to children playing fields in parks and other open spaces far more generously than has been done in the past, and not only to provide ground, but also to equip it for the games. Dancing, one of the oldest means of self-expression, is needed to complete the physical education. The whole question of dancing in association with physical training requires fuller investigation and experiment.

Provision of Meals.

The decline in school feeding in 1915 and 1916 is remarkable. Fewer children are being fed to-day at the cost of the State than when the Acts were first put in operation. Before the war the average number of children fed per annum was approximately 150,000. In 1915 it was 422,000; in 1916, 117,000. Immediately on the outbreak of the war the figures rose rapidly, but after October, 1914, they as rapidly declined. The causes of this decline are obvious—there was a great increase in wages associated with a rapid increase in employment.

Control of Juvenile Employment.

The increase in the employment of children and young persons in 1915-17 in munition work and otherwise has demonstrated that many boys and girls are being spoiled physically, mentally, and morally.

It must not be assumed that all employment of such children is physically a disadvantage and to be deprecated. Much depends upon sex and age of the child, its health and strength, its previous training or experience, and its home life; much depends on the condition of employment, the character of the work, its educational or training value, whether indoor or outdoor, the period and length of hours to be worked, the strain and stress involved. . . . It is a question of proper control rather than absolute suppression; of wise selection rather than prohibition.

A mass of evidence from school medical officers is given of the effect of juvenile work, and from this the conclusion is drawn that while gross and immediate physical injury is not occurring as a result of excessive or premature employment, the strain of such employment, combined with schooling, cannot be supported by the child's body without undermining its physique.

The remedy is threefold: (a) No child under 14 should be exempted from education, half-time or whole-time, for purposes of employment for profit; (b) no child attending school should be employed out of school hours except at prescribed times and for prescribed periods; (c) the employment of all young persons from 14 to 18 should come under medical supervision and control.

British Medical Journal.

SATURDAY, DECEMBER 22ND, 1917.

EPIDEMIC CEREBRO-SPINAL MENINGITIS.

SINCE early in the year 1915 we have been living through a scattered epidemic of cerebro-spinal meningitis, and a great deal of bacteriological and epidemiological work on the organism causing the disease and its modes of transmission has been published since that date. Among the most recent of these publications is a collection¹ of *Further Reports on Cerebro-spinal Fever*, issued by the Local Government Board in continuation of its report of 1916. In a preliminary memorandum by the Board's medical officer, Sir Arthur Newsholme, it is pointed out that the meningococcus is a delicate organism incapable of growth or survival at a temperature much below that of the human body. Its habitat is the human nasopharynx, where it may grow readily. It is transmitted from person to person in droplets expelled by forcible expiration from the carrier and inhaled by those in his proximity. It may also be conveyed from mouth to mouth either by direct contact, or, possibly, by some article infected by the mouth of the carrier. There is no evidence of more indirect or more distant modes of transmission.

It must be fully recognized that the meningococcus is a common inhabitant of the nasopharynx, and that its presence there rarely leads to the development of meningitis. Generally it behaves as a harmless saprophyte in non-epidemic periods. Thus Mayer and his colleagues found 158 meningococcus carriers among 9,111 soldiers at Munich in 1910, an epidemic-free period; none of these carriers developed meningitis. The significance of these figures will be appreciated better when it is realized that the meningococcus does not usually persist in the nasopharynx of a carrier for more than two or three weeks; so that a large proportion of the population must harbour the organism at one time or another, even during a non-epidemic season. At the present time the proportion of carriers in England is probably much higher than it was in Munich in 1910. Between March, 1915, and February, 1917, 1,881 persons believed not to have been in contact with cases of cerebro-spinal fever were examined by bacteriologists working for the Board, and 253 of them (13.5 per cent.) were found to be meningococcus carriers. In the three years 1912-14 there were about 300 cases of the disease in England and Wales per annum; the figure rose to 3,702 in 1915; it was 2,199 in 1916, and there were over 1,000 cases among civilians alone during the first six months of 1917. Nearly four-fifths of the cases among civilians occurred at ages under 15, and about 60 per cent. of all the cases arise in the months of March, April, and May.

Not much has been ascertained as to the conditions under which epidemics of the disease arise; there is some resemblance here between influenza, cerebro-spinal fever, and other catarrhal respiratory affections. In fact, it may be generally stated, from the point of view of the epidemiologist, that cerebro-

spinal fever is one of a group of catarrhal diseases, and that it commonly becomes prevalent at or a little after the season of the year and under climatic or other conditions which favour excessive prevalence of influenza, bronchitis, and pneumonia. Its response to these influences, however, is erratic; it is not associated with dry years, or a series of dry years.

When considering the infectivity of the disease we are on surer ground. The risk of infection from a case of cerebro-spinal fever is small, even very small; in the vast majority of instances only one case occurs in an invaded household or military hutment, and sometimes only one case in an invaded locality. Thus among 2,343 cases among civilians in 1915, multiple cases occurred in 150 only of the invaded households. It is exceptional for the infection of a patient to be ascribable to any known case of cerebro-spinal fever; clearly he must have picked up the meningococcus from some carrier, but as the percentage of healthy carriers is as high as 13.5 among members of the general population in populous areas who have apparently had no opportunity of contact with a case of the disease, it seems highly probable that the carriers are more important than the cases in the causation of epidemic cerebro-spinal meningitis. Further, it is pointed out that the sporadic habit of the disease, in point of both time and place, persists in epidemic times. The case rate is not deducible from the carrier rate, and the occurrence of an epidemic cannot be satisfactorily explained as due to an increase in the latter. Evidence is brought forward by five of the contributors to this volume of Reports to show that any microbe possessing the admitted morphological and cultural characters of the meningococcus should be regarded as potentially pathogenic; appeal to agglutination reactions here is held to be superfluous, though differences in these serological reactions may be regarded as having importance in directing the treatment of cerebro-spinal fever by serum-therapy. Major Gordon, as is well known, does not accept this view as to the value of agglutination reactions, and much weight must be given to his opinion.

The further consideration of the healthy meningococcus carriers who are mainly responsible for the occurrence of cases of the disease suggests certain possibilities with regard to its spread. Clearly the carriers are too many to be controlled or quarantined in the ordinary conditions of life. The carrier condition may be of benefit to the individual as a means of acquiring partial immunity to the disease, but it is clearly harmful to the public as increasing the circulation of the meningococcus and facilitating the infection of susceptible persons. Again, some such susceptible persons may be a danger to others by raising the virulence of the nasopharyngeal meningococci to epidemic pitch, and before themselves falling victims to the disease may transmit these more dangerous organisms to other persons. Alternatively, epidemics of the disease may be due to the temporary enhancement of the virulence of endemic strains of meningococci by some conditions still unknown to us. The view that a more virulent strain may have been introduced into this country from Canada early in 1915 is said to be possibly correct but unproven; some military cases of cerebro-spinal fever had occurred in this country before this importation could have taken effect. Can anything be done to lessen the prevalence of cerebro-spinal fever in the future? The infecting agent, as has been stated above, has its habitat in the nasopharynx. It is transmitted from one person to another by such actions as coughing or sneezing without the careful use of the handkerchief;

¹ Reports to the Local Government Board on Public Health and Medical Subjects. New series, No. 114. Pp. vi + 214. H.M. Stationery Office, London. 1917. Price 4s. net.

or, more directly, from mouth to mouth, as in kissing. Sir Arthur Newsholme looks forward to the time when a higher standard of conduct in regard to the spread of all such catarrhal infections will become the rule in social intercourse. Everyone will agree with him that the practice of coughing and sneezing broadcast, now unhappily so common, should be put a stop to in the interest of the public health. As for the prohibition of the more direct method of infection, even the least susceptible of bachelors would think twice before making so unreasonable a suggestion between Christmastide and the New Year.

THE FOOD REQUIREMENTS OF THE SEDENTARY WORKER.

LAST week we gave reasons for thinking that a drastic reduction of the standard of meals in restaurants and also in clubs was psychologically desirable and physiologically correct. We will endeavour to define the scale of living which might be adopted by well-to-do sedentary workers.

Since exact measurements of the amount of muscular work performed by sedentary persons are unobtainable, we can, on experimental grounds alone, proceed no further than to assign as a minimum a daily intake of 1 calorie per kilo and hour—that is, 1,680 calories a day for a man of 70 kilograms (15 stone). The amount required in excess of this must be judged from statistics and controlled by individual experience. Unfortunately, statistical data are especially difficult to interpret when they relate to persons whose incomes enable them, in comparison at least with the hand-working classes, to satisfy their inclinations in the matter of food consumption; custom and the artificial standards of society have to be allowed for. Atwater and his associates concluded that 2,500 calories should suffice for men with very little exercise, and 3,000 for those at light physical work, values which are exceeded by the means found for American professional families in many inquiries.

Most of the European diet studies which had been published before 1902 are collected in R. O. Neumann's paper.¹ His table includes thirty-three observations upon professional men whose diets were found to be sufficient for equilibrium. The mean number of calories a day (reduced to terms of a standard body weight of 70 kilos) was 2,938. Neumann, who was at the time a privatdozent and assistant in the Kiel Institute of Hygiene, provides a valuable series of observations upon himself. The particular importance of these lies in the fact that they represent a continuous study extending over 746 days. In different periods Neumann's calorie intake varied from 1,999 to 2,427 (reduced to terms of 70 kilos body mass; the author's weight was actually between 66 and 67 kilos in the earlier and 71 to 73 in the later experiments). The concluding series, covering eight months' observations, gave a mean of protein 74 grams, fat 106 grams, carbohydrate 164.2 grams, and alcohol (in beer) 5 grams. The total energy value was 1,999 calories. Neumann inferred that sedentary workers like himself might well conform to a standard of about 74 grams of protein, 56 grams of fat, and 360 of carbohydrate, yielding an energy value of 2,300 calories. It would, no doubt, be rash to draw general conclusions from the experience of an individual, even though it covered a considerable period of time, and the proposed value is less than the Atwater standard and *a fortiori* less than the statistical mean, but there are various records, especially the well-known observations of Ranke, which agree substantially with Neumann's

experience. We think that for the sedentary male worker who is able to secure adequate protection from cold and who takes little outdoor exercise a daily ration of 2,500 calories ought to suffice. We are here allowing for the average body weight being rather below 70 kilos and for waste in preparation of food, the former factor reducing and the latter increasing the requirements, as expressed in food purchased.

As we have seen, the voluntary ration allots the sedentary male worker about 1,680 calories, leaving on the proposed basis a deficit of 820 calories to be provided from unrationed articles.

So far as London is concerned, three foods of high energy value must be considered—milk, dried fish, and potatoes. The supply of milk is already below the requirements of the population, and will no doubt be distributed preferentially in the near future. A quarter of a pint daily, providing 102 calories, seems to be a maximum figure for the sedentary male. Dried fish is, on account of transport conditions, more likely to be available in London and in the great northern cities than elsewhere, and a daily provision of 2 to 3 ounces (74 to 111 calories) might be feasible. This leaves some 610 calories to be furnished by potatoes; this represents from 1½ to 2 lb. of potatoes, according to quality, making allowance for waste. It appears to us that all articles of food, other than potatoes, supplied to restaurants and clubs should be rationed on the above scale. The practical difficulty which suggests itself depends on the fact that only a small minority of the customers obtain all their meals in a club or restaurant. A way to surmount this is indicated in Dr. Leonard Hill's memorandum²; it is to ration on meal values. The three principal meals are each allotted the values 0.2778, and tea is reckoned at 0.1666, this being the distribution of daily intake observed in Dr. Hill's inquiry. The method would apply as follows: Suppose in a given restaurant 1,000 lunches, 500 teas, and 1,000 dinners were served in a week. The meal value would be $2000 \times 0.2778 + 500 \times 0.1666 = 639$; that is, the consumption corresponds to the complete rationing of 639 men for one day. On the voluntary ration for sedentary workers this gives 411 lb. of bread, 68½ lb. other cereals, 182½ lb. of meat, 45½ lb. of sugar, and 57 lb. of fats. Managers would, of course, have to arrange their menus to conform to these regulations. Provided potatoes are unrestricted,³ there is not the slightest risk of any persons in the category of sedentary workers who frequent restaurants and clubs going short of food, and the curtailment of the use both of fat and milk which is implied (the allowance of milk by the proposed method of calculation would in the example given be 20 gallons) seems both just and necessary.

A further criticism to which the proposal is subject is that casual light refreshments need special treatment. If no margin is granted for these, the regular clients will not be able to get their proper ration; conversely, if any order for a glass of sherry and biscuits is reckoned as a "lunch," those who take the stated meals will be over-rationed. It ought not to be very difficult to frame a rule to cover these cases, but, so far as our observation goes, they are not really important in the expensive restaurants. Of course, persons who lunch *à la carte* can properly be treated on the meal basis applicable to *table d'hôte* customers.

² No. 19 Health of Munition Workers Committee, revised edition.

³ Attention may be again directed to the excellent utilization of the nitrogen of potato. Thomas (*Arch. f. Phys.*, 1909, pp. 219-302) found 5½ grams of potato nitrogen biologically equivalent to 13 grams of nitrogen from wheaten bread.

¹ *Arch. f. Hygiene*, xl, 1902, p. 1, etc.

The principles developed in the preceding paragraphs have equal applicability to the consumption of tea, coffee, and cocoa, but these articles having little or no energy value, at least in the form ordinarily used, do not require consideration here.

THE WAR FUND OF THE ROYAL MEDICAL BENEVOLENT FUND.

A LETTER commending the claims of the War Fund of the Royal Medical Benevolent Fund will be found at p. 842. A general appeal was issued some time ago, but that published to-day is a direct appeal to the members of the British Medical Association in the Divisions, and is made by the principal officers of the Association—the President, the Chairman of Representative Meetings, the Chairman of Council, and the Treasurer. The Fund has been established to help the many medical men who, when called upon to enter the military service of the army or navy, had to leave, often at very short notice, without time to make adequate provision for the continuance and maintenance of their practices during their absence. They have had to face a severe fall in income, even when supplemented by army pay; and standing expenses, such as rent, insurance, the maintenance of a family, and the education of children, have continued. While it is hoped that in a year or two after their return those affected will recover their position, in the interval help is and will be necessary. The appeal is for at least £30,000, for to be effective the grants must be on a liberal scale. Towards this sum about £4,000 was contributed last year. In the subscription lists published during the last five months some large contributions from members of the profession have been announced; there have been several of £500, some of one hundred or fifty guineas, many of twenty, ten, and five guineas, and a large number of smaller sums, but it is a case in which every member of the profession should endeavour to do as much as he can. It is hoped that the appeal through the Divisions of the Association will facilitate the collection, especially of smaller amounts, which, in the grand total, will help to attain the sum it is considered the lowest the profession should provide.

MEDICAL INSURANCE AGENCY AND MEDICAL BENEFIT.

At the meeting of the Committee of the Medical Insurance Agency on November 22nd the chairman, Dr. G. E. Haslip, was able to report that the amount of business transacted had been satisfactory, in spite of the unsettled conditions due to the war. Notwithstanding the restrictions on the use of petrol, and the fact that so many medical men are absent from their practices on military service, the business in insurance of motor cars had continued to grow, members insured through the Agency having found that claims were promptly settled and that the arrangements for repairs in the event of an accident proved highly efficient. This being so, those medical men who have not yet insured through the Agency would be well advised to give it an opportunity of explaining its arrangements and giving quotations. During the absence of the owner cars are insured against fire risk only, and the premium paid is therefore smaller, but it was considered reasonable to expect that when owners returned full policies would be resumed. The amount of life business done at the office was, Dr. Haslip said, a very satisfactory feature, as it showed that the confidence in the advice given by the agency was steadily growing. It was not restricted to any particular office, and before advising on the best form of contract the special circumstances of each case were carefully weighed and considered. The agency affords an example of what can be accomplished by co-operation within the

profession. That policy holders enjoy the advantage of a substantial discount is shown by the fact that since the agency started £6,500 has been allowed to the insured by way of direct benefit, while at the same time they have the satisfaction of knowing that by insuring through this professional agency they confer indirectly substantial financial aid on the funds of medical charities. The amount the agency is able to distribute annually steadily increases as the number of individual members of the profession who insure through it increases. Down to the end of 1916 it had distributed £2,405; at the end of 1917 the amount had risen to £3,405. The amounts paid over in 1917 were to the Royal Medical Benevolent Fund, £300; Royal Medical Benevolent Fund Guild, £200; Epsom College Benevolent Fund, £200; Royal Medical Benevolent Fund Society of Ireland, £40; St. Anne's School for Girls, £50. The total of £1,000 in 1917 is made up by a contribution of 200 guineas to the War Emergency Fund of the Royal Medical Benevolent Fund. Full particulars will be supplied to those interested if they will communicate with the Secretary of the Medical Insurance Agency, 429, Strand, London, W.C.2.

TRENCH FEVER.

THE etiology of trench fever is still obscure, but there is no doubt that it is of an infective nature and that the infection can be transmitted from one person to another. Inquiries into its nature were instituted a couple of years ago; they are still in progress, and it is recognized that it may be imported into this country. The most authoritative paper on the disease is that published in this JOURNAL on February 12th, 1916 (vol. i, p. 225) by McNee, Renshaw, and Brunt. They showed that it can be transmitted from one person to another by whole blood, whether injected intravenously or intramuscularly, but as to how the disease is transmitted in nature there is as yet no definite evidence. The facts seem to point to the conclusion either that it is contagious from man to man, or, what seems more likely, is carried by some common fly or parasite; there is considerable reason for incriminating the louse. Two clinical types of the disease are distinguished, the one a short fever of about a week's duration, followed frequently after a few days by a short single relapse, and the other a longer illness characterized specially by the number, sharpness, and periodicity of the relapses, as is well shown in some of the charts illustrating the paper to which we have referred. In both forms the onset is sudden, sometimes extremely abrupt. The only constant symptoms are headache, especially behind the eyes, followed soon by pain in the legs (trench shins) and in the small of the back. It is practically certain that the two clinical forms are due to the same infection. The incubation period varied from six days in one of the experimental transmissions reported in the paper to twenty-two days. The virus would appear to be contained within the blood corpuscles themselves, whether leucocytes or red cells. The diagnosis is difficult, and at first the cases were considered to be influenza. Trench fever is to be distinguished from influenza mainly by the character of the temperature chart, but also by the bone pain, which is commonly present in the shins but occasionally occurs in other bones, and by the general absence of any catarrhal affection of the air passages. There is some reason to suspect that this disease is the sweating sickness of the old writers, which broke out among the armies in Flanders at the beginning of the eighteenth century. There is strong evidence that the disease was imported into the armies at or near Salonica by troops coming from France, and it is thought possible that the infection may reach this country, or, indeed, that cases may have already occurred among persons brought into close contact with soldiers returned. We, in fact, published two short notes on February 17th, 1917, pp. 221, 222, by Captain R. D. MacGregor, I.M.S., and Captain Jeffrey

Ramsay, R.A.M.C.(T.), in which they described cases they considered to be trench fever, occurring in one instance in a private R.A.M.C., and in others in men from a camp in the north of England. If any of our readers have come across cases which, while presenting a general resemblance to influenza, differ from it in the respects mentioned, brief records will be useful to the inquiry now in progress; they may be sent to Surgeon-General Sir David Bruce, C.B., F.R.S., Chairman, Trench Fever Committee of the War Office, at the Royal Army Medical College, Grosvenor Road, London, S.W.1. The disease might be looked for among the children of soldiers who have been at home on leave from the front.

ADDISON'S DISEASE AND THE WAR.

THE strain of war on the ductless glands has attracted much attention, and hyperthyroidism and later overactivity of all the endocrine glands have been described. As a late result of extreme hypertrophy atrophy is recognized, and clinically Graves's disease may be succeeded by myxoedema; possibly by an analogous process, or perhaps, as F. Ramond and R. François¹ suggest, as the result of overfatigue or of various infective or toxic influences the adrenals falling an easier prey to tuberculosis, Addison's disease is becoming commoner. These authors state that since May, 1917, no fewer than 26 cases of this rare disease have been under their observation. The patients were about 30 years of age, and had been a long time at the front, and therefore much exposed to stress and emotions exciting the adrenals to overactivity. Among the 26 cases 12 were regarded as fully developed cases and 14 as *fruste* or incomplete cases, four of the latter showed hyperthyroidism, and, though the authors would not agree to the view that this diagnosis is sufficient, it therefore appears advisable to exclude them. But even so, 22 cases of Addison's disease in six months is an unheard of experience. A remarkable feature about Addison's disease in war is stated to be that the arterial blood pressure is well maintained until near the fatal termination. All the cases except the four it is proposed to exclude went downhill.

THE WORK OF THE MEDICAL RESEARCH COMMITTEE.

WE have announced the publication of the third annual report of the Medical Research Committee, and have referred on more than one occasion to some of the facts it contains, and may now note some other points. The Mount Vernon building at Hampstead, acquired to serve as the home of the Central Research Institute, was lent by the Committee in 1914 to the War Office for hospital purposes. Early in 1916 it was set aside for the investigation and treatment of cardiac disorders in soldiers. In particular, research was carried out under the direction of Dr. Thomas Lewis into the condition known for military purposes as "D.A.H." (disordered action of the heart), and a memorandum on this subject by Dr. Lewis and his colleagues was published in the *JOURNAL* of September 23rd, 1916. In February last the results of investigations up to that date were summarized in a special report issued by the Committee; the purpose of this report, as we pointed out at the time, was to make available without delay such information upon the pathology and symptomatology of D.A.H., and the best methods of dealing with the cases, as might be of value to the services, and in the selection and training of recruits. During September last the work of the hospital was removed by the War Office from Hampstead, and established at Colchester upon a larger scale. The Mount Vernon buildings and grounds have now been assigned for the use of the Air Board as a hospital for officers of the Royal Flying Corps and the Royal Naval Air Service, and for the study and treatment of the special disabilities due to flying. The report gives

brief accounts of the work of the five departments of the Central Research Institute—bacteriology, biochemistry and pharmacology, applied physiology, statistics, and clinical research. Of the schemes framed by the Committee before the war, some only have been continued in whole or in part. The difficulty in replacing laboratory workers and attendants absent on military service has entailed much laborious routine work even of a menial kind upon the scientific men remaining. Nevertheless, progress has been made with certain grouped researches, including those into the pathology of rickets, and into certain aspects of tuberculosis. Of the other peace-time researches which have been maintained may be mentioned inquiries into the hygienic relations of milk carried out at Birmingham and Reading. But, generally speaking, the main resources of each of the scientific departments of the Central Research Institute have been devoted to special war work. An account is given of the large amount of work undertaken by the Committee in the collection and classification of army medical statistics. The extent of the undertaking may be gathered from the fact that the clerical staff employed upon this task at the British Museum now numbers more than 100. In a memorandum submitted to the Army Council in December, 1916, the Committee proposed that the War Office should bear the actual cost of the routine clerical work, while the Committee should still supply the staff and other resources of its statistical department; this proposal was adopted as from January 1st last. The memorandum pointed out that the card index being compiled by the Committee will have a national importance beyond its military and medical value, since it will provide assistance of a kind not otherwise obtainable for the proper settlement of claims for pensions or allowances. The vast series of records now being collected, classified, and stored in an accessible form will constitute the basis of the statistical handling of the medical history of the war, both for military and scientific purposes; and it will further provide a permanent national register of persons wounded, injured, or ill as a result of military employment during the war. But the value of the work for both purposes is, of course, entirely dependent upon the completeness and accuracy with which the documents concerning patients are compiled in military hospitals. Whilst on this subject, the Committee hints that the records of many home military hospitals leave much to be desired. The system in France has, however, been reorganized with better results, and the index card of the Medical Research Committee, together with the new army field medical card, represent a great advance in the direction of simplification and accessibility of clinical facts.

VOLTAIRE AND MEDICINE.

SOME books never become antiquated or their message stale and commonplace; but their authors are most exceptional, for learning, logic, and clear sight into the future—not very common properties even alone, and rare indeed in combination—are hardly enough to ensure immortality without some attraction such as wit or style. There are few better examples of such an immortal than Voltaire, whose relation to medicine has been appreciatively sketched by Dr. Pearce Bailey¹ of New York. Like other branches of science, medicine owes much to Voltaire's advocacy of *fréedom* from the oppression of fanaticism, tradition, and pretence; he was a sworn enemy of quackery, and certainly did not underestimate its prevalence when he said: "Molière made no mistake in ridiculing physicians, for, for a long time, out of every hundred doctors ninety were quacks." But in spite of its contemporary sterility, he was a loyal defender of medicine and its worthy followers, and continued: "It is just as true that a good doctor can often save life and limb. Men who pass their lives restoring

¹ F. Ramond and R. François, *Bull. et mém. Soc. Méd. des Hôp. de Paris*, 1917, 3^e sér. xli, 1001-1003.

¹ P. Bailey: *Annals of Medical History*, New York, 1917, i, 56-72.

health to others would be superior to all the great ones of the earth, and would resemble divinity." He sent charming verses to J. B. Silva, "who in mastering death has like a god behaved," and to A. M. Tronchin, who did so much to introduce inoculation against small-pox into France. Voltaire vigorously advocated this prophylactic measure, and, when it was opposed and the Paris parliament referred the question of its value to the faculties of theology and medicine, wrote: "You gentlemen, who are the best theologians and the best physicians in Europe, should issue an injunction against small-pox, just as you have against Aristotle's categories, the circulation of the blood, emetics, and quinine." He was much interested in syphilis, or the grand-pox as he called it, distinguished it from leprosy, gave reasons still used at the present time for believing that it came from America, and urged the need for a whole-hearted crusade to stamp out this enemy of all humanity. Thus, much of what he wrote on medical subjects applies to the present day; he anticipated the prophetic teaching that made Pinel immortal as the saviour of the insane, and urged sanitary reforms in the overcrowded Hôtel-Dieu in Paris. Although medical subjects form a comparatively small portion of his extensive works, he unerringly picked out the truth from the conflicting medical systems of his day, and had an accurate knowledge of its scope and terms.

COLD AFFUSION IN FEVER.

SOME time ago Mr. George Alexander, of Cardiff, kindly sent us a copy of a letter by William Salmon, a surgeon of Cowbridge, published in the *Cambrian* of September 20th, 1817. The writer states that as the beneficial effects of the external application of cold water in typhus fever were little known in that part of the country, he thought it would be useful to give publicity to a case in which he employed it successfully. On September 5th he was called to a labourer in the sixth day of the illness, whose symptoms were most alarming. The man had been delirious throughout the preceding night, and at times was so unmanageable that it required two men to keep him in bed. The pulse was 120 to 130, the tongue was parched, dry, and covered with a brown crust, the skin hot and dry, the eyes wild and inflamed, the hands constantly in motion picking the bed-clothes and other things about him; he muttered and talked incoherently to himself. Mr. Salmon, determining to try cold affusion, had him placed upon a stool supported by two men. A third stood on a chair behind him and poured a large pan of cold water fresh from the well over his head and body. He was then wiped dry and immediately put back into bed. In less than ten minutes he became perfectly tranquil, his pulse fell to under 90, he answered correctly every question put to him, and the delirium and other unfavourable symptoms left him. The next morning it was found he had passed a good night, with a gentle perspiration during the whole of it; from that time the fever gradually abated, and at the date of writing he had quite recovered. We give the principal points in Mr. Salmon's letter, as our correspondent states that he sent it at the suggestion of Lieutenant-Colonel Rhys Griffiths, R.A.M.C., of Cardiff, and it is interesting to find such a letter in a lay paper a hundred years ago, but cold affusion was, even in 1817, no new thing. James Currie, in his *Medical Reports*, published in 1797, says¹ that by the judicious application of this treatment fever was generally arrested in its onset or mitigated in its progress and finally subdued. Currie made no claim to be the originator of the method. As early as 1768 it was introduced in the West Indies by Dr. William Wright, of Edinburgh, whose account of his practice was made public in the *London Medical*

Journal for 1786. The use of cold water in febrile affections was familiar to the ancients. Hippocrates recommended it in arthritis and dysentery. Antonius Musa, a young Greek physician, saved the life of Augustus when he was suffering from hepatitis by means of cold baths and drinks. He probably got the idea from his master Asclepiades, who was called the giver of cold water. To Currie, however, are due the first specific directions for the safe application of cold affusion. He was also the first medical writer who insisted on the necessity of thermometric observations in febrile diseases as a guide in their treatment, and under his direction small mercurial thermometers with a movable scale were made for clinical use. No notice was taken of Wright's paper for several years, till at the end of the eighteenth century Gregory of Edinburgh tried cold sponging in fevers with great success. The practice, says Wright, in a letter to Currie written in 1799, was talked of among the students, but adopted by very few of the Edinburgh physicians. It came gradually into use in the United Kingdom, except in London, where for the most part it was received with indifference or disapproval. In the services it found special favour. Currie says that on the whole his endeavours had been successful, and he had encountered little opposition. The water treatment was successfully extended by him to scarlet fever, measles, eruptive small-pox, and many complaints of childhood. He used tepid water when the debility seemed too great to warrant the application of cold. He also found that the shock of the cold affusion was frequently a powerful remedy in tetanus and other convulsive disorders. Currie was a son of the manse, and was born at Kirkpatrick Fleming on May 31st, 1756. He studied medicine at Edinburgh, where he attracted the attention of Cullen, and established himself at Liverpool, where he became very prominent not only as a physician but as a citizen and a political writer. He also gained a considerable literary reputation as the biographer of Robert Burns.

VENEREAL DISEASES.

THE second report of the National Council for Combating Venereal Diseases¹ shows that between June, 1916, and June, 1917, the educational campaign undertaken by the Council made considerable progress, not only in Great Britain, but also in the overseas dominions. A strong branch has been formed in South Africa, and communications have been opened with Canada, Australia, and New Zealand, with the object of forming similar organizations in those dominions. In England the educational work has consisted in giving publicity to the facilities for free diagnosis and treatment in those areas where such provision is made, and in stirring up backward localities to establish facilities. When the Local Government Board informs the Council that a treatment scheme has been approved in any area, the machinery of the Council is placed at the disposal of the local authorities for the purpose of organizing a local educational campaign through the medium of a branch. Such branches have been established in fourteen towns during the year; in Cambridge there is a county committee and there are branches in Ulster and Glasgow. It is noted with regret that a certain number of counties and county boroughs have not yet taken any steps towards providing educational facilities. The action taken by the British Medical Association and the Council to secure legislation making it a penal offence for any person other than a qualified medical practitioner to treat venereal disease has been successful. At the request of the Director-General of the Army Medical Service many lectures were given to soldiers under the auspices of the Council, but much more could be done in this direction if more medical men were available. With regard to the subject of artificial prophylaxis, which was

¹ *Memoir of the Life, Writings, and Correspondence of James Currie, M.D., F.R.S., of Liverpool*. Edited by his son, William Wallace Currie. London, 1831. Vol. i, p. 213 et seq.

¹ London: The National Council for Combating Venereal Diseases, Avenue Chambers, Southampton Row, W.C.1. Price 6d.

brought into prominence through correspondence in the *BRITISH MEDICAL JOURNAL* and elsewhere, it was felt that the Council should define its attitude. The Executive Committee, after considerable discussion, decided that it was undesirable for the Council to take steps in the direction of a campaign in favour of prophylactic teaching. Subsequently the committee passed the two following resolutions expressing the attitude of the majority of those present: (1) That a distinction can be drawn between prophylaxis and early treatment; (2) that at present at least it would be unwise for the National Council to go beyond the proposals of the Royal Commission. The report contains a full account of the second annual meeting held on June 13th, 1917, together with reports of branches and the text of the Venereal Disease Act, 1917.

NATIONAL INSURANCE AND ATTENDANCE ON DEPENDANTS.

THERE is expectation that before this issue is printed the National Health Insurance Amendment Bill will have been passed through the House of Commons, and no great changes in it are likely to be made in the House of Lords. In these circumstances there is every probability that the measure will be placed on the Statute Book before the session is wound up at the end of January or in February. The idea seems to have got about in the Lobby that the Insurance Commissioners contemplated seeking fresh powers under the bill, so as to enable them to embark upon a scheme for medical benefit for the dependants of insured persons. Such a proposal would have gone far beyond what is submitted as an amending measure and nothing more, that is, a measure to vary and improve existing arrangements. It is within common knowledge, however, that an extension of National Insurance on the lines mentioned has its advocates, especially amongst the Insurance Committees. The medical profession would therefore be wise to recognize that some effort may be made to bring forward a project of the kind in the coming session. Assuming that the informal conferences that are understood to be taking place in regard to the framing of a constitution for a Health Ministry do not mature in time for a bill for this purpose to be submitted next session, it is almost certain that Mr. Hayes Fisher will introduce a bill to give the English Local Government Board powers somewhat akin to those already possessed by the Scottish and Irish Local Government Boards in regard to child welfare. These would not, however, be quite the same; the conditions differ. But it may happen that this measure, having for its object fresh provisions, may prove larger in its scope than is at present suggested. Anyhow the matter is one that should be watched.

DISABLED COMBATANTS AND THE FUTURE OF THE RACE.

THE scale of pensions awarded to disabled soldiers and sailors has an important bearing from the eugenic point of view. The permanent men in the navy and army are a picked body, and, though there are many exceptions, the men serving for the period of hostilities were, as a rule, in better physical health than those who remained at home; and, further, the combatants, especially the volunteers, are endowed with mental qualities that should be perpetuated in future generations. There is, therefore, something to be said in favour of so providing for the injured combatant that he should be able to have children. Pensions or compensation are allotted to all disabled men, and, in addition, certain small allowances may be made for each child born of a marriage contracted before the man's discharge. But to the disabled bachelor combatant, as Major Leonard Darwin¹ points out, the State in effect says: "Marry or not, just as you please, but

mind you don't have any children." On racial grounds the statutory commission should have powers to make special grants for educational purposes in order to enable post-war children to be brought up more nearly as they would have been had the father not been injured. Allowances of this kind would necessarily have to be guarded both from improper use and from the risk of propagating hereditary disease, and on the last point medical men would give valuable advice. Wounded men's children would receive this additional assistance without question, but the children of men who enlisted with constitutional defects or were invalided for venereal or tuberculous infection would be on a different footing. It would be advisable to introduce into the official "medical reports on invalided soldiers" some question as to the existence of any family or personal factor which could bear on the disability necessitating discharge. A remarkable example of anomalies of pensions in America was quoted in the discussion of the paper by Mr. W. Howard Hazel, who stated that in 1902 there were still drawing pensions twelve widows of men who fought with George Washington; and, as was noted in our columns in an account of the United States pension system published last year, pensions were still being paid in 1915 to 134 widows in respect of the war of 1812. The explanation offered is not that the longevity of American women is unusual, but that old soldiers of 80 were often married by young women for the sake of the pension they would receive so long as they did not remarry.

THE PSYCHICAL FACTOR IN THERAPEUTICS.

PARAPHRASING Boileau it may be said that:

Tel donne à pleines mains qui ne guérit personne
La manière de donner vaut mieux que ce qu'on donne.

The "manière de donner" counts for a good deal in the treatment of disease. The fact is, all methods of treatment, unless it be the 5 grains of calomel every Saturday night, if they are to prove successful, must comprise a certain dose of "suggestion," a factor the importance of which is perhaps not always sufficiently present in the mind of the prescriber. The more protracted the course of treatment the more imperative the necessity for the maintenance of hopeful expectancy, and this can only be achieved by varying the nature of the drug or the manner of its exhibition at regular intervals. In treating a patient suffering from such a disease as chronic pulmonary tuberculosis, for instance, it is often advisable to vary the prescription every three weeks or so. This presents no difficulty, because remineralizing agents, for example, are legion, and all we have to do is to select an alternative. During one period special attention can be directed to the pulmonary symptoms; during the next period we may seek to improve the general health without, on that account, neglecting the air passages; while during a third period our efforts may be concentrated on diet and digestion. Then, too, the method of administration should be changed from time to time. The exhibition of drugs by the mouth can be discarded in favour of hypodermic, intramuscular, or even intravenous medication, a plan which has the incontestable advantage of giving the stomach rest. Preparations of malt can be alternated with cod liver oil, and the latter can be prescribed in half a dozen different forms. By "ringing the changes" in this way it is possible, without any interruption of the course of treatment, to keep alive in the patient's bosom the spark of hope which alone will continue to render him amenable to the "suggestion" that emanates from every medical adviser who knows his business. This plan of campaign is equally applicable in chronic diseases such as diabetes and cardio-vascular affections: it is, indeed, of special value in the latter class of malady owing to the physical and mental depression with which they are associated. As a matter of fact, the cardio-vascular subject takes a lot of bucking up in contrast with the pulmonary

¹ *The Eugenics Review*, 1917, ix, 1-17.

patient, who only asks to be allowed to practise self-deceit, and is grateful to his doctor for providing the means.

THYMIC DWARFISM.

THE insight recently acquired into the significance of the ductless glands in relation to growth has given a new impetus to the study of dwarfism. Dr. K. H. Krabbe¹ has recently published a case of dwarfism, which he traces to some disorder of the thymus. The patient was a girl born in 1899. When she was admitted to hospital in 1914 myxoedema was diagnosed; then she was demonstrated as a case of pluriglandular insufficiency manifested as progeria. Later this diagnosis was questioned, as the progeria of Hastings Gifford—only a few cases of which have been described—is characterized by senility and a debility not noticeable in this case. There was no family history of interest. She weighed 3.75 kilos at birth, and was breast-fed for the first year. The first tooth appeared in the ninth month, and she began to walk at the age of eighteen months. At this age she was bow-legged, but in spite of this she walked well at the age of 2. Mentally she was, if anything, forward; she attended school at the age of 6. At the age of 15 her height was only 111 cm., and menstruation had not begun. Relatively to the legs, the trunk was long, but as a whole the body looked small and stunted. Her expression was lively and intelligent, and there was no sign of myxoedema in the face, which resembled that of a woman of 40. The hair of the scalp was very scanty, and consisted of fine, silky tufts of a light yellow colour. There was no hair in the axillae or on the pubes. The skin of the hands and arms was somewhat dry and desquamating, whereas there was excessive perspiration from the axillae. Pigmented patches the size of a lentil were scattered over the scalp. The thyroid gland was not enlarged, and the x-ray examination of the cranium and teeth showed no abnormality. The reproductive organs were infantile in September, 1914, but by February, 1916, they had grown appreciably, ovarian extract having been given in the interval for nearly three months. She was also treated with suprarenin and thyroïdin for a short time without any noteworthy effects. Wassermann's reaction was negative, and there was no sign of tetany. After stating that dwarfism and rickets are a constant sequel to thymectomy in various animals, the author points out other features common to these animals and his patient. Deficient growth of hair is, he says, one such feature. His diagnosis of thymic dwarfism is further strengthened by a careful investigation and elimination of the other known causes of dwarfism.

CANCER AND ENVIRONMENT IN ANCIENT GREECE.

Among the interesting articles in *Science Progress* for October there is a short scholarly essay by Mr. Harold P. Cooke of Durham University, entitled "Some historical reflections on cancer."² It is preceded by a brilliant and caustic criticism of English as she is wrote by a classical schoolmaster, from Dr. Charles Mercier's pen; both of these essays should be read, but not in the order in which they come, otherwise the reader may be led to speculate, perhaps perversely, as to the remarkable altruism of the author of the sentence: "While I cannot unfortunately pretend to more intimate knowledge of the ills of the flesh than the generality of men are heirs to, I desire in these papers to put forward some reflections on cancer." (The italic is ours.) Starting with the assurance from the Regius Professor of Physic at Cambridge that the Greek physicians of the period were familiar with cancer, Mr. Cooke tests by an analysis of Plato's works two popular British superstitions—the causation of cancer by meat,

and its special prevalence in the most thickly-wooded districts. These may perhaps not require very serious consideration, but this does not detract from the interesting way in which he arrives at the conclusion that cancer was familiar in a country very largely denuded of trees, among a people mainly subsisting on what may be called a vegetarian diet, and that the later the date assigned to the relevant Hippocratic writings, the more pronounced were the deforestation and consequent shortage of pasture and herds.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE report of the meeting of the Committee of Belgian Doctors' and Pharmacists' Relief Fund, published last week, p. 814, will have prepared our readers for the information that the Committee is about to issue an appeal for contributions to enable the work to be carried on for another year. During the whole of 1917 the Committee has been sending £800 a month to the Medical and Pharmaceutical Committee in Belgium, and it now has less than £800 in hand. The treasurer's account for the five months ending November 30th, together with the certificate of the chartered accountants and auditors, was published last week. We hope to publish the appeal in our next issue, and will only now state that the treasurer is Dr. H. A. Des Voeux, 14, Buckingham Gate, London, S.W.1.

THE HALF-YEARLY INDEXES FOR 1917.

THE usual half-yearly indexes to the JOURNAL, to the EPITOME, and to the SUPPLEMENT, have been prepared, and will be printed. They will, however, not be issued with all copies of the JOURNAL. Any member or subscriber who desires to have one or all three of the indexes can obtain a copy of what he wants post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association, 429, Strand, W.C.2. Such copies will be dispatched shortly after the middle of January.

Medical Notes in Parliament.

Service Before Qualification and Seniority After.—In the course of a short debate on December 10th on a naval supplementary estimate for officers and men (an addition not exceeding 50,000) General McCalmont raised a point as to young officers sent home to complete their surgical training. He was told that when they were subsequently offered commissions in the Royal Army Medical Corps they were refused any previous seniority. When a man had served two years in France it was rather ridiculous that he should go out again just as if he were an entirely new officer with no service whatever. He trusted he was correctly informed that the navy did give to such young men, whether they had been in the army or navy, some claim to their previous seniority. Dr. Macnamara took it that General McCalmont's question was whether certain probationers of the Royal Naval Volunteer Reserve who had been demobilized and went back to enter as temporary surgeons got seniority in respect of the probationary service. This time discount as part of the qualifying period they were bound to go through. He added that if a question were put on the paper he would give the precise facts.

Whisky in Hospitals.—On December 11th Mr. Clynes (Parliamentary Secretary to the Minister for Food) said that arrangements had been made for additional supplies of whisky to be provided for hospital patients where the application was accompanied by a medical certificate, but he feared that it would not be practicable to extend this concession to invalids generally.

Enteric Fever in the Army and Navy.—Mr. Chancellor asked how many of the 893 cases of enteric fever referred to in the Local Government Board's Report for 1916-17 were naval; how many of these were inoculated; and how many fatal. Dr. Macnamara replied that the number of cases of enteric fever in the navy in this country during the period referred to—that is, April 1st, 1916, to March 31st, 1917—was 40. One of the patients had been inoculated and survived; 9 cases proved fatal. In reply to a similar question in regard to military cases, Mr. Macpherson said that the information was not available.

THE WAR.

GENERAL PRINCIPLES OF THE TREATMENT OF WOUNDS OF WAR.

AN interallied surgical conference attended by delegates from England, Belgium, France, Italy, Japan, Portugal, and Serbia, was held in Paris in March and May, 1917, and subsequent conferences have been attended by delegates from the United States and Russia. The conclusions adopted at the earlier conference were published in French last April, and a translation¹ of those adopted both in March and May has now been published. The first paragraph lays it down that the organization of the medical service should provide for continuity in the treatment of the wounded. The work of the conferences has been largely directed towards the detailed application of this general principle.

On certain points the views have advanced to some extent since the spring, but, speaking generally, the doctrines advocated are identical with those now and for long followed in the British armies in the field, and we propose to note only a few points.

It is advised that patients should be transferred as quickly as possible to casualty clearing stations situated between 11,000 and 22,000 yards (6 to 12 miles) from the front, special operating stations being pushed further forward when required, the surgical attention they receive meanwhile being reduced to a minimum.

The primary closure of wounds is held to be justifiable only when not more than eight hours have elapsed since their infliction, and when circumstances allow of the patient remaining under the observation of the same surgeon for as many as fifteen days. Secondary closure may be performed when clinical sterility of the wound appears to be reached. This should be judged by examination of the discharges in a well equipped bacteriological laboratory. Such a laboratory should be attached to every surgical unit of importance, and the surgeon should do his work in association with the officer in charge of it.

Stress is laid on the necessity of all surgeons having at hand means of discovering and accurately localizing foreign bodies. In front line hospitals x-ray screening methods, and in base hospitals radiograph methods, are considered the most suitable for use.

The exact character of the soil of the locality in which the fighting is taking place is mentioned as having a considerable influence on the frequency with which cases of gas gangrene occur, and the risks of its actual development are shown to diminish in direct proportion to the promptitude and efficiency with which surgical measures are carried out.

The teaching in regard to these measures is in general accordance with current practice, though it does not appear to include an allusion to the important fact that gas gangrene may often be arrested by tracking up an affected muscle right to its insertion, and removing it in its entirety. The paper in which this important circumstance was first made public, by Cuthbert Wallace and his co-workers, appeared in the *BRITISH MEDICAL JOURNAL* last June (p. 725). In cases of gas gangrene for which amputation is deemed imperative, the flush method is advised.

The prevention and treatment of traumatic shock is discussed in considerable detail, much stress being laid on precise observation of the blood pressure. Intravenous injections are advised, but the one mentioned as the best to use (Locke's liquid) is more complicated in its composition than that which recent investigations on our own side in France, and by the Shock Committee in London, appear to have shown to be necessary. In severe cases of true shock without haemorrhage any long operation that may be required must be deferred until the patient has to some extent recovered. Operation should not, however, be deferred when the only procedure in view is a rapid amputation.

Apart from fulminant gas gangrene, the indications for primary amputation are mainly pulverization, crushing, or partial avulsion of a limb, and, especially, rupture of its main blood vessels. The chief indication for secondary

amputations is massive gangrene, either ischaemic or infective, and for late amputations chronic infection and cachexia which does not respond to any form of treatment. In primary amputations the wound should be left widely open, and its situation should correspond as closely as possible with the site of the fracture, the soft parts being simply divided and the bone trimmed or rounded off if necessary. In late amputations the surgeon must be guided by prosthetic considerations, which are considered in detail.

In the section on treatment of fractures stress is laid on the importance from the very beginning of immobilization, to be followed eventually by immobilization *plus* mechanical extension. The best splint is stated to be the Thomas, and all the splints recommended conform to the Thomas principle. Definite immobilization is necessary; the apparatus chosen should allow extension, abduction, and flexion of the limb (splints of the Thomas type; suspension apparatus, such as Sinclair's or the Anglo-American; the apparatus of Delbet or Alquier). Delbet's apparatus allows the patient to walk at a very early date. Nothing is said as to the difficulty of treating compound fractures of the thigh in the neighbourhood of the tuberosity, by any existing splint.

The combination of circumstances which makes it legitimate to attempt the primary closure of a wound leading down to a fractured bone is shown to be rare. Treatment of joints and of arterial injuries is also considered, and it is clear that in regard to the first subject opinion was not unanimous.

Separate sections are devoted to injuries of the nerves, the spinal cord, and wounds of the brain. In head operations local anaesthesia is advised. Cases which have undergone trephining should not be moved under three weeks. Cases in which the dura mater is intact should be left alone. Attempts to remove very small projectiles difficult of access, or large projectiles lying at the base of the skull, or in the ventricles, or in the opposite hemisphere, are not advised as part of any primary operation. The debated question of the treatment of sinus injuries is not mentioned.

With certain exceptions—that is, when the injury is definitely limited to liver or kidney, and there are no symptoms of severe haemorrhage, or when the patient has not come under treatment within thirty-six hours after he has been wounded—laparotomy should be systematically practised.

The section on chest wounds indicates that the surgeons present at this conference were not disposed strongly to favour primary surgical interference in the majority of cases.

The record also includes a note on the desirability of further search being made for antiserums against gas gangrene organisms. Apart from surgical cleansing, the only wound treatments mentioned are Carrel-Dakin solution and the preparation advised by Morison (bipp). The value of both is indicated.

GASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

CAPTAIN J. A. EDMOND, R.A.M.C.

Captain John Adamson Edmond, R.A.M.C., was killed in action on December 1st. He was educated at Guy's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1910, and graduated M.B., B.S. Lond. in 1913. After acting as house-surgeon, obstetric resident, and resident medical officer of Bright ward at Guy's, he went into practice in partnership at Catford, also holding the appointment of chief clinical assistant in the ear and throat department at Guy's. He took a temporary commission as lieutenant in the R.A.M.C. in the middle of 1916, and was promoted to captain after a year's service.

CAPTAIN J. N. GRIFFITHS, R.A.M.C.

Captain John Neville Griffiths, R.A.M.C. was killed in action on November 30th, aged 36. He was the son of the late G. Neville Griffiths of Sydney, and of Woorcoowolgen, Casino, Australia, and was educated at Sydney University, where he graduated M.B. in 1905 and Ch.M. in 1911. After filling the posts of resident medical officer of the

¹ H.M. Stationery Office. Price 2d. net.

Women's Hospital, Sydney, and of junior resident medical officer of the public hospital at Perth, Western Australia, he came to England, took the D.P.H. of the London Colleges in 1910, and was appointed honorary assistant physician to the Chelsea Tuberculin Dispensary. He took a temporary commission as lieutenant in the R.A.M.C. on December 1st, 1914, and was promoted to captain after a year's service.

CAPTAIN J. M. MATHESON, R.A.M.C.

Captain James Macdonald Matheson, R.A.M.C., was killed in action on November 30th, aged 29. He was the youngest son of the late William James Matheson of Newton, Novar, Ross-shire, and was educated at the Edinburgh Institution and at Glasgow University, where he graduated M.B. and Ch.B. in 1916. He took a temporary commission as lieutenant in the R.A.M.C. after qualifying, and was promoted to captain after a year's service. He had served for six months in the navy, also in Mesopotamia and in France, and was attached to the Middlesex Regiment when killed.

CAPTAIN C. H. ROBSON, R.A.M.C.

Captain Charles Henry Robson, R.A.M.C., killed in action on December 2nd, was the eldest son of Mr. Alfred Robson of Whitley Bay. He was educated at Newcastle-upon-Tyne and graduated M.B., B.S.Durb. in 1913. He took a commission in the R.A.M.C. soon after the outbreak of war, and saw service in Gallipoli from June, 1915, to August, 1916, and in France from August, 1916, until his death. He leaves a widow.

Died in Service.

CAPTAIN W. J. CORRIDON, I.S.M.D.

Captain William James Corridon, Indian Subordinate Medical Department, was reported as having died on service (probably in Mesopotamia) in the casualty list published on December 14th. He was born on May 29th, 1868, entered the I.S.M.D. from the Calcutta Medical College in 1886, was promoted to the rank of lieutenant and grade of senior assistant surgeon on November 22nd, 1911, and had attained the rank of captain during the war. Before the war began he was in civil employment in the United Provinces, where he held the post of deputy superintendent of the Agra lunatic asylum.

Wounded.

Captain T. F. Craig, R.A.M.C. (temporary).

Captain C. O'Malley, R.A.M.C. (temporary).

Captain W. Robertson, R.A.M.C. (T.F.).

Captain J. M. Robins, R.A.M.C. (T.F.).

Captain A. Stewart, R.A.M.C. (temporary).

Lieutenant R. A. Hosegood, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Harker, George Cuthbert Warburton, Captain London Regiment, younger son of Dr. T. Harker of Bournemouth, late of Sydenham, died of wounds in hospital abroad on December 1st, aged 27. He got his first commission on April 9th, 1915, as second lieutenant in the 12th (County of London) Territorial Battalion of the London Regiment (the Rangers).

Morse, Christopher, Lieutenant Royal Engineers, youngest son of Mr. Thomas H. Morse, F.R.C.S., of Deal, killed December 7th, aged 25. He was born at Norwich in 1892 and educated at Norwich Grammar School, at Haileybury, and at Pembroke College, Cambridge. He got his first commission in the Buffs on September 14th, 1914, and transferred to a tunnelling company of the Royal Engineers in 1915. He had been recommended for the Military Cross.

Naylor, Eric Lewis, Lieutenant South Staffordshire Regiment, elder son of Major A. T. Naylor, R.A.M.C. (T.F.), of Eltham, S.E., killed December 3rd, aged 19. He was educated at Merchant Taylors' School and at London University, where he was in the O.T.C., got his commission in June, 1915, and went to the front in June, 1916.

Reid, Leslie, Second Lieutenant Dragoon Guards, third son of the late Dr. W. S. Reid of Oakley, Kircudbright, killed recently, aged 20. He was educated at Dunstable Grammar School.

Stewart, Vernon R., Lieutenant Royal Flying Corps, elder son of Dr. J. Stewart of Haslingden, recently killed accidentally while flying. He got his first commission in the Army Service Corps on March 12th, 1915.

Taylor, Ian Cleasby, Second Lieutenant Royal Scots, eldest son of Dr. Cleasby Taylor of Berwick-on-Tweed, killed December 4th, aged 21. He was educated at Watson's College, Edinburgh, and before the war was studying engineering in Armstrong's works, at Newcastle-on-Tyne. Enlisting in the Northern Cyclists at the beginning of the war, he got a commission in 1915, and went to the front in October, 1916.

MEDICAL STUDENT.

Boyd, Gavin Hadow, Second Lieutenant King's Royal Rifles, killed in action on December 2nd, aged 19. He was the only son of Mr. Samuel Boyd of Maybole, and was educated at the Maybole Grammar School and Glasgow University, where he was a second year medical student when he joined up.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SPECIAL Supplement to the *London Gazette*, issued on December 17th, contained a list of awards for gallantry and distinguished service in the fields. The acts of gallantry for which the decorations have been awarded will be announced in the *London Gazette* as early as practicable. The list contains the following medical officers who receive the awards indicated:

Bar to the Distinguished Service Order.

Temporary Captain (temporary Lieut.-Colonel) Charles Derwent Pye-Smith, D.S.O., M.C., M.B., F.R.C.S., R.A.M.C. (D.S.O. gazetted August 16th, 1917.)

Distinguished Service Order.

Majors Eric Lloyd Hutchinson and Philip Alan Maplestone, A.A.M.C.

Captain William Henry Collins, A.A.M.C.

Temporary Captain William Howard Lister, M.C., R.A.M.C.

Bar to the Military Cross.

Captains Richard Thompson Caesar, M.C., M.D., R.A.M.C. (M.C. gazetted June 18th, 1917), Cyril Jacobs, M.C., M.B., R.A.M.C.S.R. (M.C. gazetted July 18th, 1917).

Temporary Captains John Maitland Forsyth, M.C., R.A.M.C. (M.C. gazetted September 22nd, 1916), David Henry Russell, M.C., M.D., R.A.M.C. (M.C. gazetted August 16th, 1917), Philip Randal Woodhouse, M.C., M.B., R.A.M.C. (M.C. gazetted May 31st, 1916).

Military Cross.

Temporary Surgeon Richard Glyn Morgan, R.M. Battalion.

Captains: Matthew Thomas Ascough, R.A.M.C.; Hartas Foxton, R.A.M.C.; Reginald Douglas Gawn, M.B., R.A.M.C.; Norman Bell Graham, M.B., R.A.M.C. (S.R.); William Baly Jepson, R.A.M.C. (S.R.), attached Devon Regiment; Frederick William Lumsden, N.Z.M.C.; Duncan Macfadyen, R.A.M.C. (S.R.); John McGhie, N.Z.M.C.; James McKay, M.B., R.A.M.C. (S.R.), attached Bedford Regiment; Hugh Agnew Macmillan, M.B., R.A.M.C.; John Pinder, R.A.M.C.; William Jack Scade, M.B., R.A.M.C., attached Highland Light Infantry; Samuel Llewellyn Serpell, N.Z.M.C.; Charles Nixon Smith, M.B., R.A.M.C.; Walter Leonard Smith, A.A.M.C.; Robert Fowler Walker, M.B., R.A.M.C. (S.R.).

Temporary Captains: Everard Cecil Abraham, M.B., R.A.M.C.; William Robert Addis, M.B., R.A.M.C.; Arthur Cecil Barker Biggs, R.A.M.C., attached Suffolk Regiment; George Alexander Birnie, M.B., R.A.M.C.; Robert Briffault, R.A.M.C., attached York and Lancashire Regiment; George Edwin Chissell, R.A.M.C.; Edward James Clark, M.B., R.A.M.C., attached South Staffordshire Regiment; Frederick Pearson Fisher, M.B., R.A.M.C.; Alistair Gordon Forbes, S.A.M.C.; Charles Leslie Grove Powell, R.A.M.C., attached East Surrey Regiment; William Steadman, R.A.M.C.; Frederick Naylor Stewart, M.D., R.A.M.C.; Norman Charles Talbot, M.B., R.A.M.C.; Henry Currie Watson, M.B., R.A.M.C.

Lieutenants: Robert Hector Baxter, N.Z.M.C.; Arthur Robert Hill, M.B., R.A.M.C. (S.R.), attached Gloucestershire Regiment.

Temporary Lieutenants (temporary Captains): William Leonard Eliot Reynolds, R.A.M.C.; Robert Ievers Sullivan, M.D., R.A.M.C.

Temporary Lieutenants: Charles Herbert Booth, R.A.M.C.; Arthur Philip Draper, M.D., R.A.M.C.; Robert Everard Whitting, M.D., R.A.M.C.

One private each of the R.A.M.C. and A.A.M.C. receive a bar to the Military Medal; 7 non-commissioned officers and 40 privates of the R.A.M.C., 8 N.C.O.'s and 22 privates of the A.A.M.C., 6 N.C.O.'s and 10 privates of the N.Z.M.C., and 1 N.C.O. and 1 private of the S.A.M.C. are awarded the Military Medal for bravery in the field. The Meritorious Medal for gallantry in the performance of military duty, and in recognition of valuable services rendered with the armies in the field has been bestowed upon 9 N.C.O.'s and 1 private of the R.A.M.C. and 1 N.C.O. of the C.A.M.C.

FOREIGN DECORATIONS.

The King has granted unrestricted permission to the following medical officers to wear the decorations indicated conferred upon them by the President of the French Republic.

LEGION D'HONNEUR.

Croix de Commandeur.

Surgeon General Sir Hayward Reader Whitehead, K.C.B., F.R.C.S., A.M.S.

Croix d'Officier.

Colonel Stephen Frazer Clark, M.B., R.A.M.C.
Lieut.-Colonels Francis John Brakenridge, C.M.G., R.A.M.C.
Herbert John Martin Bulist, D.S.O., M.B., R.A.M.C.

Croix de Chevalier.

Captain William Lombard Murphy, R.A.M.C.

Croix de Guerre.

Captain (acting Lieut.-Colonel) Alexander Donald Fraser,
D.S.O., M.C., M.B., R.A.M.C.
Temporary Lieutenant William Erling Ord, M.D., R.A.M.C.

The decoration awarded to Lieut.-Colonel Albert Edouard Le Bel, C.A.M.C., announced in the *London Gazette* of June 2nd, 1917, should read, *Croix d'Officier (Légion d'Honneur)*.

England and Wales.

"SERVICE PATIENTS" IN ASYLUMS.

In a circular dated December 12th, on arrangements for the care of sailors and soldiers disabled by mental disorder, the Local Government Board states that, after consultation with the Ministry of Pensions, the Board of Control has issued instructions for the special classification and treatment of cases of this kind. Where a sailor or soldier is discharged directly to an asylum he will, from the date of his admission, be classed as a private patient, and the cost of his maintenance will be paid by the Ministry of Pensions. It will be the duty of the medical superintendent to take up at once the question of the man's eligibility to be classed as a "Service patient," and if so classed he will receive certain further privileges. Service patients will include all cases in which the malady is attributable to (that is, caused or aggravated by) war service. It will also include non-pensionable cases—that is, those in which the malady is not attributable to military or naval service, subject to the limitations (a) that the arrangement shall not extend beyond the period of the war and twelve months afterwards; and (b) that it shall not be applied to men who before enlistment had been treated in asylums. Where the union or parish to which a sailor or soldier belongs cannot be ascertained, or where a man discharged to the care of his friends becomes worse and requires asylum treatment, or where a man discharged on grounds other than those of mental disorder subsequently becomes insane, a summary reception order will have to be obtained for the man's admission into an asylum. In such cases it will be for the superintendent to take immediate action to secure the patient's classification, if eligible, as a Service patient. The proposal that Service patients should wear a semi-military uniform has been abandoned, but suitable private clothing different from that of pauper patients will be provided, and a distinctive badge will be worn on the jacket. Section 55 of the Lunacy Act, 1890, with regard to the sending of patients "on trial," will apply to these cases, but the period of trial should not exceed one month; during absence on trial a maintenance grant will be made to the patient or to his friends. Service patients will be on the legal footing of private patients, and visiting committees will have the power to discharge them. A Service patient whose discharge has been insisted upon by friends against the advice of the medical superintendent cannot on readmission be again classified as a "Service patient" without reference to the Minister of Pensions. Since the main object of the scheme is to secure the happiness and contentment of the patient and to consult the convenience of his friends, facilities will be given for the transfer of patients to the neighbourhood of their families or friends.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

A meeting of the Governors and the Council of the King Edward's Hospital Fund for London was held on December 13th, at St. James's Palace, the Speaker of the House of Commons being in the chair. It was announced that the donor of £35,000, who wished to remain anonymous until that day, was Viscount Astor, and the best thanks of the Council were conveyed to him for his generous contribution to the Fund. Including this donation and a final instalment of more than £25,560 received under the bequest of Isabella Countess of Wilton, the total general receipts for the year, less expenses, amounted to £205,781. Lord

Revelstoke, the honorary treasurer, said that it was only because of such large contributions as these that the Fund was able to face with equanimity so large a distribution as £190,000. Sir William Collins, in making the annual statement on behalf of the League of Mercy, said that the contributions from the League to the Fund had last year been raised to £15,000. Sir William Church presented the report of the Distribution Committee, of which he is chairman. In making their awards, the committee have not lost sight of the principle of helping the hospitals which have maintained or improved their position by their own efforts. While making capital grants, the Committee have continued to discourage during the war appeals to the public in aid of building schemes which are not urgent. The number of hospitals applying for grants was again 107. The grant of £5,000 to extinguish the mortgage debt on Charing Cross Hospital enables that institution to begin the new year free of debt. The Speaker, in moving the adoption of the report and awards, read a message of appreciation and encouragement from the King, whose many visits to London hospitals during the year enabled him to estimate the importance of their services to the navy, the army, and to men disabled during the war, while adequately ministering to the ever-growing demands of the civil population.

CENTRAL MIDWIVES BOARD.

A meeting of the Central Midwives Board was held on December 13th, Sir Francis Champneys presiding. Before proceeding to the business of the day the Chairman moved a resolution expressing great regret at the death of Mr. Edward Parker Young, who had been a member of the Board from its start until the end of last March. Dr. W. E. Fothergill, one of the Board's examiners for the Liverpool and Manchester centre, had forwarded criticisms by the examiners of that centre on certain questions set at recent examinations. The Board, in reply, explained the necessity of retaining the use of technical terms, and of including elementary physiology in its syllabus, but it has taken Dr. Fothergill's representations into consideration, and communicated them to the examiners in question. In reply to a letter from Dr. Barwise, M.O.H. Derbyshire, as to the practice adopted in that county in respect of the suspension of midwives, the Board expressed its hope that an understanding would be reached between the local authority and the midwives as to the mode of disinfection authorized, and that the inspector might be sent, if necessary, as soon as the infection becomes known to the authority. Seven women were removed from the midwives' roll on their own application.

RE-EDUCATION OF THE DISABLED.

At a meeting of the Royal Society of Arts on December 12th, under the chairmanship of Sir Alfred Keogh, G.C.B., Lord Charnwood read a paper on technical training for disabled soldiers and sailors. He drew attention to the hopeful fact that among this mass of damaged men there were many cases of latent capacity and character, which, when discovered, developed, and directed, would greatly enrich the life of the community. Down to the end of last September the total number of officers and men discharged from the navy and army as unfit for further service was, he said, about 225,000. While the number of palpably grievous injuries was well within the compass of the community to deal with adequately, there was a constantly growing number of men more or less enfeebled by injuries of very various kinds and uncertain extent, some of whom would certainly improve, while others would get unexpectedly worse. After explaining the administrative system for dealing with the disabled and outlining the policy adopted with regard to training, he said that the real discouragement lay in the fact that few of the great mass of working men discharged from the army wished to be trained. At the present time disabled men, induced by wages which four years ago would have seemed very high, were to a great extent remaining unskilled if they were unskilled before, or were even passing downwards from the skilled to the unskilled ranks. Contraction of industry would come with the end of the war, and some millions of undischarged and unpensioned soldiers would be wanting work. The weight of industrial depression must fall most heavily on the unskilled men. Lord

Charnwood sketched the chief schemes now in operation, or well advanced in preparation, for supplying this national need, beginning with the cases of the blind and deaf, and dwelling particularly on the limbless cases. The primary work of military orthopaedic hospitals was treatment not training, and a good many men discharged from them would benefit greatly by continuance of orthopaedic treatment as out-patients, while others were sure to relapse, in which event they would benefit by a further stay in hospital. Lord Charnwood asked his hearers to help efforts in their own districts to create orthopaedic annexes to general hospitals and to develop industrial classes at the local technical schools in connexion with the curative processes of the hospitals; the training of men at hospitals for the limbless, for instance, was in most cases only the beginning; it had to be carried further in technical centres or in factories and workshops. A note of caution was sounded with regard to the prospects of small holdings. "Agriculture is not the least skilled of occupations, as some seem to think, but the most skilled. Small-holding requires the right soil, the right neighbourhood, the right small-holder. It requires also some capital. Above all, it is a way of life in which a man stakes much on the continuance of his own full strength till he has strong sons to help him."

Sir Alfred Keogh said that the size and importance of the work of technical training for the disabled would continue to increase, and would become more evident during demobilization. Next to winning the war, nothing could be of more moment than the spread of knowledge on this subject, and it was essential that such knowledge should be diffused early. He spoke of the continued need for voluntary effort by the civil population on behalf of the discharged soldier.

SIR WILLIAM BARTIE.

Surgeon-General Sir William Bartie, V.C., K.C.M.G., who graduated M.B.Glasg. in 1880, was entertained at dinner, during a recent visit of inspection to the north, by the North of England Glasgow University Club, at Newcastle. Dr. J. Chalmers of Sunderland presided, and Sir Thomas Oliver, in proposing the toast of "The guest of the evening and Alma Mater," after paying a tribute to the university, said that a man's success was a result of personal efforts and opportunities offered and accepted, and not of training at any particular university. Surgeon-General Bartie, who had won the V.C. at Colono on December 15th, 1899, had proved himself a worthy son of his Alma Mater. He had only last week returned from visiting the Italian front to superintend the organization of the British medical service there. Sir William Bartie in response, said that in all parts of the world—Gallipoli, Egypt, Salonica, France, and Italy—he had met fellow graduates who had added to the lustre of the university. On behalf of the Army Medical Service he acknowledged the enormous work done by civil medical practitioners. Though successful medical administration was not entirely a matter of professional skill, such skill and knowledge must enter largely into the affairs of military medicine. The best results could only be obtained by a combination of professional skill of a high order with administrative capacity of the first class. The whole gamut of the life of the citizen came within the purview of the medical profession, and he hoped that in future it would take a larger share in public administrative work—in public health, in education, in housing, in dietetics, and in the recreations of the community. The toast of "The Allied Forces" was given by Professor Wright Duff, and acknowledged by Lieut.-Colonel Wells Patterson, and that of "The Chairman" by Lieut.-Colonel Bolam, who elicited a felicitous response from Dr. Chalmers.

Ireland.

MIDWIVES (IRELAND) BILL.

DR. JOSEPH POWER, Vice-Chairman of the Irish Poor Law Medical Committee, Mr. C. H. Gick, Secretary of the Irish Medical Association, and Dr. T. Hennessy, Irish Medical Secretary of the British Medical Association, have had an interview with Sir Henry Robinson, Vice-Chairman, and Dr. E. Coey Bigger, Medical Commissioner of the Local

Government Board (Ireland), in connexion with proposals to amend certain clauses in the Irish Midwives Bill. Dr. Power stated that when the Irish Midwives Bill was being drafted representations were made on behalf of the Poor Law medical officers in Ireland, pointing out that since it was apparently the intention of the promoters of the Irish bill to take as their models the English and Scottish Midwives Acts, it would be necessary that Clause I (2) should be so modified as to prevent untrained women calling in the dispensary doctor on a red ticket to supervise their work in accordance with the Act. The bill as at present drafted permitted untrained women to summon dispensary doctors for the purposes of the Act, and though in such circumstances it was no part of the duties of Poor Law medical officers to attend, yet they were expressly precluded from receiving any remuneration under the bill. Sir Henry Robinson agreed that the objections made by Dr. Power appeared to be well founded, and undertook that Clause I (2) would be amended to remove any disabilities imposed by it in its present form on dispensary doctors.

GRADED SCALES OF SALARIES FOR POOR LAW MEDICAL OFFICERS.

At the last meeting of the Lisburn Board of Guardians a communication signed by all the medical officers in the union was received, requesting the Board to consider their memorial, postponed two years ago, in regard to establishing a graded scale. The memorialists pointed out, in support of their appeal, that the war was prolonged beyond expectation, the cost of living and means of locomotion had increased, the great majority of the unions had fixed graded scales, and some had reviewed them for the second time; that Lisburn was the only union in the north that had not adopted such a scheme. After some discussion notice was given to move the rescission of the former resolution with the view of considering this appeal.

Scotland.

GLASGOW MEDICAL MISSIONARY SOCIETY.

At the fiftieth annual meeting of the Glasgow Medical Missionary Society, in the hall of the Royal Faculty of Physicians and Surgeons, on December 12th, Sir Donald MacAlister, who was in the chair, said that of the founders of the society fifty years ago only one, Dr. J. D. MacLaren, survived. The Rev. Dr. Watson emphasized the importance of housing. The report of the medical superintendent of Moncrief Street Dispensary stated that many of the ailments for which treatment was sought were chronic affections due to or aggravated by the unsatisfactory surroundings in which the people lived. More money was now in the hands of a good many of the working classes and there was less evidence of dire poverty, but children were suffering more than usual, especially among the soldiers' families, on account of the mother going out to work.

PATHOLOGY AT DUNDEE.

At a meeting of the governors of the Dundee Royal Infirmary on December 10th it was announced that as a result of a conference between the directors and the University Court of St. Andrews University in regard to the improvement of the pathological department of the infirmary, plans of a new building scheme would be prepared, but it was not thought possible to undertake any building until peace was restored. In consequence of the good results obtained in the treatment of cancer by the use of radium, a further sum of £300 has been expended in its purchase.

WESTERN INFIRMARY, GLASGOW.

The report of the Western Infirmary, Glasgow, for the year ending October 31st, which was considered at the general meeting on November 29th, showed a large deficit between ordinary income and expenditure. The expenditure was over £56,000 and the income not quite £34,000. The deficit, large as it was, was still larger in the previous year. The extraordinary income from legacies and special donations was over £40,000, and owing to this fortunate circumstance it was possible to meet not only the deficit in ordinary income, but to transfer nearly £17,000 to the stock account. The special appeal for the maintenance

fund had yielded £8,500, leaving, with the sum carried forward from the preceding year, a balance of £15,600. The amount of work done by the infirmary was very large; there were over 9,000 in-patients and nearly 24,000 out-patients, both figures being below those of the previous year. The average daily number of in-patients was 547, compared with 540 last year, but the average period of residence of each was rather longer. Of the indoor patients, 1,945 were medical, 6,219 surgical, and 267 gynaecological. The resident staff numbered 344, the non-resident staff 463. Votes of thanks to the medical and surgical staff were adopted on the motion of Lord Inverclyde, seconded by Colonel Roxburgh.

Correspondence.

WAR EMERGENCY FUND OF THE ROYAL MEDICAL BENEVOLENT FUND.

An Appeal to Members of the British Medical Association.

SIR,—We wish to enlist the secretaries of every Division of the Association in an effort to raise a large subscription to the War Emergency Fund of the Royal Medical Benevolent Fund.

By its first appeal the Fund raised £4,000. The second appeal has raised another £10,000, the subscriptions having been acknowledged from time to time in the medical journals. But there are many who have not yet subscribed, and the Fund is anxious to raise at least £30,000. We believe it is only necessary to bring the appeal effectively before every member of our profession to secure that the money shall be obtained easily and promptly.

The object of the Fund is stated as follows in the words of the latest appeal issued by the Fund:

This Fund was instituted last year to afford assistance to members of our profession who, in consequence of having joined the medical service of the navy or army, find themselves in temporary difficulties.

Many medical men when called up had to leave on very short notice, without time to make adequate provision for the continuance and maintenance of their practices during their absence. As a result they have had to face a severe fall in income even when supplemented by army pay; while many expenses such as rent, insurance, taxes, family maintenance, and education, could not be reduced. Although in a year or two after their return it may be hoped those affected will recover their position, still in the interval help is and will be necessary, and it is to meet these needs that the War Emergency Fund was established.

To be effective the grants must be made on a liberal scale, and the fund from which they are to be drawn must be a large one. The sum obtained last year was about £4,000. This is quite inadequate, as at least £25,000 will be required, if even a small proportion of those requiring assistance is to be helped. From the wealthier members of the medical profession, it is hoped, substantial sums will be received, but every one should feel it a duty which he owes to his less prosperous colleagues to give the most liberal donation he can afford.

There never was a better opportunity for showing the efficiency and utility of the machinery of the Association, and we sincerely trust that every Division will set to work in friendly rivalry to show what it can do in the way of raising money when it has a cause such as this.

Each Division will, of course, use the method it deems most likely to be effective. Some will no doubt canvass the practitioners in their area personally; some will appeal by means of a circular; others will use both methods. But we hope that no stone will be left unturned to make the result worthy of the Association and of the men on whose behalf the appeal is being made.

The contributions should be sent in at intervals to the Financial Secretary and Business Manager, 429, Strand, W.C.2; by the Secretary of the Division; or by any officer specially appointed for the purpose. Cheques should be made payable to the "War Emergency Fund."

They will be acknowledged in the *BRITISH MEDICAL JOURNAL*, and forwarded to the Treasurer of the Fund.—We are, etc.,

CLIFFORD ALLBUTT,

President.

E. B. TURNER,

Chairman of Representative Meetings.

J. A. MACDONALD,

Chairman of Council.

G. E. HASLIP,

Treasurer.

British Medical Association, Dec. 15th, 1917.

THE THEORY OF IMMUNITY.

SIR,—My thanks are due to Mr. Morley Roberts for drawing attention to the simple theory of immune reactions enunciated in the paper by Moore and Whitley in vol. iv of the *Biochemical Journal* (March, 1909, p. 165). Progress in our knowledge of the biochemistry of immunity will be delayed so long as the modes of thought connoted by the series of *ad hoc* terms first introduced by Ehrlich and since reduplicated by others, are allowed to dominate the clear view that the laws of immunity are the laws of reaction by adsorption in colloidal solution. There is nothing new whatever or ever was in the side-chain theory except the fantastic terms. Side-chains were known, and their influence in modifying chemical reactions were known to workers in pure organic chemistry before the birth of Ehrlich. Many experimental attempts to follow up the effects of variations in the side-chain upon pharmacological action of drugs were made before Ehrlich extended his side-chain theory of immunity into therapeutics.

The pioneer work on immunity which has carried us so far forward in many a domain of pathology and bacteriology was that of Bordet, Gengou, and others of the French school; it was burdened from Germany with the intolerable weight of a useless philosophy of jangling terms for a type of reaction well known in colloidal chemistry. Those who wish to study the energetics of these colloidal systems in greater detail will find some assistance in two series of articles published by the writer in 1906 and 1909,¹ and the conditions of adsorption in colloidal solutions, particularly in the latter series.²

The side-chain theory, as the pure organic chemist understands the term, breaks down completely when attempts are made to press it beyond a certain length in elucidation of the activities of living organisms or their products. The reason is obviously that the reactions are no longer between side groups of single organic molecules with true chemical union of constituent atoms of the two reacting molecules, but between colloidal groups of molecules, or two solution-aggregates each of which contains perhaps as many as sixty molecules.

The reacting galaxy is not a molecule any longer, but a band of molecules, and the union is no longer consummated by a rupture across of atomic linkage, but by surface and electrical affinities in which the attractions are between one colloid group and another as a whole, and not by firm union at two particular points.

All the laws of immune reactions can be illustrated by colloidal systems which are not and never were living, and the preservation of a special set of terms is redundant.

The paper quoted by Mr. Morley Roberts illustrates this by showing the similarity between the reactions of enzymes, whether hydrolyzing or oxidizing, and the reactions of immunology, for example, that the colloidal complex, antigen, complement, and immune body, can be compared with substrate, co-enzyme, enzyme.

Other examples might be multiplied, but one which may appeal to the bacteriologist and assist him in grasping the fundamental likeness of all the reactions in this immense field of colloidal reactions is that which he employs daily when he utilizes a multiple stain to differentiate tissues. The triad here is colloidal substrate varying from tissue to tissue, mordant which may or may not be a colloid, and the dye-stuff which is either colloidal at the outset or becomes so during the reaction. The dyes here give an outward and visible sign of what occurs in immunizing reactions, in differential therapeutic action, in anaesthesia,

¹ Moore, in *Recent Advances in Physiology and Biochemistry*, edited by Leonard Hill. London: Arnold, 1906.

² *Further Advances in Physiology*, *ibid.*, 1909, pp. 1-33.

and in a thousand and one reactions of physico-chemical nature occurring in the body. According to the various types of physical or colloidal aggregation in the minute structure of the tissue, this possesses varying affinities for mordant and dye stuff, and so one constituent takes up one dye, and another is marked out by another dye.

The complement, or coferment, or mordant which appears to cement the two reacting colloidal systems, is often the less highly organized and specific in character, and may in some cases be an inorganic salt, or the acidity or alkalinity of the system determined by the state of balance of hydrogen and hydroxyl ions.

The important point to remember and to continue to investigate is the peculiar lability or reactivity conferred upon the colloidal system as its complexity is increased. This gives it the power of taking up external energy forms from the environment; it may be the energy of light, or chemical energy in simpler organic forms, and building this up in a kind of evolution which forms the living cell's life-history.—I am, etc.,

December 10th.

BENJAMIN MOORE.

PRIMARY EXCISION OF GUNSHOT WOUNDS OF THE ELBOW JOINT.

SIR,—In common with your correspondents in the JOURNAL of November 24th, p. 704, I have read Colonel Mansell Moullin's article on this subject with great interest. But I am strongly impressed with the fact that there is another side to the picture which he draws, and that this is unfavourable to the practice that he advocates.

My own experience has been that primary excision of the elbow-joint performed in the presence of virulent sepsis does either too little or too much. Either it does too little, because rapid osteogenesis takes place, resulting in firm ankylosis; or else it does too much, and the patient is left with a flail elbow. I am quite aware that in my present position, in charge of an orthopaedic centre, it is only natural that I should see more of the failures than of the successes of a particular method of treatment, and I do not wish to suggest that primary excision never gives a good result. But as Major Swan points out, septic gunshot wounds cannot be judged by the standard of closed comminuted fractures, and the numerous cases of ankylosis or flail elbow which come under my care make me feel it necessary to utter a word of warning against the routine use of this practice. It seems to me that the utmost conservatism, consistent with thorough drainage and mechanical cleansing of the wound, should be the guiding principle in the primary treatment of this as of other septic wounds. In the elbow-joint this principle will include the removal of fragments of bone already detached from the articular ends; but this is a very different thing indeed from a formal incision involving the wide opening up of fresh tissues, including the shafts of the bones. Very free drainage can be obtained in cases of special severity by cutting across the olecranon process and flexing the elbow. Later on, the olecranon can be reattached to the ulna. But this detachment of the olecranon I would regard as only an exceptional expedient, being content in the majority of cases with the removal of bone fragments and the excision of the infected wounds. Later on, if ankylosis or limitation of movement requires operative treatment, I think that this should consist in removal of the lower end of the humerus, shaping it as a transverse V, and covering it with fatty fascia. The olecranon should always be preserved, if possible, so as to retain the action of the triceps. The head of the radius is cut off only when ankylosis of the superior radio-ulna articulation exists.

In conclusion, I would summarize my view about the excision of this joint, and the same view applies to other articulations, as follows: it is a dangerous principle to advocate the routine excision of the joint as a primary method of treatment, because it is impossible to foresee the result of active sepsis upon a large operation area. Primary treatment should consist in the minimum required for aseptic healing, this minimum including the removal of broken fragments of the articular surfaces. Only at a later date, when sepsis has been eliminated, can an exact correlation be obtained between the injury which has to be treated and the measures which are necessary for its treatment.—I am, etc.,

ERNEST W. HEY GROVES,
Major R.A.M.C.(T) in charge of the
Bristol Orthopaedic Centre.

December 15th.

TRANSFUSION OF WHOLE BLOOD.

SIR,—With regard to the reference you were good enough to make to my letter in the BRITISH MEDICAL JOURNAL of December 8th (p. 770) on the subject of transfusion, I trust I may be permitted to point out that you seem to have missed my main point, which is the importance of transfusion from artery to artery *towards the heart*. This by setting up a good head of pressure in the arterial system at once fills the heart of the recipient through the coronary system, and recovery even after excessive haemorrhage is magical.—I am, etc.,

Edinburgh, Dec. 13th.

EDWARD A. SCHÄFER.

STATE MEDICAL SERVICE.

SIR,—A very few years ago the suggestion of a State service to replace the present system of medical attendance by one which would convert the medical profession into a State Department of salaried officers would have been scouted as the fantastic product of a disordered brain. But the rapid advance, in recent years, towards State communalism in many directions has brought the question well within the bounds of possible politics—in fact, its consideration has now become a matter of supreme importance to all who have the interest and welfare of the medical profession and the health of the community at heart. No medical man can now ignore this question, however much he may favour the present system or oppose further lay interference in the governance of a great scientific profession.

Admitted defects in the present system of medical attendance, dissatisfaction with the working of the Insurance Act, the fear of many men now in the R.A.M.C. that they will have little to come back to at the end of the war, and the proposed establishment of a Ministry of Health have hurried this question to the front. There is no doubt that many members even of the medical profession itself are now in favour of a State medical service. But have these men given full thought to the many and grave dangers and difficulties that such a system will produce? Have they, for instance, inquired into the condition and status of the medical profession in Italy?

I shall not attempt here to put down all my views for and against either the present or the proposed system. But for a State medical service I would suggest that either (a) there must be two grades of doctors—one the State officials working for salaries under the orders of the department, and the other the free doctors working on their own lines for fees from those who are willing to pay for their own medical attendance in addition to their medical tax; or (b) the whole profession must be swept into the State service.

In either case it would be manifestly unjust that the State doctors should be called upon to defray for themselves the high cost of their medical education, when they will have to take orders from the department as to where they are to work, what work they shall do, and what they are to be paid.

If a general medical service is to be organized as a department of the State, then this department must supply and educate its own officers in the same way as the navy does. The department must control its medical schools; it must provide yearly for the number of medical students that will be required to keep up the necessary personnel of the service. Those desiring to enter the medical profession would present themselves for preliminary departmental examinations, where the requisite number of students could be selected and drafted to one or other of the various medical schools.

If the department defrayed the cost of the medical education, and thus created its own officers, it might then have some rational claim to dictate what work and what salary each officer should have. It might also select any officer, showing special promise in any particular line, for departmental aid in pursuing that line of study, so that progress and research might be encouraged.

But only by some such scheme as this could it be anything but outrageous selective tyranny to forcibly absorb, as a State department under official control, one of the great learned professions, whilst other professions and trades are allowed to work out their own destinies.—I am, etc.,

Harrow, Dec. 8th.

A. H. WILLIAMS, M.D.

THE VALUE OF THE SANATORIUM.

SIR.—The concluding paragraph in Dr. W. Gordon's letter will be noted with astonishment by most of your readers. He refers to cases "regarded as cured consumption, in which, *bacilli having never been discovered*, the diagnosis, in my opinion, remained in doubt." (The italics are mine.) Surely Dr. Gordon does not dispute that in numerous cases it is perfectly easy to diagnose phthisis long before the appearance of bacilli in the sputum indicates the breaking down of tissue. Cases are constantly met with in which, sputum being absent, the physical signs and symptoms are such as would not deceive the most inexperienced tuberculosis officer. The delay in making a diagnosis because the bacteriological report is "T.B. negative" is an even more important factor in the non-success of sanatorium treatment than the indifference to "the influence of rainy winds," so culpably shown by those responsible for the sites of sanatoriums.

May I add that it was not Dr. Henry MacCormac, but Dr. George Bodington of Sutton Coldfield, who by his writings first advocated the principles of open-air treatment—a member of a despised race called general practitioners, now rapidly becoming extinct, and regarded by the public as incapable of making a diagnosis of phthisis. The fact that Dr. Bodington was not listened to in no way detracts from the honour due to his memory.—I am, etc.,
H. DOWNES.
Hlinminster, Dec. 17th.

MEDICAL STUDENTS IN AND OUT OF THE RANKS.

SIR—I have much sympathy with your correspondent (p. 812). My son is in a somewhat similar position to his. He passed his "little go" late in 1914, and employed the time before he could enter college in studying preliminary science at the local university. Early in 1915, being then 18½ years old, he enlisted, was sent to Egypt and thence to Salonica, so that we have not seen him for over two years.

If he has to remain in the army until the conclusion of hostilities, and one knows not how long after, five years of study after that will make him a middle-aged man before he is able to begin to earn a living. If the army is able to make exceptions, why not include all who have gone so far as to pass an entrance examination and to register as medical students, as my son did? Of course, if the demand for men will not allow them to do this, we must not grumble, but cheerfully give up all that is required of us.—I am, etc.,
Dec. 15th.

QUI SE SENT MORVEUX QU'IL SE MOUCHE.

SIR.—I am entirely in sympathy with the letter signed "Aux absents les os" which appeared in your issue of December 15th, and my position is somewhat similar. I have a son—my only boy—who, although a medical student, had to join up as soon as he attained the age of 18, and he has been in the ranks ever since. He has not touched a medical book since he became a soldier, and complains now that he is unable to concentrate his mind on any scientific study, the excitement and distraction of camp life being too great, so that should he come out of this terrible war safely he will have to begin his studies all over again.

We fathers can neither afford the time nor the money wasted in this way on our boys, more particularly when it can be proved that their services are not absolutely necessary for the success of the war. Why, if one of the big Government departments were thoroughly combed out of A men the numbers obtained thereby would more than replace all the medical students in the services, and strong pressure should be brought to bear on the Army Council to release all men who were bona fide medical students at the time of their enlistment, provided they resumed their medical studies at once.

The British Medical Association has the interests of the profession in its keeping, and the Central Council has this matter in hand, but time is passing, and they should take this matter up without delay. The speech of the chairman of the General Medical Council recently should convince the Government that, in the interests of this country in the future, it is imperative that the supply of medical men be maintained, and that any delay now is making the position of affairs in the near future all the more grave.—I am, etc.,
December 16th.

MEMCO.

REMUNERATION OF RURAL PRACTITIONERS.

SIR.—I congratulate your correspondent (p. 777) who receives 2s. a head for dispensing under the Insurance Act. I dispense all my own medicines in a sparsely populated area of Northumberland, and all my rural neighbours as well as myself have only received 1s. a head for some considerable time past, and never since the inception of this glorious Act have any of us got more than 1s. 6d. I brought this to the notice of the recent conference during the discussion on rural practice, and apparently such an anomaly had never been heard of. The only explanation we can get from our county Insurance Committee is that we have in the past been paid too much—namely, 1s. 6d.; our drug bills are more than double. We thought the 2s. or 1s. 6d. a head for drugs was part of a contract, but apparently there is under the Insurance Act no such thing.—I am, etc.,

Felton, Northumberland, Dec. 8th.

ROBERT A. WELSH.

As we go to press, a letter addressed to the British Medical Association has been received from the Joint Committee of Insurance Commissioners stating that they have been authorized to make a substantial increase as from January 1st, 1917, in the special payments to rural practitioners in respect of mileage, and to make extra payments for mileage for temporary residents and invalided sailors and soldiers.

Obituary.

ELIZABETH GARRETT ANDERSON, M.D.,

CONSULTING PHYSICIAN, NEW HOSPITAL FOR WOMEN, LONDON.

DR. ELIZABETH GARRETT ANDERSON died at Aldeburgh, Suffolk, on December 17th, at the age of 81. She had been in failing health for some years.

Dr. Garrett Anderson is a unique figure in the medical history of England, inasmuch as any account of her life must necessarily cover the whole period of the initiation, continuation, and successful completion of the agitation for the right of entry of women into the medical profession on equal terms with men in Great Britain and Ireland. Miss Elizabeth Garrett was not the first Englishwoman to obtain a medical degree—Miss Elizabeth Blackwell of Bristol having graduated M.D. in the small university of Geneva, in New York State, in 1849—but she was the first to take a diploma in England. She was the second daughter of Newson Garrett, Esq., of Aldeburgh, Suffolk, and was born in London in 1836. She was educated at home and at a private school. She had no very great interest in medical sciences, but after mature consideration she adopted the profession from a strong conviction of its fitness for women. She began a preparation for her studies by attending for three months as a probationary nurse at Middlesex Hospital, learning what she could from doctors and nurses and reading in her spare moments. She found that the only registrable qualification open to a woman was that of the Society of Apothecaries, which by Act was not only allowed, but was required to examine all persons applying to it after they had gone through the necessary preliminary studies and apprenticeship; all the other examining bodies said they could, and would, refuse to examine her. Having found a corporation that could not refuse to let her try for its diploma she set out to get the necessary preliminary education. The required five years' apprenticeship to a practising medical man was easily managed. She was also able to gain admission to the men's classes at Middlesex Hospital Medical School in some of the preliminary sciences, but she was obliged to arrange for special private tuition in anatomy and physiology from recognized lecturers. This private education was received at St. Andrews University and the Extramural School at Edinburgh. She was then allowed to visit the wards of the Middlesex Hospital with the residents, for whilst the honorary staff were inclined individually to let her attend their clinical classes, collectively they were not. One of the residents also coached her in her clinical reading. At the request of the male students, however, she was required to leave the hospital, but managed to attend for clinical work elsewhere, chiefly at the London Hospital; she passed the final L.S.A. examination in 1865.

In 1866 Miss Garrett became general medical attendant at the St. Mary's Dispensary, which was founded that year to enable poor women and children to obtain medical advice from qualified members of their own sex.

The dispensary was largely attended, and in the course of five years more than 40,000 visits were made to it, 9,000 new patients were admitted, and 250 midwifery cases were attended by midwives attached to it, Miss Garrett being called in when necessary. The work at the dispensary grew in importance, and in 1872 it enlarged its premises and scope by instituting 10 beds, and soon afterwards it grew into the New Hospital for Women at 222, Marylebone Road, with 26 beds. At a later date the hospital moved to 144, Euston Road, where it had 42 beds, and with an acting medical staff composed entirely of qualified women. Miss Garrett worked on the staff for over twenty years.

In 1870 Miss Garrett took the degree of M.D. Paris, being the first woman to graduate at that university. Her achievement caused considerable sensation at the time, and Professor Broca publicly congratulated her on it. In 1870 she was appointed visiting physician to the East London Hospital for Children and Dispensary for Women. In the same year she was elected as a member of the first London School Board for Marylebone by a large majority, but she did not hold either of these posts for long as they interfered with her other work. In 1883, during the Postmaster Generalship of Henry Fawcett, her brother-in-law, who was always a strong supporter of the cause of women doctors, she was appointed a member of the medical staff of the General Post Office. It may be recalled in passing that Henry Fawcett was blind, but was able to hold Cabinet rank chiefly through the devoted and able help which his wife, Miss Garrett's sister, afforded him as a private secretary in his parliamentary career.

Miss Garrett's successful attack on the monopoly of medicine was followed by the adoption of a rule by the Court of the Apothecaries' Hall forbidding students to receive any of their medical education privately. Miss Garrett's success, therefore, made it harder than ever, indeed impossible, for a woman to obtain a qualification to practise medicine from a British examining body.

The Medical Act of 1858 provided that all persons then possessing the degree of M.D. of any foreign or colonial university and already practising in this country at the date of the passing of the Act should be entitled to be registered; but that with this exception no medical practitioners could demand registration unless holding a qualification of one of the British examining boards specified in the schedule attached to the Act. These provisions had for their sole object the protection of the public against incompetent practitioners, but when the British examining boards refused to allow women to take their qualifications their effect was to keep women out of the profession in Great Britain and Ireland. One Englishwoman alone, Miss Elizabeth Blackwell, who had taken an American degree in 1849, and had subsequently come back to England, was able to get her name on the first British register published in 1858. Dr. Garrett's name was the next to appear in 1866. The medical profession seemed then to be closed to the women in England after the Court of the Apothecaries' Hall had adopted the rule forbidding private tuition. But there were more women who wished to follow in Miss Garrett's footsteps, and the agitation was continued by Miss Sophia Jex Blake. The charter of the University of London had been so worded as to exclude the possibility of examining women for medical degrees, and the other universities and the examining bodies in London would have nothing to do with the matter, so she made her first application to the University of Edinburgh (1869). The University Court passed a resolution objecting to legislate for only one lady, and shelving the question of allowing women to be educated in the medical classes. This was looked upon as an invitation to other women to approach it with the same object in view, and several more applied for admission. They were helped by scholarships provided by sympathizers, including Miss Garrett. The General Council of the University went so far as to admit women provisionally to the usual preliminary examination in arts prescribed for medical students entering the university, and to the study of medicine in the university, separate classes for them being formed. The women were all registered as medical students in regular order, and they thought they had won their battle.

They were an unusually able group; four or five of

them gained honours in chemistry and physiology mixed class examinations, and Miss Peechey was first of her year in chemistry and qualified for a Hope scholarship, but the Senate, by a narrow majority, decided that she could have a certificate to say that she had attended the chemistry class of the university, but that she could not have the scholarship, since being a woman she was not a member of the class! Feeling ran so high that some of the men students made riotous attacks on the women, who, however, were more capably defended by other sympathizing men students. In the end, and after four years of struggling, the opposing forces proved to be too much and the women left the city for London, where Mrs. Garrett Anderson (she had married Mr. J. G. S. Anderson, of the Orient Line, in 1871) had by this time come to the conclusion that the real solution of the difficulty of women entering the profession was to be found in Englishwomen seeking abroad what was denied them in their own country. Miss Sophia Jex-Blake opposed this view, and, with the help of some medical men sympathizers, Dr. King Chambers, Dr. Anstie, and Mr. A. T. Norton, and Mrs. Anderson, who still, however, thought the time for creating a school for women had not yet come, the London School of Medicine for Women was founded, its first home being in Henrietta Street, Brunswick Square. Miss Jex-Blake, not then being qualified, acted for the time as unofficial secretary to the school. The staff were naturally all men at first, with the exception of Dr. Garrett Anderson, who took the lectureship in midwifery, and who, with Dr. Elizabeth Blackwell, the only other registered medical woman in England, was on the Council. Dr. Garrett Anderson also was instrumental in getting considerable financial support for the school. In 1877 the practice of the Royal Free Hospital was opened to women students, and some years later women became eligible for some of the resident and acting honorary posts.

Dr. Garrett Anderson became lecturer in medicine in 1876, and held this post until 1898; in 1883 she succeeded Mr. Norton as Dean, and retained the post until 1903. During these years she was actively engaged in private practice in London, in which she attained a very large measure of success.

The fight for right of entry into the profession by women had been dragging on in England whilst Miss Jex-Blake was carrying it on at Edinburgh. In 1862 Miss Garrett had approached the Council of the London University, with a good deal of influential support, suggesting that it should have inserted in a new charter for which it was then applying, a clause expressly extending to women the benefits of its examinations, but the Senate decided by the casting vote of its Chancellor, Lord Granville, not to accede to the proposal. After taking the diploma of L.S.A. and the degree M.D., she continued her agitation with growing support, and in 1874 Convocation expressed the opinion that it was desirable that women should be permitted to take degrees in the University of London. Legislation was necessary to carry this out, and in 1876 the broad issue came before Parliament in Mr. Russell Gurney's bill, which empowered all examining boards to examine women in medicine and to grant them the ordinary degree or diploma. This bill became an Act (1876), and next year London University opened its door to women medical students; the charter embodying this was received in 1878. The Royal College of Physicians in Ireland at once took advantage of Mr. Russell Gurney's Act, and opened its school to women and recognized the London School of Medicine for Women. In 1877 the names of five more English qualified women, amongst them being Miss Jex-Blake, appeared in the *Medical Register*. The next examining bodies to open their qualifications to women were the Irish College of Surgeons (1885), and the Conjoint Board in Scotland (1886). The Scottish universities admitted women to medical degrees in 1892.

In 1875, on the suggestion of the Lord President of the Privy Council, the question came before the General Medical Council, which finally, after three days' discussion, expressed the opinion "that the study and practice of medicine and surgery presented special difficulties for women which could not be safely disregarded; but it was not prepared to say that women ought to be excluded from the profession." Some of those who opposed the opening of the profession to women were inclined to allow them to

sit for a special qualification limited to women only, but Mrs. Garrett Anderson would have none of this. What women wanted was the right to take the same qualifications as men.

It was about this time, too (1876), that the legal advisers of the Royal College of Surgeons in England gave their opinion that the College, by its supplemental charter, could be compelled by legal process to examine women and grant them certificates to practise under its registrable Licence in Midwifery. Some women therefore applied for admission to the examination and were accepted as eligible. However, rather than accept defeat the whole Board of Examiners for the licence resigned; the College became "boycotted by its own examiners," as its women critics put it, and the examination for the Licence in Midwifery was discontinued. It was not until 1909 that the qualifying examination of the Conjoint Board of the Royal Colleges of London was opened to women. The modern universities opened their doors to women students at varying times in the latter part of last century.

The story of the admission of women practitioners to the membership of the British Medical Association runs on very similar lines to that for the right to enter the medical profession. Here again Dr. Garrett Anderson was pioneer in the movement. In the Articles of Association in force in the early seventies there was no clause specifically ruling out the rights of women to membership; it was open to any qualified person with registrable diploma, and Dr. Garrett Anderson was elected by the Metropolitan Branch, being the first woman to become a member. At the annual meeting at Bath in 1878, however, a new clause, stating that "No female shall be eligible for election as a member of the Association," was adopted, after a plebiscite, in which 3,072 voted for and 1,051 against the clause. Dr. Garrett Anderson spoke against the clause, and her personality secured for her a much more favourable reception than did the cause which she so ably advocated. As the years passed on the number of medical women on the register grew from 8 in the Bath days to over 100 in the late eighties and 140 in 1892. Their work was not confined to England, and several of the Branches in the Overseas Dominions found the restriction inconvenient and undesirable; they not only invited qualified women to attend their meetings, but they also began to pass resolutions asking that the Bath prohibition might be expunged from the Articles of Association. Many of the former objectors to the opening of the Association to membership of any qualified person began to change their minds, and after sundry preliminary discussions the question was faced again at the meeting at Nottingham in 1892, when, at an extraordinary general meeting, the late Dr. J. H. Galton moved that Article 4 of the Association be altered by expunging the words, "No female shall be eligible for election as a member of the Association." Mrs. Garrett Anderson seconded the proposal, though she thought the terms of it should be somewhat modified, as she was herself still a member of the Association. This time she was addressing an audience which needed no convincing of the justness of her demands; she had already by her professional and public life done this very thoroughly, and she had the satisfaction of seeing the resolution carried in a meeting of about 300 with only three or four dissentients. A further extraordinary general meeting of the Association was held in August in London to consider and, if thought fit, to confirm the special resolution passed at Nottingham. It did think fit, and the entry of women into the Association was confirmed by a large majority.

Mrs. Anderson's honourable connexion with the Association culminated in her election in 1897 as president of the East Anglian Branch, and she presided very successfully over its work for a year. She was also vice-president of the Section of Medicine of the annual meeting of the British Medical Association in 1900, when it met at Ipswich.

Mrs. Garrett Anderson finally retired to live at Aldeburgh, where her family had long resided, and in 1908 a tribute of confidence and respect was paid to her by her election to be mayor of Aldeburgh. This was the first occasion on which such a position was conferred on a woman in England. She sat for many years on the councils of the North London Collegiate School for Girls and of Bedford College. She was also one of the founders and for long honorary secretary of the Imperial Vaccination

League. Her husband died in 1907. She is survived by two children, a son, Sir Alan Anderson, Controller of the Admiralty, and a daughter, Dr. Louisa Garrett Anderson, C.B.E., who has followed in her mother's footsteps.

Dr. Garrett Anderson wrote a few articles on professional subjects, and also many on the special subject of her cause, in the lay press.

A memorial service will be held at Christ Church, Endell Street (Military Hospital) on Saturday (December 22nd) at 11 a.m.

PROFESSOR GEORGE LAW SINCLAIR, who died recently at Jacksonville, Florida, where he had gone on account of his health, first occupied the chair of anatomy at the Halifax Medical College, and afterwards that of nervous and mental diseases. He was also Dean of the College for a number of years. He was a brilliant lecturer and a successful and beloved teacher, but failing health obliged him to give up active work a few years ago. He was born in Norfolk, Virginia, about sixty-five years ago, a son of a naval officer in the Southern Confederacy. He graduated from Columbia University, New York, in 1872. In 1898 he was appointed inspector of humane institutions in the province of Nova Scotia, Canada, and the following year was elected to the Nova Scotia Medical Board as representative of the provincial government. He was superintendent of the Nova Scotia Hospital for the Insane for many years, and was instrumental in establishing a nurses' training school at that institution, and did much to improve conditions at the hospital and in the gaols and county asylums throughout the province. He was a consistent advocate of the establishment of a provincial institution for the care of the feeble-minded.

DR. RAIMUNDO MENOCAL, a leading surgeon of Cuba who died recently, was born in Havana in 1856. While still very young he took part in political struggles by the side of his uncle Gabriel, father of the present president of the Cuban Republic, and was obliged to seek refuge in Spain. He studied in Madrid, and graduated in 1876. On his return to Cuba he was appointed surgeon to the Hospital of San Felipe y Santiago at Havana. In 1886 he obtained by competition a place on the staff of the Hospital Civil. At the outbreak of the war of independence he had again to leave Cuba, this time migrating to the United States. On his return in 1889 he founded the first school for nurses in Cuba which in time was recognized as a State institution. He became professor of clinical surgery in the University of Havana, an appointment to which he afterwards added the chair of dermatology and syphilis. He was a member of the Superior Sanitary Committee and Secretary of the Board of Health. He was twice dean of the faculty of medicine. He was the author of numerous contributions to the literature of surgery and gynaecology, including a textbook of diseases of the skin and syphilis which has gone through two editions. He was a pioneer of antiseptic and aseptic surgery in Cuba.

DR. ELIZABETH FOLLANSBEE, the first woman who practised medicine in Los Angeles, California, died there recently, aged 78. She graduated at Jefferson Medical College, Philadelphia, in 1877, and was Emeritus professor of paediatrics in the University of California.

Universities and Colleges.

UNIVERSITY OF OXFORD.

The following candidates have been approved at the examinations indicated:

SECOND M.B.—*Materia Medica and Pharmacology*: F. G. Hobson, B.A., H. P. Hodge, B.A., E. G. T. Liddell, W. V. Robinson. *Pathology*: E. H. Clewer, F. G. Hobson, C. F. Krige, W. V. Robinson, E. A. Thomas, E. A. Woods. *Forensic Medicine and Public Health*: C. W. W. Armstrong, W. Gover, R. T. F. D. Roberts, G. K. Stone, H. W. Toms, B. Tordoff, E. A. Woods. *Medicine, Surgery, Midwifery*: C. W. W. Armstrong, F. R. Dutton, W. Gover, R. M. Humphreys, R. T. F. D. Roberts, G. K. Stone.

UNIVERSITY OF LONDON.

MEETING OF THE SENATE.

A MEETING of the Senate was held on November 21st.

Examiners.—Mr. G. Mudge has been appointed internal examiner in general biology for the first examinations for

medical degrees in the session 1917-18 in the place of Major Marett Tims. The following were appointed additional examiners for medical degrees, Part II, for internal and external students in the session 1917-18, at which the number of candidates shall exceed 70:—*Anatomy*: Professor F. W. Jones (London School of Medicine for Women, and Mr. A. Macphail (external). *Pharmacology*: Mr. P. P. Laidlaw (Guy's Hospital Medical School) and Dr. H. J. Campbell (external). *Physiology*: Professor F. A. Bainbridge (St. Bartholomew's Hospital Medical School) and Professor E. H. Starling (external). Dr. J. S. Edkins and Professor D. N. Paton (external) have been appointed to act as examiners in physiology at the M.Sc. examination for internal students in December, 1917.

Lectures.—A course of five lectures on dysentery and allied conditions will be given by Mr. F. W. Twort, superintendent of the Brown Institution, in the theatre of the Royal College of Surgeons, Lincoln's Inn Fields, W.C., on December 17th, 19th, 21st, 28th, and 31st, at 4 p.m.; admission is free without ticket.

Fallen Members.—Memorial services for members of the University who have fallen in the war were held on All Saints' day at the Temple Church, and on All Souls' day at St. Martin's-in-the-Fields. The Service papers at these services included a list of 1,079 members of the University who have fallen in the war, arranged according to the schools of the University of which they were members.

UNIVERSITY OF EDINBURGH.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—G. Balsillie, A. O. I. Brownlee, D. Cook, A. C. C. Craig, Kshibendra Mohan Dey, J. W. C. Fairweather, D. T. P. Gay, J. G. Gilruth, J. T. Godfrey, Elisabeth Harper, J. H. Kerr, J. S. C. Lucas, A. S. McKern, W. G. F. O. Morris, S. D. Nurse, V. E. Purves, E. G. Pyott, A. Robertson, Mary J. D. Rutherford, R. L. Stewart, J. A. Stirling, F. B. Sutherland, E. T. N. Taylor, P. F. V. Walsh, D. M. Young, J. W. van Zyl.

UNIVERSITY OF BRISTOL.

THE *University of Bristol Calendar* for the current academic year contains lists of the officers of the University, members of the University Court, Convocation, and teaching staff, and a directory of graduates and undergraduates, together with the regulations for degrees, diplomas, and scholarships, and information concerning institutions open to students of medicine for hospital practice and clinical instruction.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examinations indicated:

SPECIAL FINAL EXAMINATION.—R. J. Bassett, M. B. Gunn, F. L. H. MacDowel, D. E. Young.

FINAL PROFESSIONAL EXAMINATION.—J. H. Barrett, J. J. Brennan, M. J. Broderick, W. E. Cooke, G. H. M. Crutts, J. A. Cunningham, N. A. Filose, P. J. Filose, L. Finckan, J. J. Hayes, H. Hurst, J. A. Hamilton, E. D. Kinsey, W. J. McElhinney, C. O'Connor, B. F. O'Reilly, G. R. Wilson.

D.P.H. C. A. Paulusz, J. P. J. O'Connor, M.B. Major J. Walker (with honours).

Medical News.

THE Royal Dental Hospital, Leicester Square, has received a Christmas gift of £10 from Her Majesty the Queen.

DRS. F. J. ALLAN (M.O.H. Westminster), H. E. Corbin (M.O.H. Stockport), C. E. Goddard (M.O.H. Wembley), and A. M. N. Pringle (M.O.H. Ipswich), have been elected Fellows of the Royal Sanitary Institute.

THE case *Russell v. Docherty*, in which judgement was given in the Court of Sessions, Edinburgh, on December 11th, appears to have decided that when a miner seeks compensation on account of miner's nystagmus under the Workmen's Compensation Act his action lies against his last employers.

THE first of a three months' course of lectures and demonstrations in hospital administration for the diploma in public health to be given at the South-Eastern Hospital of the Metropolitan Asylums Board, New Cross, S.E., by Dr. F. M. Turner, Medical Superintendent, on Tuesdays and Fridays, will begin on January 4th, 1918. The fee for the course is £3 3s.

THE Reading Pathological Society, one of the oldest medical societies in the United Kingdom, has decided to admit lady practitioners to the privileges of membership. On former occasions, when such a proposal was mooted, there has been an adverse majority, but at a crowded meeting of the society held last week the proposal was carried *unanimously*. This society maintains an admirable medical library as well as a pathological museum, which do much to maintain a high standard of practice in Reading and the neighbourhood.

DR. F. J. WALDO, coroner for the City of London and Southwark, in his annual return to the City Corporation, states that the system of warming his court by means of fuelless gas radiators proved unsatisfactory. It did not maintain the desired temperature and illness attributed to carbon-monoxide was produced. Electric stoves are now used, and have proved satisfactory. He adds that his experience may suggest that some part of the malaise and sickness experienced by persons who sit in courts of law may be due to preventable causes, and that an analysis of the air of the court and an examination of the means of ventilation and of heating may disclose some remediable errors.

AT a meeting of the Section of Laryngology of the Royal Society of Medicine on December 7th, the President, Dr. Brown Kelly, showed a collection of dental cysts and cysts of the floor of the nose. He pointed out that dental cysts which invaded the antrum had been regarded erroneously as "hydrops atri Highmori" or "distension of the maxillary sinus by fluids or mucous cysts," whereas the cysts really arose outside the antrum and only pushed their way in as they grew larger. Dental cysts might also produce a bulging of the floor of the nose and by extending upwards raise the ala. They were to be distinguished from cysts of the floor of the nose, which were retention cysts, and presumably arose from long ducts present in this situation. Mr. Tilley said that, in his experience, cysts of the floor of the nose were always associated with carious teeth, and the fluid inside contained cholesterol crystals. Dr. Kelly said that he was sure the retention cysts were not connected with the teeth. He did not know if cholesterol was present in the fluid.

NEW regulations governing the supply of petrol come into force in France on January 1st. They are designed especially to limit consumption in cars used for pleasure or touring, but also affect those used in the discharge of public duties. Upon receipt of a written application the prefect of the department in which the applicant habitually resides may issue a book of petrol cards good for a month, each entitling the holder to five litres. The number of tickets is determined by the prefect, but the owner of a pleasure or touring car cannot be authorized to obtain more than fifty litres a month. Cards not used in the month of issue are to be cancelled, and the car owner must show that he is not hoarding. A car must not be used without a permit, which must be renewed monthly. A permit will only be issued by the prefect if the applicant shows that he is doing work of advantage to the public; the permit will specify the area within which the car may be used. Usually this will be restricted to the immediate neighbourhood; permits to cover a wider area will be issued only on the authority of the Minister of the Interior. These regulations would no doubt include the case of a car used by a doctor in his practice. The prefect may give special permits for a journey to carry sick or wounded. The Ministers of War, the Navy, Munitions, Agriculture, Public Work, and Transport, will issue permits to persons in those services, but the total amount to be issued to each department of a Ministry will be determined monthly by the Minister. The decree allows, under stringent rules, the supply of small quantities of petrol for lighting. Hackney motor cars may not travel more than six kilometres beyond the commune in which they are owned.

THE Commissioner of the American Red Cross in Europe has appointed a Research Committee to assist scientific work carried out in American base hospitals or army laboratories in France; the chairman of the committee is Captain Walter B. Cannon, the secretary, Captain Kenneth Taylor, and among the members are Majors Joseph A. Blake, G. W. Crile, and Harvey Cushing. A central laboratory has been established under Captain Taylor at the Red Cross Military Hospital, No. 2, at 6, Rue Piccini, Paris, XVI, which will co-operate with the laboratory established there under the Robert Walton Goelt Research Fund. It is hoped that workers from other military hospitals will utilize the laboratory for the completion of researches requiring special facilities, and it is intended also to extend like assistance to scientific workers of the allied armies. A library of current medical journals is also being established. A research society has been founded, which will meet once a month in Paris, and a periodical, entitled, *The Medical Bulletin*, will be issued under the direction of the Bureau of Medical and Surgical Information of the American Red Cross in France. It will contain abstracts of papers read at the monthly meetings of the society, and of articles appearing in French, British, and American journals. The first number of this periodical bears date November, 1917, and contains an introduction by Major Alexander Lambert, chief surgeon of the American Red Cross in France, from

which the above particulars are taken. The remaining seventy pages contain abstracts, the first being an account of the conclusions adopted by the Interallied Surgical Conference held in Paris in March and May last.

AN address by Dr. Dwight Hillis, pastor of the famous Plymouth Church at Brooklyn, after a visit in July and August to the parts of France and Belgium from which the Germans had been expelled, has had wide influence in America, for it contained the evidence of an eye-witness. It has now been reprinted here under the title, *Murder Most Foul*, and a very large number of copies is being distributed by Messrs. W. H. Smith and Son.¹ It is a sign either of grace or fear that the German military authorities now so much resent the application to their nation of the name of Hun, and are punishing prisoners upon whom is found evidence of its use. Dr. Hillis recalls the origin of the phrase, which was applied by the Kaiser himself when addressing German troops embarking for China on July 3rd, 1900. "Make yourselves," he said, "more frightful than the Huns under Attila. See that for a thousand years no enemy mentions the very name of Germany without shuddering." To-day the nations shudder but do not fear. Dr. Hillis quotes the manifesto of the ninety-three professors, to show how the doctrine has penetrated through all ranks in Germany, and says that the men who forge the German military machine and practise the Ten Commandments with the "not" left out, have stamped out of the souls of their soldiers every instinct of pity and sympathy.

IN his introduction to the first part of *Admirals of the British Navy*,² Mr. E. V. Lucas very happily applies Matthew Arnold's famous line, "Others abide our question, thou art free," to the Royal Navy. "for, although it baffles curiosity and ends by eliminating it, it is only to substitute faith." Every German soldier, Dr. Hillis said, received a token large as a silver dollar, bidding him strike his enemy dead—"The day of judgement will not ask you for your reasons." The American soldier, Dr. Hillis added, should have on his token, on the one side "In God we trust," and on the other "And in England's navy." There is a certain generic resemblance in the characters Mr. Francis Dodd has interpreted for us in his twelve portraits of British admirals. Mr. Lucas has felt it, but being at fault to define has described it. "We discern," he writes, "the subtle and penetrating influence of the sea, a mistress who will allow no relaxation of vigilance or toil, so swiftly and dangerously changeable can she be." We can only wish each of them in directing or executing, and all under their command, continuance of the good fortune good work deserves in defending our shores and better luck in freeing our trade routes from the steel sharks of the sea, and from raiding destroyers.

¹ Copies can, we understand, be obtained from the bookstalls and agents of this firm.

Letters, Notes, and Answers.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology, Westrand, London*; telephone, 2531, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Artidulate, Westrand, London*; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Medisecra, Westrand, London*; telephone, 2534, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Referee Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

QUERIES.

DR. W. J. YOUNG (Harston, Cambridge) has recently attended a patient who, in her eighth labour, had twins, a boy weighing 8 lb. and a girl 7½ lb. He asks whether these weights are not very high for twins.

LETTERS, NOTES, ETC.

THE DISCOVERER OF THE CAUSE OF SLEEPING SICKNESS. DR. R. N. MOFFAT writes: Though it would be easy enough for me to do so, I do not propose to reply in detail to Dr. Nabarro's letter in your issue of December 15th, as it does not appear to me that any useful purpose would be served thereby. Enough, and more than enough, has now been written for the guidance of posterity, and, fortunately for myself, the correctness of my statements and the value of my evidence do not stand or fall upon the mere *ipse dixit* of Dr.

Nabarro. Should my slight contribution to this controversy ever attract the attention of the future historian, he will, no doubt, note the important fact that my evidence was, at any rate, not that of one who numbered himself among those to whom honour was due.

PREPARATION OF THE SKIN FOR ANTITETANIC INJECTION.

DR. R. W. MORGAN (M.O. Gillingham V.A.D. Hospital) writes: One is surprised to hear that there have been several cases of abscesses reported following on the injection of antitoxin. I have done a large number, and have only seen one case of abscess, and this was done in France, the injection being made into the tissue of mamma of a powerful man, a situation which is unusual and open to objection. I leave my iodine swab on for five minutes, and I never boil my needle, as it spoils its temper and causes pain on insertion. The needles are kept permanently in rectified spirit and washed out with carbolic acid lotion 1 in 20, and again washed out with sterile water to remove the carbolic just before use. I use Parke, Davis and Co.'s needles, Schimmel's patent, on account of the extreme smallness of their calibre. In this way I have done fifteen men in succession, and, so far, have never had any untoward complications.

A CHEAP LOTION.

DR. ALFRED EDDOWES (London) writes: Now that glycerin ought to be used as sparingly as possible in medical practice, even when obtainable, and while there is difficulty in finding a good calamine powder for the preparation of the calamine lotions so much prescribed for skin affections, it is necessary to look for substitutes. It occurred to me that a thin solution of boiled starch might form a useful vehicle. I had the following lotion prepared: Cyllin 3 ss, mucilaginis amyli 5 ij, aq. ad Oj. Three weeks' experience of its use, both in hospital and private practice, has much surpassed my expectations. There is a wide field of usefulness for it in cases of eczema, etc. The mucilage of starch is simply a 2 per cent. boiled solution of starch. It will be obvious that endless modifications in strength and variety of combination can be made if desired.

DRESSINGS AND APPLIANCES.

MRS. E. H. GIBSON, honorary general manager of the Central Depot of the surgical branch of Queen Mary's Needlework Guild, 2, Cavendish Square, W.1, writes to suggest that medical practitioners concerned with the welfare and comfort of soldiers and sailors suffering from wounds or sickness are unaware of the work that is being done by the Central Depot. One of the aims of this organization is to supply the ordinary dressings, appliances, and comforts required for the troops at home and abroad, and efforts are made to arrange for the supply of any special bandages, splints, and the like that a surgeon may have difficulty in procuring through the ordinary channels.

"LINKS WITH THE PAST."

THE volume, *Links with the Past*, is "a brief chronicle of a notable institution" (the Eagle Insurance Company), written by its organization and publicity manager, who must be highly congratulated on his taste in literary and artistic matters. The frontispiece is a pleasing reproduction of E. M. Ward's picture of "the familiar discourse" between King Charles the Second and Nell Gwyn at 79, Pall Mall, the present site of the head office of the Eagle. It is, perhaps, the smallest coincidence, but at least a suggestion of "coming events casting their shadows before" that one of the items in a silversmith's bill of hers for over a thousand pounds reads "the two eagles weighing 1c9 ounces." The history of the company is traced with interesting fragments of contemporary history interspersed from its foundation on October 23rd, 1807, at Cole's coffee-house to its recent amalgamation with the British Dominions Company. The reproductions from old prints and photographs are most successful, and medical men will be interested in those of Sir James McGrigor, the shrewd Aberdonian, for thirty-six years Director-General of the Army Medical Department; of Dr. W. A. Guy, the medical statistician whose textbook on forensic medicine, edited by Sir David Ferrier, was familiar to past generations of medical students, and of Dr. J. W. Ogle, remembered with affection by so many St. George's men. As the price is not mentioned, this attractive little book is perhaps of the nature of bread cast upon the waters, but it is withal well worth collection and consumption.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 5 0
Each additional line	0 0 8
A whole column	3 10 0
A page	10 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

A STUDY OF FIFTY CASES TREATED BY FLAVINE.

BY

CAPTAIN E. F. BASHFORD, M.D., R.A.M.C.,

CAPTAIN J. N. J. HARTLEY, F.R.C.S.E., R.A.M.C.,

AND

CAPTAIN JOHN T. MORRISON, F.R.C.S., R.A.M.C.,
SURGICAL OBSERVATION HUT, — GENERAL HOSPITAL, B.E.F.*(Report to the Medical Research Committee.)*

SINCE the beginning of June one of our wards has been devoted to an investigation of the clinical results of the application of flavine to war wounds. At the same time an attempt has been made to interpret these results with the help of histological and bacteriological methods. The flavine used has been for the most part "aeriflavine" sent out by the Medical Research Committee, but latterly samples of proflavine from the same source were substituted. The results were substantially the same with both.

TECHNIQUE.

The primary object of the work being to confirm the good results claimed by the earliest workers with flavine, we made a point of adhering as closely as possible to the lines of treatment laid down by them.¹

The skin was carefully cleaned with neutral sodium oleate solution and covered with sterile strips of bandage cloth permeated with sterilized vaseline; the wound was swabbed out with gauze wrung lightly out with flavine, all obvious necrotic tissue cut cleanly away, and every recess then packed with strips of dressing soaked with flavine solution (1:1,000). As far as possible lint was used for the dressing, on the ground that it retains within its mesh a much larger quantity of the fluid it is desired to apply to the wound surface than gauze, but it was found that in small or irregular cavities pieces of gauze are often more convenient. In a few cases, where long tracks or pockets difficult of access had to be dealt with, Carrel's tubes were used for the purpose of a four-hourly instillation of the flavine solution, 10 c.cm. per tube. The flavine solution was used throughout at the original strength of 1:1,000, although we notice that certain workers in France² suggest that after a few days it is advisable to dilute it down to 1:5,000. The last step in the dressing was to apply an impermeable covering. For this purpose one or two thicknesses of the bandage cloth soaked in vaseline, already referred to, were used. Needless to say, careful splinting and removal of foreign bodies was carried out where necessary.

TYPES OF CASES DEALT WITH.

On account of the experimental nature of the treatment, the cases were carefully arranged in a series of gradually increasing severity. The wounds, taken as a whole, were not of great gravity, and this fact should be remembered in estimating the value of the treatment.

Almost all had been treated previously at the front by the Carrel-Dakin method within twenty-four hours of being wounded, and, in the majority of instances, very efficiently.

No wounds involving the cavities of the head, chest, or abdomen were included.

METHOD OF INVESTIGATION.

The patients reached our wards at periods varying from one to six days from the date of reception of the wound, and the flavine treatment was then substituted for that of Carrel-Dakin. It was carried on continuously until either the wound became ready for secondary suture, or until, after three weeks' treatment, it had definitely failed to attain the necessary standard for closure.

In a few cases the treatment was stopped in the patient's interest before the three weeks had elapsed. Every attempt was made to eliminate the possibility of personal bias, and to avoid any conclusion which depended on no more than general impression or individual opinion. Accordingly the points chosen for comparative purposes are all objective; they all depend on definite numerical data, easily ascertained and equally easily verified.

1. The average date on which the temperature reached normal is the first of these points of comparison. For this purpose an evening temperature of 99.2° was regarded as normal.

2. The average date upon which the microbial curve reached the suture standard laid down by Carrel.³

Quite apart from its value as an indication of the possibility of definite closure, this suture standard of Carrel's marks a reasonably definite stage in the bacteriological history of a wound, by reference to which the progress of that wound towards healing may be judged of.

3. The average duration of treatment needed before it was possible to close the wounds.

4. The date of complete healing.

The table of results given refers to a consecutive series of fifty patients with infected wounds.

For comparison a similar table of results obtained by the Carrel-Dakin treatment is given, dealing with as nearly parallel a series of fifty patients as possible. The only material difference is that the Carrel-Dakin series was made up of much more seriously wounded men. It included all the severe cases regarded as unsuitable for the flavine series on account of the experimental nature of that treatment. In spite of this the results obtained are sufficiently striking.

CLINICAL COURSE.

It will perhaps first be well to sketch the clinical history of a wound treated by 1:1,000 flavine. When first seen by us, as a rule two or three days after the man was hit, the surface was still red and raw. In pockets and recesses a little pus might be observed; sloughs were beginning to show grey or yellow; sometimes there would be a more or less offensive odour. As has been pointed out, however, the previous treatment had been good, so that the amount of sloughing tissue was usually slight, and most of the cases were not really heavily infected. The flavine dressing was applied, and twenty-four hours later it was found that the surface was a bright yellow colour, especially where fascial or tendinous structures were exposed. Pus was generally very small in amount, and even where it had been present it usually rapidly diminished in quantity. We often, in fact, experienced some difficulty in getting material for smears for bacteriological examination from the wound surfaces.

The surrounding tissues in most cases remained healthy and free from oedema or infiltration. Any spreading infection that already existed generally subsided quickly. In two cases, however, secondary abscesses developed, and in a third there was spread of infection along tendon sheaths, all of which required incisions.

Once established, the appearance just described, which Mr. Maxwell has cleverly caught in his drawings, at present on exhibition at the Army Collection of War Specimens, remained the characteristic of wounds treated by flavine for from two to three weeks. From then onwards the yellow surface, mainly due to the deposition of a tough layer of plastic lymph, gradually disappeared, being replaced by small granulations of a pale pinkish colour. It was very noticeable that where a heavy growth of organisms was present on the wound surface, this change took place much more rapidly, and in a few cases—not more than four or five—really good small dark-red granulations were seen. Throughout this time ingrowth of epithelium was very slow. In the course of the third week it generally started; but up till that period the wounds remained with sharp edges, having almost a punched-out appearance. This point is also brought out in Mr. Maxwell's drawing, and it was a constant feature.

WOUND FLORA.

Meanwhile a watch had been kept on the flora of the wound surface in order that secondary suture might be resorted to at the earliest possible moment.

In wounds treated by the Carrel-Dakin method it is the cocci—streptococci in our experience—which are usually the last to disappear from an infected wound surface.

In these wounds treated by flavine, strangely enough, this was not so. The commonest type of organism to outlive others on the wound surface was a Gram-negative bacillus. This point has already been confirmed by other workers.⁴

It is not at all certain that such organisms need necessarily contraindicate secondary suture, but such experiments as have been made to investigate this problem are not yet sufficiently advanced to enable us to speak with any confidence. Consequently for the most part the wounds were not closed unless they had reached the "suture standard" laid down by Carrel. In two instances, both cases of fracture, the sutures had to be removed, in one on the third, in the other on the fifth day. The firm healing of sutured wounds was noticeably delayed.

RESULTS.

In the chart we have made an attempt to show graphically the rapidity with which wounds treated by flavine became ready for secondary closure by suture.

CHART 1.—Showing graphically the comparative rapidity with which wounds treated by the Carrel-Dakin method and flavine respectively become ready for secondary closure by suture. The classification as "A" cases means that they came under treatment within twenty-four hours of being wounded.

Along the ordinate line are marked the percentage of the fifty cases up to the "suture standard" on any given day, the days being marked along the abscissa. A case that had been sutured was reckoned as still one of the cases up to suture standard.

For purposes of contrast, the graph traced in a similar way for the Carrel-Dakin series is shown. It will be seen that from the tenth day on till the eighteenth the number of flavine cases bacteriologically clean varies from one-third to one-half of the number of cases similarly clean under the Carrel-Dakin treatment. The same result is brought out in a slightly different way in the table given below.

Table of Average Results.

Total number of cases: Flavine 50; Carrel-Dakin method 50.

	Flavine.		Carrel-Dakin.	
	Percentage of Cases.	No. of Days.	Percentage of Cases.	No. of Days.
Temperature normal ...	86	8.8	94	11.7
Suture standard reached ...	38	15.6	68	12.6
Suture performed ...	34	17	54	14.9
Healed ...	22	26.5	56	28.6
Evacuated unhealed ...	78	24	44	36.8
Secondary haemorrhage ...	4	—	0	—
Secondary amputations ...	2	—	4	—
Mortality ...	0	—	0	—

The temperature reached normal distinctly earlier, as a rule, in the flavine group, but the percentage of failures to reach the normal line while under treatment with flavine was rather greater. Under the influence of flavine only 38 per cent. of the cases attained the standard required for suture.

This is in marked contrast to the 68 per cent. under treatment in the Carrel-Dakin series. The superiority of the latter is still maintained when we consider the number of wounds sutured (54 per cent. as opposed to 34 per cent.) and the percentage of patients evacuated to England healed (56 per cent. as opposed to 22 per cent., or more than two and a half times as many).

We hold that the ideals and standards we must aim at consist in the early healing of wounds, and a correspondingly early restoration of the patient to full functional activity. It is no longer sufficient to say "the patient was evacuated doing well, his wounds being clean and granulating." Judged by the higher standards flavine seems to us to have failed, although in two features, the apparent preservation of the surrounding tissues from infiltration and the tendency to inhibit suppuration, its influence is not to be denied.

COMPLICATIONS.

In 8 per cent. of the cases which we treated an irritation of the skin was noted. Round about the wound there appeared first a redness and oedema, and then an eruption, in its early stages papular but later becoming vesicular in character. Cultivation from the blebs failed to reveal any bacterial influence in this complication, and, indeed, it occurred around one wound which was sterile on culture—one of the earliest test cases to which we applied flavine. In 6 per cent. it was sufficiently severe to necessitate change of treatment. Apart from this inconvenience, skin irritation and its results is always a handicap when the moment comes for secondary suture.

Secondary haemorrhage occurred in 4 per cent. of the cases. It is noteworthy that among the Carrel-Dakin series under treatment at the same time no case of secondary haemorrhage occurred.

HISTOLOGY.

The surfaces to which flavine is applied are stained yellow. This staining is apparent microscopically in fifteen minutes, and is more intense in patches. In the course of twenty-four hours it appears as if the wound were covered with a layer of fibrinous exudate, but later the covering looks more like a slough, and it does actually separate from about fourteen days onwards, leaving a granulating surface underneath. To the naked eye the slough appears as a structureless yellow-stained mass. Microscopical examination shows that it consists for the most part of extravasated blood and fibrin, and it is the amount of blood which determines the greater intensity of the yellow staining in some patches. The slowness with which the wounds become clean bacteriologically, as well as the delay in healing, suggested the necessity for a more careful histological examination of what was proceeding in the tissues. For this purpose portions of tissue were excised from nine of the most successful cases immediately before secondary suture at periods varying from two to twenty-one days after wounding, and from two to nineteen days' treatment with flavine. The tissues were fixed in Zenker's solution, cut in serial sections and stained with haematoxylin and eosin. The histological pictures all depart markedly from those figured elsewhere³ for healthy granulation tissue in wounds, and did not show the reaction of muscle undergoing repair treated by other methods. For the purpose of illustration some sketches have been made of the main features early and late in the treatment. Three days after wounding and after two days' treatment with flavine three or four layers can be recognized. There is usually a homogeneous surface layer without the characteristic structure one looks for in fibrin. It is also curiously free from leucocytes. Beneath it there are numerous muscle fibres which have lost their staining reaction and which are embedded in haemorrhages and in a fibrinous exudate containing many entangled leucocytes. The whole structure is in a state of disorganization. There is practically no formation of new capillaries, and scarcely a single muscle bundle shows any sign of regeneration. Some of the muscle fibres are fragmented by haemorrhage or heavily invaded by leucocytes. The third layer exhibits muscle fibres widely separated by exuded fibrin showing the typical network and containing fewer leucocytes. Older (pre-existing) vessels are encountered with their walls heavily infiltrated with leucocytes, and an undue proportion of them exhibit typical thrombosis. Indeed, the stagnation of the blood

FIG. 1.—Sterile wound at three days, and after two days' treatment with flavine. Homogeneous surface layer; disturbance of the formation of granulation tissues and capillaries; delay in muscle regeneration and removal of the processes of repair to deeper layers of muscle; numerous haemorrhages near the surface, fibrinous exudate in deeper layers; thrombosis of deep vessels. Four successive layers can be recognized. $\times 60$ (? reduced).

FIG. 2.—Wound seven days after being received and after five days' treatment with flavine. Haemorrhages and fibrinous exudations of different age blurring the picture as seen in Fig. 1. Dead muscle fibres on the surface, destruction of new granulation tissue, and transference of whole process of repair to the depths. $\times c. 25$.

FIG. 3.—Wound just before secondary closure by suture, twenty-one days after being received, and after nineteen days' treatment with flavine. Interference with ingrowth of epithelium; granulation tissue is abnormal both in cellularity and vascularity; scar tissue not being properly formed (see Fig. 4). $\times c. 25$.

FIG. 5.—Wound comparable with that of Fig. 4, but treated by the Carrel-Dakin method. No interference with the process of healing either in the skin or the granulation tissue has taken place. Formation of normal scar tissue. $\times c. 25$.

FIG. 4.—Portion of same section as in Fig. 3, under higher magnification, showing extensive damage to the vessels, together with haemorrhages, thromboses, and fibrinous exudates. Portion of tissue at lowest level of Fig. 3. $\times c. 60$.

FIG. 6.—Wound to which flavine (1:25) was applied for six days; exaggeration of all the deleterious effects seen in Figs. 1 to 4. Demonstration of the formation of an eschar and extension of the action of flavine to blood vessels below in which the blood is dead and stained with flavine. $\times c. 25$.

is so pronounced that it is easy to pick out a complete series of vessels showing all the features of slowing of the blood stream, deposition of platelets, leucocytes, and formation of fibrinous thrombosis. In the fourth layer normal muscle is approached, the features of the third layer being all present in less marked degree.

Fig. 1 is from a case which, three days after wounding and after two days' treatment with flavine, showed the least disturbance of the formation of granulation tissue and muscle regeneration of any in the series, possibly because it was sterile from the start. The disturbance is, however, evident enough.

At a later date (seven days after wounding and after five days' treatment) the effects of flavine are more pronounced. Several layers can be recognized, but the whole picture is blurred by the very extensive haemorrhages (Fig. 2) and fibrinous exudations. These haemorrhages are obviously of different ages, the oldest are immediately below the surface layer, which shows the same absence of structure as at an earlier date; but in the case chosen for illustration it has formed in the superficial muscle fibres which are dead and devoid of all staining reaction. Beneath this first layer of haemorrhage granulation tissue and capillaries have been forming—partly amongst muscle fibres—when fresh haemorrhages have put an end to both the processes of granulation tissue formation and muscle regeneration. A third extensive haemorrhage has occurred below this earlier granulation tissue and partially surrounds fresh muscle bundles which are now entering on the processes of repair and are widely separated, partly by the formation of fresh granulation tissue, and partly by a fibrinous exudate corresponding to that seen in the third layer of Fig. 1. Thrombosed vessels are found adjacent to the approximately normal muscle, and haemorrhages can also be detected into the sheaths of small nerves. Thus the whole process of repair has been transferred to the depths, a quarter to almost half an inch from the surface. Sections mounted without previous staining show—notwithstanding the amount of flavine dissolved out during repeated sojourns in alcohol—that the haemorrhages are all deeply stained, as are also the red cells contained in the destroyed capillaries of the earlier attempts at granulation tissue. Apart from the bright yellow staining of the dead blood, the processes differ in no essential feature from the production of an eschar by a destructive agent not liquefying the tissues. The delay in healing is due to the advance of this process to a point which corresponds to the limits of the penetration of flavine through the successive layers of tissue killed by its action. The absence of pus on the surface is explained by the absence of any possibility of leucocytes reaching the surface on account of the destruction and poor formation of capillaries. The fact that the wounds do ultimately clean up, in spite of this, is an interesting commentary on the very great stress that has been laid on the importance of pus in the healing of infected wounds.

The latest stage under flavine treatment is reached when secondary suture is performed. The slough has now, as a rule, separated. A typical example, twenty-one days after wounding and after nineteen days' treatment, is shown in Fig. 3. To the naked eye it is evident that the skin is not growing in as rapidly as is to be expected, and where it has grown in its surface is irregularly raised, as if thickened, the reason not being apparent. On sectioning, it is seen that the growth of the epithelium has been seriously interfered with and diverted from the surface of the wound downwards into the depths, so that healthy new epithelium is only found where it can apply itself either to newly formed scar tissue or older dense connective tissue. Towards the wound surface growth has become abortive; the skin has separated into two layers, between which there is an accumulation of leucocytes and some fluid, this being the explanation of the curious appearance above remarked upon. Many leucocytes have also invaded the epithelium throughout the whole length of growth over the wound. They have also invaded an abortive attempt at the production of a papilla which has become vacuolated. The appearances recall those seen in an infected ulcer of the skin or tongue, or in the epithelium adjoining an epithelioma which has become infected. The downgrowth of epithelium away from the granulations exposed to the action of flavine is interesting because it reproduces in man what has been described for the

epithelium of the rabbit's ear after the injection of Scharlach R. by German authors (B. Fischer) some years ago, but wrongly interpreted as being due to stimulation of epithelial growth. From the figures it is quite obvious that it is the exact opposite—a growth away from the area acted on by flavine, and towards tissue not acted on by it.

The granulation tissue at this stage also calls for some comment. As contrasted with healthy granulations, it is remarkably poor in blood vessels. It is also abnormal in the arrangement and number of its various cellular elements. Leucocytes are far too numerous, and scar tissue is not being formed properly. On examining sections under a higher power extensive damage to the existing vessels is observed. In Fig. 4 the vessels at the very bottom of Fig. 3 are shown. They are 5 mm. from the surface. All show an abnormal cellularity of their walls, which are formed sometimes of three or more layers of flattened cells as if there had been previous abnormal proliferation. Many also show thromboses, and in Fig. 4 two capillaries are shown to be obliterated. There are numerous small haemorrhages in the neighbourhood, and a more extensive one in the pre-existent dense connective tissue to the left of the figure. To the left of the long vessel in the centre of the figure much fibrinous exudate is seen. Thus flavine continues to hinder the later processes of healing and the formation of scar tissue by the same sort of action as it exerts on the earlier stages. For the purpose of contrast Fig. 5 has been prepared from a wound treated by the Carrel-Dakin method, but otherwise comparable with the foregoing. It will be observed that not one of the interferences with the process of healing, either in the granulation tissue or the skin, has taken place; indeed, the whole process is quite as normal as in the healing of a sterile bullet wound.⁵

The foregoing description of wounds treated with flavine applies to cases in which the procedure laid down by Browning for the employment of a solution of 1:1,000 had been strictly adhered to. Browning has stated that the use of 1:500 is not harmful, and we believe that others have suggested 1:250. Fig. 6 is from a wound to which a solution of 1:250 flavine was applied for six days without the application of an impermeable covering, but then stopped in the patient's interest. The figure shows in exaggerated degree all the deleterious actions above described both for granulation tissue and skin. The capillaries running up into the flavine eschar are full of blood deeply stained with flavine, both within the scar and for some distance below, indicating that the blood was brought to stagnation and death. The tissue in the eschar has for the most part lost its power of nuclear staining by haematoxylin, and this loss extends somewhat deeper than the obvious staining with flavine. Some of the vessels immediately under the limits of the ingrowth of skin also contain blood stained with flavine, but elsewhere the blood is normal, so that circulating blood corpuscles do not retain flavine, as, indeed, has been proved by intravenous injection. Careful examination of the walls of capillaries containing blood stained with flavine showed that the endothelium was swollen irregularly, and the nuclei vacuolated in some places.

One other late effect of the action of flavine calls for mention. The extent to which the reaction of repair is removed into the depths and tends to involve muscle ultimately leads to a great over-production of scar tissue. To what extent this is liable to produce an undue amount of contraction cannot as yet be determined, but it is certainly not a desirable feature.

The conclusion to be drawn from the foregoing histological observations is that they explain the clinical course of wounds undergoing treatment by flavine, when taken in conjunction with the fact that abundant growths of micro-organisms can be obtained from portions of deeply stained granulation tissue excised after many days' treatment. A review of all the circumstances lends no support to the claim that "the outstanding property of flavine is its selective toxicity to the organisms; thus powerfully bactericidal solutions do not harm the tissues and protective mechanisms of the body." On the contrary, a solution of 1:1,000, far from being innocuous, produces the very deleterious effects recorded above on the entire process of healing, killing successive layers of the reacting tissue elements, including the essential

vascular mechanism, which latter is also an important protective mechanism. The only favourable feature has been that the patient is apparently protected in some way from the absorption of toxic products. Whether this is due to the disturbance of vascularity or to flavine rendering toxic products non-toxic has not been determined. But the employment of flavine and other dyes as if they supplied royal roads to success must be regarded as retrograde steps. However promising this line of inquiry may be for the future, the introduction of fresh substances will only be justified after some such adequate comparative trial as we have done our best to carry out, holding no brief for any particular form of treatment.

CONCLUSIONS.

In the light of the foregoing facts the following points stand out clearly:

The flavine treatment of wounds is associated with—

1. Small formation of pus.
2. Slow epithelial ingrowth.
3. Delay in all the processes of repair.
4. Lingering of organisms on the wound surface.
5. Some diminution in the local and general reaction to infection.

In conclusion, we wish to acknowledge our great indebtedness to Surgeon-General Sir George Makins, to whose foresight and influence the surgical observation hut owes its existence, and to Sir Arthur Sloggett, Director-General of Medical Services in France, for according the necessary facilities for these investigations, as well as to the British Red Cross Society for provision for them. We have also to acknowledge the willingness with which Colonel H. E. Cree, A.M.S., assented to the necessary arrangements being made for the surgical observation hut attached to the general hospital under his command.

THE TREATMENT OF PARAPLEGIA FROM GUNSHOT OR OTHER INJURIES OF THE SPINAL CORD.

BY

COLONEL A. W. MAYO-ROBSON, A.M.S., C.V.O., C.B.,
D.Sc., F.R.C.S.,

CONSULTING SURGEON TO THE SOUTHERN COMMAND.

NOTHING can be more deplorable than the condition of an otherwise healthy man suffering not only from paralysis of the lower extremities, but also of the sphincters of the bladder and rectum.

At present the condition is considered incurable and the patient is condemned to a life of helplessness and misery. But is it incurable? I trust to be able to show that there may be hope for some of these cases by surgical treatment.

The spinal cord is made up of a series of local nerve centres, together with a large amount of conducting material resembling nerve structure which conveys impressions to and from the brain. If continuity is lost, all voluntary action of the nerve centres below the seat of injury is destroyed.

If we can by operative means remedy paralysis due to nerve destruction by transplanting new nerve tissue or part of the spinal cord of one of the lower animals, as I proved possible some years ago,¹ why should we not be able to obtain return of function in a damaged spinal cord by excising the injured section and transplanting into the gap thus made a portion of the spinal cord of a recently killed rabbit, or perhaps better, of a sheep or calf?

I have for some time believed it to be feasible, and I now deliberately propose that such an operation should be tried in cases otherwise incurable.

With due care in asepsis it should be possible to perform the operation without danger to life; and as the paralysis in any suitable case would be complete, the condition of the patient should not be made worse by the operation,

even if it failed to establish continuity. In a case of simple fracture of the spine it may be done as a primary operation, when it is clearly established that the cord is divided or damaged beyond natural repair. If the cord is simply divided, possibly simple suture is all that may be required.

One of the following cases proves the possibility of successful suture, but in the case of gunshot wound the injury will be septic, and it is necessary that the wound should be healed and all trace of septicity absent before the operation I propose can be safely done.

Some years ago I performed laminectomy in the mid-dorsal region in a boy suffering from tuberculous disease of the spine and paraplegia. He ultimately made a complete recovery, and in due course returned to school, he being able to walk, and ultimately even to run about. Unfortunately the spinal support with which he had been furnished was, after a time, discarded, of course without advice, and in time he developed a well marked hunchback, which his fellow schoolboys considered it good fun to ride on. One day, while giving a boy a ride on his back, he fell and fractured his spine at the seat of weakness. This was immediately followed by paralysis.

I saw him shortly after the accident, and cut down on the cord, which I found torn nearly across from behind forwards, the separation behind being in width about half an inch, a small part of the front of the cord only holding together. On straightening the spine the divided ends came into good apposition, and were fixed with fine catgut sutures. The theca of the cord was then closed by a continuous catgut suture, and the rest of the wound was united. The patient was put up at once in plaster-of-Paris in the straight position. There was very little shock, and recovery from the operation was uninterrupted. The function of the lower part of the cord gradually returned, and ultimately he regained power over the sphincters, and recovered the use of his lower extremities.

This case proves that suture of the severed cord can be successfully performed.

During the past six months it has been my duty as well as my pleasure to visit officially the Duchess of Connaught's Canadian Red Cross Hospital at Clivedon, and through the kindness of Colonel Mewburn I have seen a case there that bears out the ideas I had previously held as to the possibility of transplantation to secure continuity of the divided spinal cord.

Acting on the knowledge that I had successfully transplanted the spinal cord of a rabbit into the human subject, the surgeons in charge of a case of gunshot injury of the spine with wound of the cord and consequent paraplegia have performed a most successful operation. The spinal cord was partly divided and otherwise seriously damaged over a limited area by a bullet which had lodged in the spinal canal. The bullet was removed, and after the wound had become germ-free, the edges of the injured part of the cord were pared and a section of the recently removed spinal cord of a rabbit was transplanted into the partly divided cord of the patient.

I have seen the patient on two occasions since the operation, and at my last visit the paraplegia was gradually passing off; function showed signs of returning in the lower extremities and the sphincters were regaining power—in fact, the case promises to be a brilliant success.

Colonel Mewburn has kindly forwarded me an account of the condition of the patient on November 24th, 1917. Sensation has returned from above the nipple line to 3½ in. below that line. There is a general soreness over the rest of the paralysed parts indicating the beginning of return of sensation in the paralysed parts. There is a marked tendon patella reflex, and both legs have sensation when being tapped. Both limbs give a marked continuous clonus. The patient says that he is conscious when his bowels are moving and when the parts are soiled. Bed-sores are healing, and some have quite healed. All the improvements have dated from the time of operation two months ago.

These cases have encouraged me to write this short paper so that others may give a trial to the method I have advocated and so make an attempt to cure some of the deplorable cases of paraplegia up to the present time considered to be incurable.

I have just seen in one of the hospitals of the Southern Command a case of fracture of the seventh dorsal vertebra from gunshot injury in April of this year. The wound has healed soundly and the patient is in good general health except that he is completely paraplegic, including loss of use in the sphincters of the bladder and rectum. The condition of the bladder has been relieved by tho

* This case will doubtless be reported later with full details by the surgeons in charge.

performance of a suprapubic cystotomy. I have advised operation, and I hope shortly to help my colleague, under whose care the man is, to perform laminectomy to be followed by excision of the damaged area of the cord and transplantation of one or more sections of a rabbit's cord into the gap, in order to try to secure conduction of impressions between the upper and lower segments of the man's spinal cord.

There are, I feel sure, many similar cases of invalided soldiers in various institutions throughout the country who would doubtless be willing to undergo operation even if it gives the barest possibility of success.

An Address

ON THE

NECESSITY FOR EDUCATION IN RADIOLOGY
AND ELECTRO-THERAPEUTICS.

DELIVERED TO THE ELECTRO-THERAPEUTICAL SECTION OF
THE ROYAL SOCIETY OF MEDICINE.

BY

G. HARRISON ORTON, M.A., M.D.,

PRESIDENT, ELECTRO-THERAPEUTIC SECTION, ROYAL SOCIETY OF
MEDICINE; RADIOLOGIST TO ST. MARY'S HOSPITAL.

(Abstract.)

DR. ORTON began by referring to the views expressed by Dr. Thurstan Holland in his presidential address to the Röntgen Society,* and in his letter in the JOURNAL of September 15th, 1917, giving an account of the steps taken by the Surgeon-General of the United States Army to organize military radiographic work; as a result of a conference of leading radiologists a number of schools in charge of experts were established for the teaching of radiographic work, which medical officers intending to do x-ray work were required to attend for three months; the x-ray examination of recruits, especially with reference to chest conditions, was organized, and methods for the localization of foreign bodies were considered.

Dr. Orton said that the organization for military x-ray work had been carried out in this country without consultation with leading radiologists, with possibly one exception, and added that the same remark applied to electro-therapeutics. In March, 1917, the council of the Electro-therapeutic Section of the Royal Society of Medicine appointed a small committee, with Sir James Mackenzie as chairman, to consider the best manner in which to deal with questions concerning the status of medical men holding positions as radiologists and electro-therapeutists, and the steps which should be taken for the promotion and teaching of radiology and electro-therapeutics. After full consideration had been given to the matter at several meetings the following letter was addressed to the Vice-Chancellor of the University of Cambridge on May 26th, 1917:

Dear Sir,

The call for some organization of the members of the medical profession who practise radiology and other branches of electro-therapeutics is urgent, and there is great need that some steps should be taken to establish these subjects on a proper footing both in regard to the public and the profession generally. At present no standard exists; there is no organized teaching of the subjects, and those medical men who have taken up this branch of medicine have had to pick up their knowledge almost entirely by experience—at the expense of their patients. The result of this haphazard state of things is well depicted by Captain Thurstan Holland in his presidential address before the Röntgen Society—the lack of knowledge on the part of those who have been responsible for placing totally untrained men, both lay and medical, in charge of most of the military x-ray departments has led to endless tragedies, while in civil practice much suffering would be saved if competent radiologists were in charge of the departments. In civil general hospitals,

where the x-ray department is properly organized, fully 10 per cent. of all the patients who enter the doors of the hospital find their way to this department, and this in spite of the fact that those in charge are so over-burdened with routine work that there is no time for research or the undertaking of new branches of diagnosis and treatment.

As the outcome of a discussion at the Council Meeting of the Electro-therapeutic Section of the Royal Society of Medicine on March 16th of this year a small committee was formed to consider—

- (i) The best means of raising the status of radiology and electro-therapeutics to their rightful place among the branches of medicine, and to attract the better class of medical men to take up these special subjects.
- (ii) To suggest what steps should be taken to provide teaching in radiology and electro-therapeutics.

At this meeting, after a prolonged discussion, a sub-committee was elected to go into this matter. After considering several schemes the subcommittee suggested that it was not advisable to start any programme of teaching in London until it was known if facilities could be offered for granting a diploma at Cambridge or some other university.

It was decided to approach Cambridge University in the matter, as it was stated by one of the members that funds would be found not only to provide for the necessary expenses, but also to equip, maintain, and eventually to endow a Research Hospital and Chair if these facilities were granted by this University.

It is intended that the scheme shall be started on broad lines, in order that development may not be hampered, the objects being:

- (i) To provide a standard in these subjects.
- (ii) To provide the teaching that will be necessary, together with the facilities for hospital experience.

So far as it has advanced at present the scheme of the Subcommittee provides for:

A. A central organization in London, housed in an institute, where teaching facilities would be available in the scientific part of the curriculum, the practical experience being available in the large hospitals. Later, if necessary, centres could be started in other towns.

B. A post-graduate diploma in one of the older universities where a research hospital would be built. This hospital would be devoted to the scientific investigation of the many physiological, pathological, and physical problems that are waiting to be worked out. This hospital would be available for those who wished to work on various problems, and especially for those who were investigating with a view to the M.D. thesis.

Appended you will find outlines of: A, The London Scheme; B, the Cambridge Scheme:

A. The London Scheme.

A representative board, elected annually, would be responsible for this scheme.

1. The intention is to provide a central institute in London, equipped for general organization, and also for post-graduate teaching, where the necessary appliances would be available for demonstrations, and where all lectures on scientific subjects could be given.

2. Arrangements would be made for teaching in physics, chemistry, pathology, and clinical medicine, and for lectures by specially qualified medical men in those branches of radiology in which they had specialized. Special lectures and demonstrations in allied subjects would also be arranged, and whenever distinguished colleagues from abroad visited this country they would be invited to deliver lectures.

3. In conjunction with the university which grants the diploma, the board would draw up the general lines of teaching, not only for the London school, but for any other schools that might be formed.

4. The board would arrange for students to hold appointments as clinical assistants in the various x-ray and electrical departments that would be available in the London hospitals.

5. The board would arrange centres throughout the country in close touch with the central institute, where it would be possible to arrange for post-graduate teaching.

6. The institute would be the centre for the spread of knowledge of these subjects and of the work done in this country; and, if possible, the existing x-ray journal would be utilized as its official organ.

In the future it is probable that many overseas workers will be attracted to this country, and a strong

* Journal of the Röntgen Society, January, 1917, vol. xiii, No. 50. BRITISH MEDICAL JOURNAL, November 18th, 1916, p. 696. A fuller expression of Dr. Holland's view was contained in an address published in the JOURNAL of March 3rd, 1917, p. 285.

effort should be made to establish an attractive post-graduate school where the subjects could be taught in a manner worthy of their importance. It is especially important to get the scheme started as soon as possible, even in a small way, for when the war is over there will be many medical men who have done the comparatively mechanical war x-ray work who will be attracted to the subject, and who will welcome the idea.

Lay assistance is necessary in x-ray and electro-therapeutic work, and provision will have to be made later for the training of qualified assistants, to whom a certificate would be granted.

The next step would be to approach the General Medical Council on the question of the recognition of radiologists, and the making of it illegal for any other than a qualified member to practise these subjects.

This would at once lead to the raising of the standard and the multiplication of posts of responsibility which would attract the better type of medical man to the new subjects.

B. The Scheme for Cambridge.

Clinical material for adequate teaching facilities is not available in Cambridge, but, on the other hand, there is quite sufficient for research, and the intention would be that, while London, and possibly other large towns, are the teaching centres, Cambridge should be the examining and research centre.

For this purpose it is necessary that there should be some man in charge in Cambridge who would, in conjunction with the duly appointed board, make the necessary arrangements for the examinations and undertake the direction of the research hospital.

In the first instance the duty of the man in charge would be to find out what men were at work and what work was being done in the various hospitals throughout the country, and to enlist the active and sympathetic support of all workers, not only in the central institute in London, but also to obtain their co-operation in the research work. As far as possible he should also be in touch with the work that is being done abroad, especially in Canada and the States.

There is room for endless research in radiology, not only on the physical side, but also on the human, for example, in the investigation of the alimentary tract, and especially in the action of drugs, etc., and it is proposed that a research hospital should be started with twelve or more beds and certain laboratories attached; this should be placed as close to the Addenbrooke Hospital and also to the existing laboratories as can be arranged.

In the first place it would be advisable that this hospital should be started in temporary buildings as it is impossible to foresee on what lines the hospital would develop.

Yours, etc.,

Another meeting was held on June 15th, 1917, when the following encouraging replies to the letter addressed to the Vice-Chancellor of Cambridge University were read:

The Vice-Chancellor wrote (May 28th, 1917):

I brought your letter before the Council of the Senate this morning. The proposals contained in the letter were received favourably and the whole question was referred to a special board for medicine, with the request for an answer to the Council before the end of the term.

Dr. Lawrence Humphrey, secretary of the special board for medicine, wrote (June 7th, 1917):

The special board for medicine considered your letter *re* medical radiology and welcomed the proposal. It was unanimously agreed to approve the general principle, and the board were prepared to recommend that steps be taken to institute a diploma. It was thought advisable that the scientific teaching should, as far as possible, be carried on in Cambridge and that the appointment should be rather a director or reader and not a professor. The board appointed a small committee to consider the details and, if desired, to meet members of your committee to discuss the matter.

The Committee further considered that, in view of the importance of the questions involved, and of the necessity for unanimity of opinion, it would be a proper step to invite the leading radiologists and electro-theraputists to attend a meeting, and the Secretary was authorized to call such a meeting and to invite the co-operation of the deans of the various London schools. Most of the deans have replied approving of the scheme, subject to the consideration of details, and there can be no doubt that in the near

future it should be possible to arrange for post-graduate teaching at several of these schools.

The meeting of radiologists and electro-theraputists was held at the Royal Society of Medicine on July 25th, when, after much lengthy argument and discussion, the following resolution was carried unanimously:

That this meeting of medical men practising as radiologists desire to express their approval of the initial steps taken by the gentlemen who have submitted an outline of a scheme, and to thank them heartily for the work they have done; and further we propose that the gentlemen who have already taken action in the matter should form an executive of a larger committee representative of all the London and provincial schools.

If such a body had been in existence at the beginning of the war it would have been in a position to advise the military authorities as to the general organization of radiology and electro-therapeutics, and, further, to undertake the teaching of men appointed to the various departments on standard methods; unfortunately this was not the case. But is it yet too late? From what I have seen and heard even in the last few weeks I should say decidedly No, but I fear nothing so simple as saying No will help us out of the anomalous position in which we find ourselves; but, as Captain Thurstan Holland has truly said, "The time has come to enter a strong protest against the continuance of methods which allow of such anomalies to exist." I think we are now in a position to enter such a protest. From what has been done there appears no doubt that the Cambridge part of the scheme could soon be in active being, if the necessary financial support can be arranged. It remains for us to see that the London scheme is put upon a sound basis, so that the two may be able to co-operate in practical teaching and research work.

To do this we must endeavour to establish a central institute in London with facilities for post-graduate teaching on a fairly large scale, in order that men who desire to study these subjects may be able to do so under conditions comparable with those already established in other countries.

The task is not easy, and I foresee that there are many obstacles still to be overcome, not the least being the lack of funds. The way, however, has been paved, and if we push on with sufficient energy and determination there is no reason why in the near future our efforts should not be crowned with success.

THE MYCOLOGICAL DETECTION AND DETERMINATION OF CERTAIN CARBOHYDRATES AND OTHER CARBON COMPOUNDS IN PATHOLOGICAL WORK.

BY

ALDO CASTELLANI, M.D., M.R.C.P.,

LIEUT.-COLONEL ROYAL ITALIAN MEDICAL SERVICE (NAVY); MEMBER OF PERMANENT COMMITTEE, INTERNATIONAL SANITARY COMMISSION; AND

FRANK E. TAYLOR, M.D., M.Sc., M.R.C.P., F.R.C.S.,

LECTURER ON BACTERIOLOGY, KING'S COLLEGE, UNIVERSITY OF LONDON; PATHOLOGIST, ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

VARIOUS carbohydrates and other carbon compounds are currently used in the identification of certain bacteria and higher fungi. The reverse process may also be carried out, namely, certain hyphomycetes and bacteria presenting permanent biochemical reactions may be used in the determination of various carbohydrates and other carbon compounds in pathological work.

For many years ordinary German yeast has, as is well known, been used in the detection of glucose, but this is the only substance for which so far such method of detection has been employed in pathological investigations. As a matter of fact, the method is scientifically incorrect, at least when using the German yeast obtainable in London, for judging by the results of the investigation of several specimens collected by us, this yeast ferments with the production of gas, not only glucose, but several other sugars. When, therefore, gas is thus produced it does not mean with certainty that the sugar present is glucose; it might be levulose, or some other. To detect glucose recourse should be made to really specific germs for that sugar—namely, germs which will ferment glucose only.

with production of gas; for instance, *Monilia balcanica* Castellani, *Monilia parabalcanica* Cast. We have not specific germs for each of the other sugars and carbohydrates, but, as there are a number of species of hyphomycetes and bacteria which select certain carbohydrates to the exclusion of others, we have found it possible, by using certain of these hyphomycetes and bacteria and comparing the results, to devise a general method with the object of assisting in the detection and identification of some carbon compounds, especially certain sugars and other carbohydrates.

General Principle of the Method.

The three more important sugars which have to be dealt with in physiological and pathological investigations—namely, glucose, lactose, and maltose—may, as is well known, be distinguished by their relative powers of reducing Fehling's solution, and by the characters of their osazones; but they may also be distinguished, in our experience, by a very simple mycological test, which may be carried out as follows:

Make a 1 per cent. solution in peptone water of the substance, which it is assumed is known to be one of the three sugars, and distribute it into two tubes, (1) and (2). Inoculate No. 1 with *Monilia balcanica* Cast., or *M. parabalcanica* Cast., or *M. krusei* Cast. Inoculate No. 2 with *M. pinoyi* Cast. or *M. tropicalis* Cast. Incubate at 37° C. for forty-eight hours, and then read the results. If both tubes present gas, the sugar must be glucose; if No. 1 presents no gas and No. 2 gas, the sugar must be maltose; if neither of the tubes present gas, the sugar must be lactose.

This is explained by the fact that *M. balcanica* Cast., *M. parabalcanica* Cast., or *M. krusei* Cast., while producing gas in glucose, have no action on maltose or lactose; and *M. pinoyi* Cast., or *M. tropicalis* Cast., while fermenting glucose and maltose, have no action on lactose. Acid fermentation without production of gas is not to be taken into account. We have carried out the experiment also with certain species of the genus *Saccharomyces*—either with live organisms or their extracts (zymases).

Instead of hyphomycetes, certain bacteria may be used. Thus:

Inoculate Tube No. 1 with *B. proteus vulgaris* Hauser (P.I. strain); inoculate Tube No. 2 with *B. diffluens* Cast. If both tubes show presence of gas, the sugar is glucose; if No. 1 shows gas and No. 2 no gas, the sugar is maltose; if both No. 1 and No. 2 show no gas, the sugar is lactose.

This is explained by the fact that *B. proteus vulgaris* Hauser (P.I. strain) does not ferment lactose, while it ferments with production of gas, glucose and maltose; and *B. diffluens* Cast. does not ferment lactose and maltose, but does ferment glucose with production of gas.

Differentiation of Fehling-reducing Substances.

If we have a Fehling-reducing substance we can determine which it is of the six sugars which may be found in pathological urines—namely, glucose, levulose, maltose, galactose, lactose, or pentoses—by the following method:

Make a 1 per cent. solution of the substance in sugar-free peptone-water, and distribute it in four tubes, each containing a Durham's fermentation tube. Label them Tube 1, Tube 2, Tube 3, Tube 4. Inoculate No. 1 with *Monilia balcanica* Cast., or *M. parabalcanica* Cast.; No. 2 with *M. krusei* Cast.; No. 3 with *M. pinoyi* Cast.; No. 4 with *M. metalindinensis* Cast. Incubate the tubes at 35° C. for forty-eight hours and then read the results.

- (1) Tubes 1, 2, 3, 4, gas present: the reducing substance is glucose.
- (2) Tube 1 no gas; tubes 2, 3, 4, gas present: the reducing substance is levulose.
- (3) Tube 1 no gas, tube 2 no gas; tubes 3, 4, gas present: the reducing substance is maltose.
- (4) Tubes 1, 2, 3, no gas; tube 4 gas present: the reducing substance is galactose.
- (5) Tubes 1, 2, 3, 4, no gas: the reducing substance is either lactose, a pentose, or a reducing substance belonging to the group creatin, uric acid, hippuric acid, etc.

The above conclusions are easily explained when the biochemical reactions of the four monilias we have used are kept in mind. *M. balcanica* Cast. produces gas only in glucose; *M. krusei* Cast. in glucose and levulose; *M. pinoyi* Cast. in glucose, levulose, and maltose; and *M. metalindinensis* Cast. in glucose, levulose, maltose, and galactose; while none of them produces gas in lactose or the pentoses or any other Fehling-reducing substance we have experimented with.

The reducing substance in which none of the monilias mentioned has produced gas may be further investigated, as follows: Take two tubes (5 and 6) of the 1 per cent. peptone water solution, and inoculate No. 5 with *B. coli* Escherich, and No. 6 with *B. paratyphosus* B. Schottmüller, taking care to use strains producing a large amount of gas. Incubate for forty-eight hours and read the results. If both tubes contain gas, the reducing substance belongs to the so-called pentoses; if No. 5 contains gas and No. 6 no gas, the reducing substance is lactose. This is explained by the fact that *B. coli* Esch. produces gas both in lactose and the pentoses; while *B. paratyphosus* B. Schott., does not ferment lactose, but ferments with production of gas the so-called pentoses (arabinose, etc.). If both tubes show absence of gas, the substance belongs to the non-fermentable group of reducing substances, including uric acid, creatinin hippuric acid, etc.

The working of the method can be seen at a glance in the accompanying table and key.

Table showing Identification of Certain Fehling-reducing Substances.

<i>M. balcanica</i> Cast.	<i>M. krusei</i> Cast.	<i>M. pinoyi</i> Cast.	<i>M. metalindinensis</i> Cast.	<i>B. paratyphosus</i> B. Schott.	<i>B. coli</i> Esch.	Reducing Substance.
+	+	+	+	+	+	Glucose.
0	+	+	+	+	+	Levulose.
0	0	+	+	+	+	Maltose.
0	0	0	+	+	+	Galactose.
0	0	0	0	+	+	Pentoses.
0	0	0	0	0	+	Lactose.
0	0	0	0	0	0	Non-fermentable reducing substances of the groups creatin, hippuric acid, uric acid, etc.

+ = Production of gas; simple acid fermentation is not taken into account.
0 = No gas.

The reducing substance is made into a 1 per cent. peptone water solution. Selected strains of the various organisms with permanent biochemical reactions and producing a large amount of gas should be used.

Key to the Identification of Certain Fehling-reducing Substances.

Inoculate Tube 1 with *Monilia balcanica* Cast.

0; inoculate Tube 2 with *M. krusei* Cast. + = GLUCOSE.

0; inoculate Tube 3 with *M. pinoyi* Cast. + = LEVULOSE.

0; inoculate Tube 4 with *M. metalindinensis* Cast. + = MALTOSÉ.

0; inoculate Tube 5 with *B. coli* Esch., and Tube 6 with *B. paratyphosus* B. Schott. + = GALACTOSE.

<i>B. coli</i> +, <i>B. paratyph.</i> B -, = PENTOSE.	<i>B. coli</i> +, <i>B. paratyph.</i> B 0, = LACTOSE.	<i>B. coli</i> 0, <i>B. paratyph.</i> B 0, = Non-fermentable reducing substances of the groups creatin, uric acid, hippuric acid, etc.
---	---	--

Presence of More than One Reducing Substance.

If the presence of more than one sugar and other carbohydrates is suspected, this may, to a certain extent, be ascertained, and the various carbohydrates determined by our mycological method. Let us assume that a liquid, after gas fermentation with *M. balcanica* Cast., is still fermentable with production of gas by *M. krusei* Cast.—the conclusion is that in addition to glucose the liquid must have contained levulose; strains of *M. balcanica* Cast. and of *M. krusei* Cast. should be used having approximately the same fermentation power on glucose. If, now, the liquid, after exhaustion, first with *M. balcanica* Cast. and then with *M. krusei* Cast., is fermentable with production

of gas by *M. pinoyi* Cast., the presumption is that the liquid contained three sugars—glucose, levulose, and maltose. The explanation is found in the fact that *M. balcanica* Cast. ferments with production of gas glucose only; *M. krusei* Cast., glucose and levulose; *M. pinoyi* Cast., glucose, levulose, and maltose.

There are, however, in certain circumstances some sources of error, but with these, as well as the precautions for avoiding them, and with the whole subject of the presence of more than one reducing substance, we propose dealing in a future paper.

Application of the Method to the Detection of Certain Non-reducing Substances.

The method, using certain species of fungi and bacteria, may be applied to assisting in the detection of certain other substances—saccharose, inosite, dextrin, etc. To help in the identification of saccharose, for instance, make a 1 per cent. peptone water solution of the substance to be examined, and inoculate two of the tubes of the solution with two germs (bacteria or monilias or saccharomyces) identical in all their biochemical reactions except on saccharose; for instance, inoculate No. 1 with *B. coli* Esch. and No. 2 with *B. pseudocoli* Cast. If after forty-eight hours' incubation at 37° C. No. 1 shows absence of gas, while gas is present in No. 2, the sugar is saccharose. With this subject also we propose dealing more fully in a future paper.

Use of the Method in Urine Analysis.

From a number of experiments we have carried out, adding to samples of urine various sugars and other carbohydrates, and also from a few pathological specimens, we can say that the method can be used in urine analysis for the detection and differentiation of certain sugars and other substances—glucose, levulose, lactose, pentose, etc.—provided that the amount of such substances present is not too minute (not less than 0.1 per cent.). The urine is distributed in sterile tubes containing Durham's fermentation tubes or similar devices and inoculated with the organisms mentioned in the table and key. Two points of considerable importance are (1) the urine must be aseptic; if it cannot be collected aseptically it should be sterilized as soon as possible—after distribution in the tubes—by heating in Koch's steamer for thirty minutes on two or three consecutive days. It should never be autoclaved, as this procedure may alter the characters of the sugars and other carbohydrates present. (2) It is of great advantage to add a third or the same amount of peptone water to the urine before inoculation, otherwise the organisms may grow very scantily, and there may be no production of gas.

A METHOD OF SKIN GRAFTING UNDER SEPTIC CONDITIONS.

BY

PAUL BOUSFIELD, M.R.C.S., L.R.C.P.

RESIDENT SURGEON, AMERICAN WOMEN'S HOSPITAL FOR OFFICERS,
LONDON.

THE difficulty which has arisen in connexion with skin grafting is recognized by most military surgeons. In a considerable number of instances grafts have not grown on account of the generally septic conditions prevalent. Hitherto the first principle of successful skin grafting has been the most rigid asepsis, without using antiseptic solutions on the raw surface of the wound, since efficient antiseptic solutions have proved as fatal to the delicate grafts as the bacteria which they sought to eradicate. As a rule, the only solution used by most surgeons has been normal saline. Another difficulty arises when a patient has multiple wounds and the wound to be grafted cannot therefore be retained in the best position possible, so that the grafts are sometimes pulled out of place in handling the dressings.

By the method here described I have been able to obtain successful grafts upon areas which, though "clean" to the naked eye, were still actually suppurating, dressings which had been left on for twenty-four hours showing a certain amount of pus, and even possessing an offensive odour.

The following is a case which seemed less promising at the beginning than any other I have dealt with:

The patient had been wounded in the arm, the head, the back, and the left thigh. The wound in the arm had necessitated a guillotine amputation in France, which had remained septic; the wound in the thigh had been excised in France, and when I received the patient in England it consisted of an area on the posterior surface extending from two inches above the knee to the natal fold. The outer border reached to about one and a half inches in front of the great trochanter, and the inner border to within about one and a quarter inches of the rectum—an area of approximately seventy-two square inches, in which all the skin, superficial fascia, and fat had been removed and had left the hamstring muscles exposed and still in a septic condition in very nearly their whole length. (On first viewing this leg it seemed doubtful whether it could be saved, especially as the wound was of such an irregular shape that a plastic operation by means of which parallel strips of skin might be brought over portions of the exposed surface was not possible.)

For ten days the wound was dressed on every third day with pure sterilized liquid paraffin containing one drachm of ordinary bipp to the ounce. At the end of this period the wound was quite clean at the edges and had granulated well over the muscles; a skin graft under the following conditions was decided upon in spite of the fact that the dressings were still somewhat offensive.

The edges of the wound and the skin of the buttocks, whence the graft was to be taken, were sterilized with iodine; the surface of the wound itself was sprayed with zoel, which the manufacturers inform me is made by mixing 1 lb. of 78 per cent. electrolytic caustic soda ground to pass through a sieve with ten holes to the linear inch, with 1½ lb. of No. 20 pure salt; to this is added 5½ lb. of granulated borax and the whole well shaken together. Combination of the caustic soda with the borax takes place rapidly, resulting in a mixture (zoel) containing 19½ per cent. sodium chloride, 3 to 4 per cent. of sodium diborate, and 76½ to 77½ per cent. of sodium monoborate. I then raised small portions of the skin of the buttocks with forceps and dissected off portions about a quarter of an inch in diameter and one-sixteenth of an inch thick in the centre. I passed a single stitch through each graft and through the granulation tissue, suturing each graft in careful apposition; in all I planted about thirty-five grafts in this way. Again I sprayed with an atomizer a solution of zoel upon the grafted wound, and then dressed the whole with gauze soaked in sterilized paraffin, so that the dressing should not dry and tear off the grafts or cause bleeding when it was changed.

The paraffin dressing was left on for forty-eight hours without removal, but was moistened from time to time with fresh paraffin in order to prevent it from sticking. At this period the dressing had begun to smell, and the edges of the dressing had become green. I therefore re-dressed the wound, and sprayed it again with a 2 per cent. solution of zoel, afterwards again placing over the surface gauze soaked in paraffin. This procedure I repeated from time to time on the average every twenty-four hours, and at the end of twelve days every graft had not only taken but had spread to more than twice its original area.

I have used this method on other cases, of which that quoted is typical, and the success of the technique I ascribe to three outstanding conditions:

1. The fixing by means of sutures of the grafts, so that, although in an awkward position, they cannot be removed when the wound is dressed.
2. The use of liquid paraffin as a medium for the dressing, which prevents any adhesion, and hence movement of the grafts.
3. The use of an antiseptic spray which is efficient in its germicidal powers, and yet non-irritant and non-poisonous to such delicate tissues as skin grafts; this last is, without doubt, the most important of the three.

A NOTE ON SKIN GRAFTING.

BY

NORMAN H. JOY, M.R.C.S.,

THEALE, BERKS.

THERE appears to be a tendency among surgeons to avoid the operation of skin grafting chiefly because, with the usual methods adopted, no great measure of success is obtained. With proper care and attention to certain details there should be very few, if any, failures. The details to be attended to are:

1. The raw surface must be in a good condition for skin grafting—that is, it must be covered with healthy granulations and as free as possible from discharge. If there is much discharge many pieces of grafted skin are raised and so fail to "take." To prevent this the wound should be dressed with 1 in 1,000 flavine for four to seven days before operation. In the cases I have treated by this method

there has been no discharge whatever between the grafts, although I had regarded them as very unsuitable cases before the application of flavine.

2. The grafts should not be covered with any dressing and should be properly protected. At the suggestion of Dr. Culverwell I have used inverted boxes of various sizes and shapes cut to fit the contour of a limb if necessary. A jeweller's or instrument maker's cardboard box is the most suitable. The edges should be slightly padded, and the box should be amply large, so that there is no risk of the padding touching the wound.

3. The technique I have used is as follows: The surface from which the skin is to be taken is prepared in the usual way. The wound is covered with a simple gauze dressing, and when this is removed care is taken to disturb the surface as little as possible. Two razors are employed, so that one can be dipped into boiling water while the other is being used; thus the freshly cut surface heals without any suppuration. The grafts are cut about the size of a postage stamp, and with practice can be cut to almost any shape. The skin and razor are kept thoroughly wet with normal saline, so that the grafts can be more easily cut and removed from the razor. The graft is conveyed to the wound on the razor, and slipped off it with the help of a blunt probe. The grafts are generally placed about one-eighth of an inch apart, but can be closer together in a very clean wound. The box, sterilized beforehand, is adjusted to the part and fastened down by long strips of rubber plaster; the ends of these are thoroughly bandaged, the bandage being brought up to the box as close as possible on all sides, but not over it. As a further safeguard against any chance of slipping the bandage is always used in the form of a spica whenever possible. It is then pinned to the box with a liberal supply of safety-pins. The box remains quite firm for three or four days, when it can be removed. The grafts are then found to be firmly fixed, and any dressing, such as fomentations or red lotion, can be applied.

Lectures

ON

THE ANATOMICAL AND PHYSIOLOGICAL PRINCIPLES UNDERLYING THE TREATMENT OF INJURIES TO MUSCLES, BONES, AND JOINTS.

GIVEN AT THE ROYAL COLLEGE OF SURGEONS OF ENGLAND,
NOVEMBER-DECEMBER, 1917.

BY

PROFESSOR ARTHUR KEITH, M.D., F.R.S.,
CONSERVATOR OF THE MUSEUM.

IV. THE INTRODUCTION OF TENOTOMY.

THE events which led to the introduction of tenotomy as a measure of surgical routine had nothing to do with Hunter's experiments; they occurred nearly thirty years after he was dead.

The man who can best serve as a guide, as we follow the march of events, is William John Little, the son of parents living in comfortable circumstances in the East End of London. Little was born in 1810, and was therefore a contemporary of Hilton. In his infancy he suffered from a fever which left the extensor muscles of his leg (so he informs us) paralysed. As he grew up his left foot became inverted, the heel raised, and a typical talipes equino-varus developed. At the age of 16 he was apprenticed to a neighbouring apothecary, but two years later, in 1828, his indenture being cancelled, he began the study of medicine at the London Hospital. He entered his studies with the fixed intention of discovering what could be done for the relief of such a condition as he suffered from. He found that club-foot was regarded as lying outside the legitimate scope of surgery, and, in the opinion of his teachers, was properly confided, as his own case had been, to the care of bonesetters and sprain rubbers, who treated the condition with manipulations or instruments, often with a fair degree of success. A man whose chief object in devoting himself to medicine had been the alleviation of a personal infirmity—one with which his senior contemporaries Lord Byron and Sir Walter Scott were

afflicted—was not likely to remain content with the comfortless promise of his time. All through his time of study at the London Hospital he sought every opportunity of making himself acquainted with the actual condition of parts in deformed feet; he had a facile command of the French tongue, and during his studenthood followed medical progress in the literature of Paris as well as in that of London. He became particularly interested in the work of Delpech of Paris, who had proposed and carried out in 1816 section of the tendo Achillis for the cure of club-foot. When he had passed through the curriculum of his own hospital he went to study in the *post-mortem* room at Guy's Hospital, under Thomas Hodgkin, and to study comparative anatomy under Dr. Robert Grant at University College. It was in that year (1834) that he settled to a city practice in Billiter Street, and was appointed lecturer on comparative anatomy and physiology at his own hospital—the London. In 1834, being then 24 years of age, he became a Member of this College, but in that year was his failure to obtain a vacant assistant surgeoncy at his hospital. He therefore resolved, as is not unusual under such circumstances, to become a Licentiate of the College of Physicians, and devote himself to medicine. For that purpose it was necessary for him to spend two years at a university. He chose Berlin, drawn thither by the great fame of Johannes Müller. In 1834 we see this lame and somewhat sensitive Englishman set out for Berlin armed with a letter of introduction to Müller from Grant of University College and supported by the status accorded to him because of his office of lecturer in comparative anatomy. When Little entered Müller's laboratory he found there Schwann, Henle, Remak, and the other young men who, a few years later, were to reveal the cellular constitution of living matter. Little had every opportunity given him in Müller's laboratory of continuing his dissections of deformed feet. The condition revealed by his dissections supported the conclusions he had drawn from his investigations in England—namely, that surgeons were in error in believing club-foot to result from an inherent defect in the growth of the bones of the foot; the cause of the deformity lay in the soft parts—particularly in a disordered action of the muscles. With that conclusion Müller agreed. He also concurred with Little in regarding the condition as one which should be amenable to surgical treatment.

Before leaving England Little had read of a young surgeon at Hanover, Stromeyer by name, who had modified Delpech's operation, and was cutting the tendo Achillis for the rectification of club-foot. Müller agreed with Little that such an operation had a rational basis. Hence we find Little, in the summer of his second year of study in Berlin, and the twenty-sixth year of his age, visiting Stromeyer in Hanover.

Stromeyer was only six years Little's senior. He was born in Hanover in 1804, the son of a surgeon there who had strong leanings towards the art as practised in England. After spending almost a year in England, young Stromeyer commenced practice in his native town in 1828. From the outset of his practice Stromeyer applied himself to the treatment of physical disabilities and deformities. He fitted out a small private hospital, but found the establishment of the kind of practice he desired an uphill task. In 1831 his opportunity came. The son of a local schoolmaster, a boy of 14, was the subject of club-foot—intractable, painful, the despair of his relatives and medical attendants. Stromeyer gave the lad a bed in his hospital, and settled down to give his case eighteen months of unremitting attention and care. As a last resort, he cut the tendo Achillis by a new—a subcutaneous—method; he found that the foot could then be flexed (dorsiflexed) and that the cut ends of the tendon separated for three-quarters of an inch. The gap evidently frightened him somewhat; at least he again extended (plantar flexed) the foot until the ends were in apposition, before he fixed it in a splint. At the end of six days he found on bending the foot that the cut ends of the tendon did not separate, but moved together. He gradually dorsiflexed the foot, thus, as he supposed, stretching the scar in the tendon, so that in eight weeks the heel was brought down to its proper level and all trace of the equinus deformity removed. Stromeyer ascribed his success, not to the eighteen months of unremitting attention he had given to the case, but to the operation he had thus introduced into surgery. Tenotomy, he declared, reduced the

time necessary for the cure of club-foot from months to weeks. It brought hope and healing to a neglected class of beings. One great truth he clearly recognized—one which has still to be insisted on—that the theory of congenitalism which had been so consistently applied to a certain class of deformities was a curse to surgical progress; it was used to cover ignorance, and when applied to club-foot prevented surgeons from inquiring into the nature, origin, and ultimate cure of the condition. Nature, he said, could not cure club-foot; it could only make the condition worse. Heat and rubbing, he found, were useless in mending spastic or contracted muscles. He regarded deformities as primarily due to disordered muscular action. To cut the tendon of a spastic or contracted muscle was, therefore, a rational means of treatment. He was impressed by the discoveries of Charles Bell, and in 1836, when Little came under his care, he published a paper on lateral curvatures of the spine, ascribing them to a disordered action of the muscles of respiration. Section of a tendon, he believed, not only relieved the tension of a muscle, but also, as Hunter had concluded, altered its functional behaviour. He observed that a spastically contracted muscle, when its tendon was cut, passed into a condition of rest. Tenotomy he regarded as a means of giving rest to an inflamed joint. He saw how tenotomy could be profitably applied to many regions of the body; he introduced it as a cure for strabismus. Tenotomy was not only a cure for deformities—it gave the surgeon an opportunity of directly affecting the disordered action of a muscle.

Such was the condition of matters when Little entered the modest orthopaedic hospital at Hanover in the July of 1836. There he had his deformity rectified; numerous opportunities were given of perfecting himself in the technique of the new operation; he returned to Berlin convinced that a new era had dawned for the deformed. He showed himself to Müller and to Müller's colleague, Dieffenbach, the surgeon; they were amazed at the success of the Stromeyerian methods. Dieffenbach put them in practice almost immediately; in the course of a little over a year he had operated on 140 cases of club-foot, preferring to rectify the deformity rapidly at the time of operation to the slow post-operative reposition practised by Stromeyer.

Little read his thesis for the doctorate of Berlin University on the nature and treatment of club foot, and early in 1837 returned to London and at once settled down to treat cases of club-foot. His enthusiasm compelled the attention of his British colleagues; some were interested, others were sceptical, many were actively opposed to the new measures. Although of a retiring, modest nature he proved to be the right man to lead a crusade. In 1838, with the help of relatives and friends, he succeeded in establishing the Orthopaedic Institution—afterwards the Royal Orthopaedic Hospital—the first of our public charities for the relief of the maimed and deformed poor. Into the labours of that institution he threw his full strength. In 1839 he published a treatise on *The Nature of Club-foot and Analogous Distortions*—dedicating the work to Sir Astley Cooper. He gave courses of lectures to students on orthopaedic treatment of deformities; he published the course he gave in 1843-44 under the title of *The Nature and Treatment of the Deformities of the Human Frame*.

There can be no doubt that Little was the pioneer of orthopaedic surgery in England. He regarded subcutaneous tenotomy as a great discovery—a surgical revolution. If in this he was too sanguine he at least focussed attention on the treatment of deformities, and particularly on muscles and tendons. We have evidence that his influence and labour made themselves felt in London and Edinburgh. In 1839 James Paget, then a young man of 25, waiting at St. Bartholomew's Hospital for an appointment on the staff, was moved to investigate the repair and blood supply of tendons. He found that tendons were provided with a double supply, (1) from the arteries of the muscle, (2) from the arteries of their sheath. If a tendon were cut, both these supplies took part in furnishing the "callus" of repair with nourishment. In Edinburgh Syme began to practise the operation of tenotomy. He cut tendons in deformed feet and almost immediately turned patients out of hospital to let Nature complete the cure; we know now that in such cases she performs her part very ill.

On Little's return to England he became a Licentiate of

the College of Physicians, and in 1840 was appointed assistant physician to the London Hospital, but the College could not look upon his surgical endeavours with a favourable eye, and he was a man of 67 before his College made him a Fellow. He also had his gains. It was his interest in orthopaedic surgery which drew him to the study of the disordered action of muscles and led to his recognition and description of spastic paralysis (Little's disease). His belief in the efficacy of tenotomy ultimately waned; he came to think that a stretched muscle recovered better than one which had been tenotomized. We find him in 1876, when he gave an address in Edinburgh, towards the end of his professional life, using expressions which show us that his early enthusiasm for tenotomy had become tempered by an experience of forty years. He then realized that tenotomy might be a curse as well as a benefit. Tenotomy applied as the sole measure for the treatment of deformities might have disastrous results. He came to the final conclusion—the same conclusion H. O. Thomas reached—that it was the continuous care of the surgeon, the nursing and coaxing of the parts day by day, with an infinite expenditure of patience, which gave restoration of shape and function to deformed parts. In 1884 William John Little withdrew from active practice to live at West Malling, Kent, where he died in 1894. Stromeyer's career had come to an end long before; he died in 1878, at the age of 74.

To see the principles which guided the practice of the men who followed in the orthopaedic movement started in England by Little, we shall follow the career of William Adams. When Little returned from Berlin in 1837, Adams, a lad of 17, had just been apprenticed to his father, a surgeon in Finsbury Square, in the city of London. He joined St. Thomas's Hospital as a student, working under Hodgkin and Green, and after four years became a Member of this College in 1842. By that time the orthopaedic movement started by Little was well afoot. At Hodgkin's suggestion Adams became curator of the museum at St. Thomas's Hospital and worked there at pathology, waiting for an appointment on the staff, trying at the same time to build up a practice in the city. In 1851, being then 31 years of age and seeing no hope of an appointment to his own hospital, he sought and obtained a place on the staff of the orthopaedic hospital founded by Little. We can see by the way he then set to work that he knew how scientific surgery should be built up. There was still a doubt as to the exact manner in which repair was effected after a tendon is cut. He carried out a series of experiments on sixteen rabbits, cutting the tendo Achillis and studying each stage in the process of repair. His description of the nucleated blastema need not detain us, nor need we linger over his insistence on the part played by the sheath or peritendineum in supplying the material needed to make good the gap in a cut tendon. If time permitted, it would repay us to review the results of his dissections of deformed feet in which the operation of tenotomy had been carried out at varying periods before death occurred from some accidental cause. In one case of tenotomy of the tendo Achillis, he demonstrated that 2½ in. of new tendinous material had become inserted in the course of repair. In another foot, where the tibialis posticus had been cut within its synovial sheath behind the malleolus, he observed that repair had failed, and at the point of section the tendon had become adherent to the bone. Adams availed himself of every opportunity to look beneath the surface and obtain an accurate knowledge of the condition of the deep parts—bones, joints, ligaments, and muscles—which had to be dealt with in the rectification of deformities. He investigated particularly the condition revealed by the dissection of club-foot, and in 1864 was awarded the Jacksonian prize of this College for his dissections and investigations. When, however, we seek for a deeper knowledge of the cause and prevention of deformities and of the action of nerves and muscles, we shall search Adams's publications in vain. With Stromeyer and Little, he believed that deformities should be slowly reduced after the necessary tenotomies had been performed, and that rectification had to be effected by the application of rigid machines.

In 1871 Adams introduced a subcutaneous operation for the relief of ankylosis of the hip-joint. We see in that operation the application of the subcutaneous method to osteotomy. He there applied to the hip-joint a method which had sprung out of the practice introduced by

Stromeyer. Subcutaneous osteotomy, however, had been practised in Germany long before the date at which Adams applied this method to the hip-joint.

THE LAW OF LIGAMENT.

When we examine the principles and practice of Stromeyer, Little, and Adams, all of them pioneers in orthopaedic surgery, we are struck by the importance they attach to ligaments in the production and treatment of deformity; ligaments seemed to them almost as important as muscles. Even now the essential function of ligaments is misunderstood, and so long as this is the case we cannot hope to effect an object which is quite as important as the rectification of deformities—namely, their prevention. Hunter's teaching as regards the respective functions of muscles and ligaments in the mechanism of the human body is very definite. Muscle is the only tissue of the body which can be applied for the continued support of parts without undergoing elongation. A ligament cannot perform that function because it is composed of living passive tissue which must stretch when it is submitted to continued tension. Nature never uses ligaments either for the purpose of passive support or of active maintenance of parts in position: she uses them only for the purpose of limiting movements when the muscles which guard and surround a joint are forced beyond the compass of their normal reach.

This law can be best illustrated at the shoulder-joint. In paralysis of the shoulder muscles, or when a patient is deeply anaesthetized, the head of the humerus drops away from the glenoid cavity under the weight of the arm; the shoulder-joint can then be moved far beyond its normal limits; the ligaments become then the sole agents which limit movements, and are subject to direct stress. If in the dissecting room we strip the muscles from the shoulder and leave the humerus attached merely by its ligaments, we can see then that in all normal movements they never become taut until the usual limits are exceeded. The real ligaments of the shoulder-joint, as of every other joint in the body, are the active defensive contractile muscles.

Now man's upright position has made him more dependent on the ligamentous function of muscles than any other animal. His shoulders, when he stands up or sits up, have to be steadily supported by muscles—every one of the twenty-four vertebrae of his backbone has to be kept continuously balanced one upon the other; the contents of his abdomen have to be constantly braced by the contraction of the muscles of the abdominal wall and thus prevented from falling down. Ligaments are useless for such purposes; Nature never employs them for such ends. We see the same principle applied in the maintenance of the joints of the lower extremities. We cannot stand without the muscular braces of our hip, knee, and ankle joints coming into continuous action. It is easy to demonstrate that the maintenance of the plantar arch owes nothing to ligaments; that can be demonstrated in the living foot and leg, and also in the dissected parts.

It is quite clear that ligaments are passive parts; their elongation is not a cause but a consequence of the deformity. In short, in all static deformities of the human body the cause has to be sought for, not in ligamentous changes, but in the disordered action of the muscles, and we shall never succeed in preventing or mending static deformities until the truth of this law of the function of ligaments is clearly realized.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PROFLAVINE IN SEPTIC WOUNDS.

THE following short notes of five cases of septic gunshot wounds of limbs treated with proflavine at the Kineton Auxiliary Hospital may prove of interest to others engaged in military surgery:

CASE I.

Pte. P. Gunshot wound of right shoulder on July 12th: large wound on back of shoulder, through deltoid muscle. Exposed bone felt with probe. X rays showed fractured scapula below glenoid cavity running into the joint. Piece of metal present in

upper third of arm. The wound was operated on at the casualty clearing station and Carrel treatment used. On admission here on July 25th the wound was very septic and discharging. There was slight rise of temperature at night. Sinus leading to bare bone of scapula plugged with gauze saturated with proflavine 1 in 1,000 in normal saline; dressing covered with protective tissue. Dressed daily for a week. There was a marked decrease in amount of discharge. The wound became healthy and granulating; temperature normal, and the patient doing well.

CASE II.

Pte. O., aged 22. Gunshot wounds of both legs on April 11th. Perforated left tibia: large lacerated wound of left leg, tibia exposed, piece cut away. May 25th, wound very septic; profuse discharge. Wound drained under A.C.E. and several sequestra removed. Cavity packed with bipp paste. Temperature varying between 101° and 98°. On admission here on June 9th wound still very septic. Ensol irrigations and dressings used, and wound improved to a certain extent, becoming cleaner. Proflavine was tried, irrigations of the solution 1 in 2,000 in normal saline through drainage tubes, and gauze packings through sinus on inner side of tibia; the wounds were then covered with gauze saturated in the solution (1 in 1,000), and covered with protective. Dressed daily for ten days, then small vesicular rash appeared on surrounding skin. Saline dressings only were then applied. Previous oedematous condition of leg greatly improved, sensation and movements of the limb returning on August 10th; sequestra separating. Temperature slightly raised at night, but patient's whole condition improved.

CASE III.

Pte. F., aged 28. Gunshot wound of left leg on April 27th; large wound of inner side of left calf. Aponeurosis of deep muscles exposed. Wound excised in France. On admittance to Farnborough V.A.D. Hospital, temperature 103° at night; oedematous swelling on inner side of left ankle. This was excised and a quantity of pus removed, and gauze saturated with carbolic 1 in 20 passed through from upper to lower wound. These wounds were also syringed daily with carbolic solution.

On July 15th patient was transferred to Kineton Hospital, and an incision was made above ankle sinus leading to an abscess in front of tendo Achillis. Cavity irrigated with proflavine 1 in 2,000 in saline solution, and then packed with gauze saturated in solution 1 in 1,000. After a week's treatment, cavity quite clean and ready to heal. Wound now healed, and man sent to Medical Board.

CASE IV.

Cpl. C. Multiple wounds of scalp, right arm, right thigh, leg and buttock; wounds dirty and bone exposed. Transferred from France June 2nd, 1917; admitted Kineton Hospital (stretcher case) June 7th, 1917; wounds still very dirty and several pieces of shell imbedded in wounds of leg. Tibia exposed middle third of shaft. Ensol dressings applied for four days. Flavine gauze applied to leg wound. After two days' treatment the wound started to heal at the edges and was so clean that no swabbing was required. Flavine gauze with protective used for ten days, after which the wound completely healed with saline gauze on fourteenth day.

CASE V.

Pte. C. Gunshot wound of right thigh on September 15th, 1916; compound fracture of femur, middle third. Admitted Southampton Hospital September 28th, 1916. Was transferred to convalescent camp May 16th, 1917. Healed and went on furlough end of May, 1917. Reported sick on June 6th, 1917, admitted Birmingham University Hospital. Abscess opened and bone scraped on June 8th. Transferred to Kineton Hospital (stretcher case) on June 16th with large open wound 5 in. in length (unstitched) exposing shaft of femur. Discharge copious. Bone very painful to press from 1 in. above knee to neck of femur. Packed with ensol gauze and fomented every four hours. Temperature high from June 28th to July 7th. Flavine packing and gauze with protective applied July 7th. About a week later the sinus commenced to heal, and on August 22nd packing was discontinued.

FRED. V. ELKINGTON, L.R.C.P., L.R.C.S.,
Surgeon to Kineton Auxiliary Hospital.

PROLONGED CATHETERIZATION.

A PATIENT, aged 76, has just died after having catheterized himself regularly for fifty-seven years.

At the age of 19 he was a very keen oarsman at Cambridge, and after great exertion in rowing had an attack of what was probably transverse myelitis. His legs were completely paralysed, and he was utterly unable to pass water. The legs gradually recovered so that he could walk with two sticks. The bladder never recovered, and for fifty-seven years he passed a catheter regularly twice a day. He had repeated attacks of orchitis and cystitis. He told me that the urethra had grown so hard that no lubricant was wanted, and that he never used any disinfectant.

Yattendon, Berks.

F. A. BRODRIBB, M.R.C.S., L.R.C.P.

BULLET IN POSTERIOR MEDIASTINUM.

PRIVATE G. H. H., Australian Imperial Force, was wounded at the landing at Anzac Cove, Gallipoli, April 25th, 1915. A rifle bullet entered between the first and second ribs on the left side. He was sent to the 1st Australian General Hospital, Cairo, Egypt, and rejoined his unit at Gallipoli on June 6th, 1915. The diagnosis given was "Bullet in chest." When discharged from hospital he had no embarrassment of respiration and no cardiac symptoms.

He returned to Egypt after the evacuation of Gallipoli, and subsequently went with his battalion to France. He was again wounded on July 24th, 1916, at the capture of Pozieres, when the index finger of his left hand was partly shot away; the remains were subsequently amputated. After his discharge from hospital he passed into a training battalion in November, 1916, and remained there until admitted to No. 2 Australian Auxiliary Hospital on June 30th, 1917, for "breathlessness and debility."

On admission, an antero-posterior skiagraph showed a bullet apparently lying in the outer wall of the left ventricle. On a screen examination, the bullet moved synchronously with the apex beat. A lateral radiograph showed the bullet lying in the posterior wall of the pericardium. Localization was done by Mackenzie Davidson's method and the bullet found to be 12½ cm. beneath a point on the anterior wall of the chest 2 cm. above the apex beat. The patient being rather a thin subject, this corresponded with the lateral radiograph and made the bullet lie in the posterior mediastinum.

The interest of this case is in the fact that the patient was returned to the Gallipoli front and was able apparently to carry out all the arduous duties which are the lot of a private in an infantry battalion for nearly two years.

The patient's condition on admission to this hospital may be gauged from the medical officer's notes on his medical history sheet, which were as follows:—April 25th, 1915: Bullet in chest. July, 1916: Wounded index finger left hand. July, 1917: Complaints of pains in shoulders, and on exertion of shortness of breath. Nothing abnormal found clinically. The patient subsequently went before a medical board, and was recommended for discharge and return to Australia.

A. T. H. NISBET,
Captain A.A.M.S.

Reports

ON

**MEDICAL AND SURGICAL PRACTICE IN
HOSPITALS AND ASYLUMS.****SHEFFIELD ROYAL HOSPITAL.****STRANGULATED OBTURATOR HERNIA.**

(By GORDON F. STONES, M.B., Ch.B., Captain R.A.M.C.(T.),
Resident Surgical Officer.)

Miss C. T., aged 50 years, was admitted on October 17th, 1917, with a history of pain in the lower part of the abdomen, commencing on October 10th and gradually getting worse. Vomiting commenced on October 11th, and since that date she had vomited seven or eight times during each day. For the last two days the vomit had been "like motions." The bowels had not been opened since October 10th. On several occasions during the last two years she had noticed a "pricking, burning sensation" in the right iliac region, striking down the right thigh. This sensation generally lasted for one or two days and was not accompanied by any signs or symptoms of obstruction. The bowels had always been constipated. She had also suffered from palpitation and shortness of breath for the last three or four years. She had been losing flesh for the last year.

The patient was thin and emaciated, with sunken features and anxious countenance. She referred the pain to the lower part of the abdomen, but did not localize one point of maximum intensity. The abdomen was distended and tympanitic. No definite rigidity could be ascertained. The liver dullness was present, although tympanitic distension of the intestines reduced its area. On rectal examination nothing definite could be felt owing to extreme tenderness on the right side of the pelvis. The radial pulse was

markedly intermittent and the beats were irregular both in force and time; rate 80. The rate at the heart was 160. No murmurs were heard. Temperature 96.6°. The external hernial rings were all free from protrusions. A simple enema was given, but no result was obtained.

Operation was performed three-quarters of an hour after admission. An incision was made through the middle line below the umbilicus. On opening the peritoneal cavity about half a pint of straw-coloured fluid escaped. The small intestine was much distended and plum-coloured. On tracing this towards the ileo-caecal junction it was found to enter the right obturator canal, and the collapsed distal loop to continue on to the ileo-caecal junction. Gentle traction was first tried to reduce the intestine from the hernial sac, but this was unsuccessful. The upper fibres of the thyroid membrane were then torn by the tip of the finger. This, aided by firm pressure on the inner side of the right thigh, effected reduction. It was then found that the free border only of the small intestine was involved in the strangulation, and that the mesentery had not entered the hernial sac (Richter's hernia). The gut recovered under bathings of normal saline, and peristaltic waves were observed to pass along the intestine. The patient's condition was rather critical, and the gut was returned, half a pint of saline being poured into the peritoneal cavity. One pint of saline was given into the axillae during the operation. The anaesthetic consisted of open ether, which the patient took fairly well.

The patient recovered from the operation, but vomiting persisted, and death took place thirteen and a half hours later.

A post-mortem examination revealed a sac about the size of a pigeon's egg, behind the right pectineus muscle, and to the outer side of the adductor longus. The obturator artery and nerve ran on the outer and posterior aspect of the neck of the sac.

I am much indebted to the kindness of Captain J. B. Ferguson Wilson, F.R.C.S., R.A.M.C.(T.), under whose care this case was admitted, for allowing me to operate, and to publish these notes.

Rebueloz.**HOW TO AVOID TUBERCULOSIS.**

POPULAR handbooks on medical subjects, written by doctors, but addressed to the public generally, are not as a rule to be commended. In so far as they deal with treatment they are distinctly objectionable, but if employed for the purpose of aiding prevention of disease such works may be of real service not only to the public but also to the doctor by whose advice preventive measures are undertaken. In the attempt to stay the progress of tuberculosis all classes of persons are concerned, and it is essential to success that every one should become acquainted with the main principles involved.

Within the small compass of a pocket volume on *Tuberculosis*,¹ Dr. CLIVE RIVIERE has endeavoured to compress all the essentials of modern knowledge with respect to the incidence and spread of tuberculosis and to point out the means by which the individual may be protected from infection and from the further progress of the disease. The different periods of life are considered in order and the relative danger, as shown by age death-rates, is fully discussed. The extreme susceptibility of the infant under nine months of age renders it necessary to sterilize all milk, if the child be not breast fed, but after a year, Dr. Riviere advocates the use of mixed raw milk in order that the inevitable introduction of the bovine type of bacillus may take place in a very diluted form. This counsel rests upon the basis that almost everyone becomes infected in youth and that a mild dose of bovine bacilli, while it may induce a moderate degree of lymphatic inflammation for a time, does in fact protect the recipient from the attack of the human form of the organism later in life. The precautions that should be taken to avoid such later attacks are fully enumerated and discussed. Many of these precautions, although most easy to observe, are commonly ignored, and the adoption of wiser methods will doubtless

¹ *Tuberculosis*. By Clive Riviere, M.D., F.R.C.P. (Methuen's Health Series.) London: Methuen and Co., Ltd. 1917. (Fcap. 8vo, pp. 127, 1s. net.)

take a very long time to materialize, but the constant repetition of appeals to common sense may bear fruit in the long run.

Dr. Riviere's little book deserves to be read and re-read by everyone who may be called upon to supervise the home life of tuberculous persons and may safely be placed in the hands of such persons themselves.

A PHYSICO-CHEMICAL VIEW OF LIFE.

WHILE the individual processes of digestion, metabolism, production of heat, secretion, and muscular contraction are admitted to be of a purely physico-chemical nature, the reactions of the organism as a whole are usually regarded as the expression of non-physical agencies, as due to design and a directing force outside the scope of biology. The object of Dr. JACQUES LOEB, in his book *The Organism as a Whole*,² is to show that life as a whole can be stated in physico-chemical terms and that there is not any need to invoke the action of non-physical agencies to explain the origin of life. Pasteur's proof that spontaneous generation did not occur in the solutions used by him does not finally decide that a synthesis of living from dead matter is impossible under any conditions, staggering though the difficulties in imagining this may appear. The essential difference between living and non-living matter is that the living cell synthesizes its own complicated specific material from non-specific simple compounds of the surrounding medium, whereas the crystal adds the molecules present in the supersaturated solution. The author long ago (1899) found that the activating effect of the spermatozoon on the ovum can be obtained by a purely physico-chemical agency—namely, by treating the ovum with hypertonic sea water of a definite osmotic pressure for two hours; further, numerous experiments show that the influence of the spermatozoon in inducing development of the ovum consists in an alteration of the cortical layer of the latter, and that this can be caused by other factors. As artificial parthenogenesis proves that the ovum is the future embryo and animal, it appears that the function of the spermatozoon, apart from its activating effect, is confined to the transmission of Mendelian characters.

The idea that the organism as a whole cannot be explained on a physico-chemical basis depends chiefly on the existence of animal instincts and will; but the author reduces instincts to elementary physico-chemical laws, and the conception of design therefore becomes superfluous. The word "environment," for the use of which John Sterling upbraided Carlyle, may easily assume mysterious import, but Dr. Loeb's consideration of the physical and chemical factors which constitute environment leads him to explain its influence on material grounds. The conception of adaptation to environment is submitted to an ingeniously destructive criticism, and this, like other chapters, is likely to meet with opposition; but whether right or wrong, the author is a most serious worker, and this should be borne in mind by any reader who may regard him as a ruthless iconoclast.

IMMORTALITY.

Immortality,³ described as "an essay in discovery co-ordinating scientific, psychical, and biblical research," is an opportune book, not only for the reason suggested in the preface—the loss of so many young lives—but because a stage of scientific investigation has been reached where the very success of such researches as those of Loeb, which appear to account for certain phenomena of fundamental importance in reproduction and development, rather tends to strengthen the opinion that eventually, at some horizon, the physical explanation will fail. The acceptance, indeed, of the doctrine of evolution seems to many to entail the acceptance also of some purposeful intelligence directing the whole process, as Tennyson sang long ago. We believe we are justified in saying that physiologists and practical physicians are as sick as the friends in council who wrote this book can be of "the old bickerings between science and religion, reason and revelation."

² *The Organism as a Whole*. From a Physico-chemical Viewpoint. By Jacques Loeb, M.D., Ph.D., Sc.D., Member of the Rockefeller Institute for Medical Research. New York and London: G. P. Putnam's Sons 1916 (Demy 8vo, pp. x + 379; 51 figures. 12s. 6d. net.)

³ *Immortality*. An Essay in Discovery co-ordinating Scientific, Psychical, and Biblical Research. By Burnett H. Streeter, A. Clutton-Brock, C. W. Pinmet, and J. A. Hadfield. London: Macmillan and Co., Limited. (Medium 8vo, pp. 394. 10s. 6d. net.)

To the majority of physiologists and biologists the two studies are separate, and only related in this respect—that while science is concerned with phenomena and their immediate causes, religion, which seeks the embracing generalization, must concern itself with science as the study which reveals the processes of the universe, and may therefore suggest some answer to the question of what it all means. This is to some considerable extent the point of view taken by Dr. J. A. Hadfield in the chapter he has written on the mind and the brain; it is an able statement, and has the merit of dealing in a short space with a subject very apt to cause prolixity, though some of the clinical details are related at a length which puts the whole out of balance. It has the merit also of avoiding the common fault of accusing medicine of neglecting the influence of the mind on the body; medicine has moved along the same line as biology generally; many things which were mysteries have been shown to be due to physical causes, but this, while limiting the range of conditions attributed to interaction of mind and body, has thrown into the greater prominence the occasions on which this interaction can be verified. Between this, however, and the hypothesis that the mind survives the destruction of the body there is a great gulf. In no capacious spirit we would ask for the definition of the word "nature" as used in the passage quoted below, and of the word "god" as used by Mr. Clutton-Brock in the first chapter of the book—on presuppositions and pre-judgements. It would be well to put the two definitions side by side and see where we were. We could wish, also, that the terms "mind" and "soul" had been defined. Dr. Hadfield uses them as interchangeable (pp. 72, 73), and though he has good authority for this we suspect that both words are needed. Dr. Hadfield seeks to show not only that the doctrine that the mind survives the body is credible and not contradictory to the teaching of science at the present day, but "that science points to this supremacy and liberation of the mind as the goal towards which nature is working." The first proposition seems to be included in any precise definition of science, but the second, so far as it applies to "liberation," seems to rest, in the author's argument, mainly on the acceptance of the facts of telepathy and the explanation of them usually offered. Modern theories of the constitution of the atom, to which Dr. Hadfield makes reference, do not seem really to help. They may be held to strengthen the hypothesis which many philosophers have entertained that matter is a product of energy. It is, indeed, almost impossible to conceive the converse, although not easy to think of the two apart. Even if we make the assumptions that energy is indestructible and that mind is a form of energy, we get no nearer proof of the survival of the individual mind after the death of the body. We have dealt chiefly with a part only of the book in response to what we understood to be an invitation, but the whole may be read with profit, and in particular two chapters by Miss Lily Dougall, the one an acute discussion of "the good and evil in spiritualism," where we again find telepathy a crucial matter, and the other on reincarnation. Speaking generally, the book deals in a spirit of sanity and fairness with problems from the discussion of which these qualities are too often absent.

A SEVENTEENTH-CENTURY FRIENDSHIP.

A CHANCE of the war placed Dr. ARCHIBALD MALLOCH in charge of a small hospital for officers at Burley-on-the-Hill, Rutland, a house rich in historical associations and papers bearing on the lives of two Fellows of the Royal College of Physicians, original Fellows of the Royal Society, and knights—*Finch and Baines*.⁴ Meeting first as pupils of Henry More, the Platonist at Christ's College, Cambridge, where these subsequent benefactors were eventually buried, they enjoyed a veritable David and Jonathan life for thirty-six years, mainly abroad. In 1659 Finch was appointed professor of anatomy at Pisa, being the first, and possibly the only, Englishman to receive the honour; there he investigated the torped fish. From 1672 to 1681 he was ambassador at Constantinople, and when Baines died there he brought back the body to

⁴ *Finch and Baines: A Seventeenth Century Friendship*. By Archibald Malloch, B.A., M.D., temporary Captain C.A.M.C. Cambridge University Press. 1917. (Demy 4to, pp. x + 90; 10 illustrations. 10s. 6d. net.)

Cambridge, and followed his friend to the tomb a year later. Finch, a member of a noble family, though the more prominent in the public eye, was probably indebted for much of his diplomatic and scientific success to his quiet helpmate, who was handicapped for years by poor health and paralysis agitans, and eventually died from the effects of vesical calculus. The interesting story of their varied lives is pleasantly told by Dr. Malloch in scholarly English, and is well illustrated by portraits.

NOTES ON BOOKS.

DR. SOLLMANN'S *Manual of Pharmacology*⁴ is a large volume containing a great deal of information. It is designed to serve the student and the practitioner of medicine both as textbook and a book of reference in pharmacology, and has been brought well up to date. An extensive bibliography is provided, and will be useful to the few who care to trace their information to its source. A sensible and practical feature of the work is that the many unimportant drugs rarely used and without very specific actions are dismissed briefly, while the few important drugs are treated at full length. The text is not divided up into chapters, and so Dr. Sollmann avoids the difficult problem of classifying his drugs according to their actions. The book begins with a general account of the principles and methods of pharmacology, and then plunges into the consideration of the vegetable drugs generally, drugs derived from benzene and synthetic drugs generally, narcotics, hypnotics, serums and vaccines, and the inorganic materia medica. Intercalated are many excellent summaries of the actions of groups of drugs. Skillful use is made of type of various sizes, with the result that both the readers who want to know little and those who want to learn much on any particular point can readily satisfy themselves. The book is primarily meant for use in America, but doses are given in both the metric and the British units, and free use has been made of the British and as well as the United States pharmacopoeia.

Walt Whitman died in 1892 at Camden, N.J., and an appreciation of the man in the last rather pathetic years of his vigorous life is given in a volume entitled *Visits to Walt Whitman*,⁵ by two representatives of a kind of informal private club in Bolton, Lancashire, which met weekly for the discussion of literary and other subjects, and thus got to admire and eventually into correspondence with Whitman. One of this group, Dr. J. JOHNSTON, visited Whitman in 1890, and his published account has long been out of print. It is now reproduced with appreciations by Mr. J. W. WALLACE, and other additions. These contributions contain almost Boswellian records of Whitman's conversations set in an atmosphere of sincere devotion to the author of *Leaves of Grass*, whose magnetism, human personality, and democratic qualities are graphically described. Though Whitman did not say very much about the subject in his books, he expressed himself in conversation as an enthusiastic admirer of the work done by the surgeons in the war between the North and South, and intended when opportunity offered to draw attention in his works to their devotion. Among Whitman's friends Dr. R. M. Bucke, the medical superintendent of an asylum for the insane in Canada, is an interesting and picturesque figure; he was the first in Canada to abandon the old system of restraint, padded rooms and strait-jackets, for a more humane system, and his methods are said to have had considerable influence on the practice of other leading alienists in America. This well illustrated volume will be welcome to students of Walt Whitman, and may interest many who know little about him except his name.

Dr. A. WINKELRIED WILLIAMS, Lecturer on Military Hygiene, Royal Pavilion Military Hospital, Brighton, has published in a small pamphlet the substance of a lecture on *Veneral Diseases and their Prevention*,⁶ which he has given to soldiers at various times and places since the war began. He deals first with the physiology of self-control, next with the preventable causes of sexual irritability, and lastly with the nature, symptoms, and consequences of syphilis and gonorrhoea, with a short note on soft chancre and other infections which may be contracted

during sexual intercourse. Dr. Williams has notes on preventive methods that can be taken by those who risk infection, but of syphilis says that there is no certain method of preventing infection during coitus with a syphilitic person. The pamphlet will be helpful to medical men who may be asked to give a lecture on the subject.

The Transactions of the Ophthalmological Society of the United Kingdom,⁸ vol. xxxvii, contains the communications brought before it during the session 1916-17. It includes Sir George A. Berry's Bowman lecture on colour sense phenomena, and reports of two discussions, the one on a technical subject, "concussion injuries of the visual apparatus," introduced by Mr. A. W. Ormond and Dr. Kinier Wilson, and the other of more general appeal, on the employment of the blind, introduced by Sir A. Pearson. The bulk of the volume is made up mainly of reports of cases, but there is also an interesting contribution by Colonel R. H. Elliot, on the history of couching for cataract. The volume throughout is well illustrated.

Last February we published (p. 252) an abstract of three lectures delivered at the London Hospital by Dr. O. Leyton on the modern treatment of diabetes mellitus. The lectures were published in full in the *Clinical Journal*, and have now been collected in a volume.⁹ They expound the treatment by alimentary rest, sometimes known as the "Allen" treatment, and give full instructions for carrying it out.

⁸ *Transactions of the Ophthalmological Society of the United Kingdom*. Vol. xxxvii. Session 1917. London: J. and A. Churchill. (Demy 8vo, pp. xlv + 394. 12s. 6d. net.)

⁹ *Three Lectures on the Treatment of Diabetes Mellitus by Alimentary Rest (The "Allen" Treatment)*. By O. Leyton, M.D., D.Sc., F.R.C.P. London: Aliard and Son and West Newman, Limited, 1917. (Cr. 8vo, pp. 64. 3s. net.)

MEDICAL AND SURGICAL APPLIANCES.

Aseptic Dental Appliances.

MR. ROBERT M. CAPON, L.D.S., of Liverpool, President of the North Midland Branch of the British Dental Association, has designed an appliance for lessening the risk of infection through unclean dental instruments. The instruments for sterilization are arranged on trays fitting into a rack, which is placed in a perforated box having at each end a lug attachment for easy insertion, or withdrawal from the sterilizer. The appliance holds over 150 instruments, and for each set there is a special tray on which they remain until required for use. When a tray is removed from the rack the instruments on it do not come into contact with the surface of the cabinet or of the stand on which it rests. When large instruments, such as forceps, are to be boiled the perforated box is used alone. To secure continuity of asepsis through all operative dental work Mr. Capon has designed a simple form of instrument cabinet with more and larger working surfaces than is usual, all of which can readily be kept surgically clean. The instruments rest in the trays described above, and not in drawers as in other cabinets. A work bench is fitted at one end, and there is a disinfecting cupboard for holding face-pieces and other anaesthetic apparatus, while space is provided for the water sterilizer when not in use. All bottles are kept free from dust. The cabinet can be easily moved to whichever side of the chair is most convenient to the operator; and as both bracket and bracket table can be dispensed with, freedom of movement is secured. We understand that the cabinet and sterilizer will be demonstrated next month at the Odontological Section of the Royal Society of Medicine.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE SECOND APPEAL.

TO THE MEDICAL AND PHARMACEUTICAL PROFESSIONS OF GREAT BRITAIN AND IRELAND.

LADIES AND GENTLEMEN.—When at the close of 1914 the terrible plight of our professional colleagues in Belgium, overrun in circumstances of incredible brutality by the Germans, was brought to your notice, you responded generously to an appeal for the immediate creation of a Fund which should deal first with the grave necessities of those who had taken shelter with their families in this country, and secondly with the sufferings of those who remained in Belgium. The appeal of a committee representative of all sections of both professions was kept

⁴ *A Manual of Pharmacology and its Applications to Therapeutics and Toxicology*. By T. Sollmann, M.D., Professor of Pharmacology and Materia Medica in the School of Medicine in Western Reserve University, Cleveland. Philadelphia and London: W. B. Saunders Co. 1917. (Roy. 8vo, pp. 901; 29 figures. 20s. net.)

⁵ *Visits to Walt Whitman in 1890-1891*. By two Lancashire friends, J. Johnston, M.D., and J. W. Wallace. London: George Allen and Unwin. 1917. (Pp. 279; 20 illustrations. 6s. net.)

⁶ London: H. K. Lewis. Price 6d.

steadily before you in your professional journals, and the history and progress of the Fund up to February, 1917, which marked the opening of the third year of work, has been published as a pamphlet. This statement showed that by the first week in February, 1915, over £5,000 was received, and that by the end of the first year of working £18,570 has reached the treasurer's hands. Further sums afterwards brought the total up to £20,000 by the end of the second year of working. No appeals for subscriptions were sent out after the movement had been once inaugurated, and now the last financial statement shows that the Fund is practically exhausted.

Of the value that the Fund has been to those for whom it was created in the directions designated there can be no doubt, and we call your attention to the appended letter from Mr. W. B. Poland, who has had the closest personal experience with the lamentable position of our Belgian colleagues, and who writes movingly of what your practical assistance has done. To us it seems impossible that we should not attempt to continue the work.

The present position, however, is that without further large and prompt subscriptions to the Fund we shall be unable to keep up those substantial monthly subsidies to Belgium to which the money has been mainly devoted. We are fully aware of the burden which the medical and pharmaceutical professions of this country are bearing; we know that several funds which have the highest claims upon our purses are at the present moment seeking, and rightly expecting, widespread assistance; but we none the less urge that the money should be found for carrying on acts of mercy—or rather we should say of bare justice—towards the doctors and pharmacists of Belgium, the little country which with unexampled heroism stood between the German onrush and the civilization of Western Europe. Of the rightness of second appeal we know that no doubt can exist, nor of the good that your money has done; while to the manner of the distribution of the Fund we can point with legitimate pride. All our administration has been carried out gratuitously, and the expenses at the end of the first year were only £12 and at the end of the second year only £50. We direct attention in this connexion to the very special wording of the certificate given by Messrs. Crewdson, Youatt, and Howard after the examination of the accounts, with the books and vouchers of the Fund before them. This statement is also appended.

We beg, therefore, earnestly for immediate further subscriptions, that the benefits which we have been able to distribute for nearly three years may not suddenly cease at a time when they were never more urgently needed.

The address of the honorary treasurer of the Belgian Doctors' and Pharmacists' Relief Fund is Dr. H. A. Des Vœux, 14, Buckingham Gate, London, S.W., to whom all subscriptions should be sent. The honorary secretaries are Dr. S. Squire Sprigge, the *Lancet* Office, 423, Strand, London, W.C., and Mr. W. J. Uglov Woolcock, the Pharmaceutical Society, 17, Bloomsbury Square, London, W.C.

We are, ladies and gentlemen, your obedient servants,

RICKMAN J. GODLEE, Chairman,
President of the Royal Society of Medicine; late President
of the Royal College of Surgeons of England.
H. A. DES VŒUX, Honorary Treasurer,
S. SQUIRE SPRIGGE,
Editor of the *Lancet*.
W. J. UGLOV WOOLCOCK, Hon. Secs.
Secretary and Registrar of the Pharmaceutical
Society.

MEMBERS OF THE COMMITTEE.

Sir THOMAS BARLOW, Bt., late President of the Royal College of Physicians of London.
Sir W. WATSON CHEYNE, Bt., late President of the Royal College of Surgeons of England.
Dr. MEREDITH TOWNSEND, Representative of the Society of Apothecaries of London on the General Medical Council.
Sir ALFRED PEARCE GODD, late Vice-Chancellor of the University of London.
Sir FREDERICK TAYLOR, Bt., President of the Royal College of Physicians of London.
Dr. HERBERT SPENCER, Obstetric Physician to University College Hospital, London.
Dr. T. JENNER VIRGILL, Direct Representative for England on the General Medical Council.
Dr. F. M. SANDWITH, Gueham Professor of Medicine.
Mr. E. T. NEATHERCOAT, Vice-President of Pharmaceutical Society of Great Britain.
Dr. ALFRED COX, Medical Secretary of the British Medical Association.
Dr. DAWSON WILLIAMS, Editor of the *British Medical Journal*.
Mr. J. Y. W. MACALISTER, Librarian of the Royal Society of Medicine.

Dr. C. O. HAWTHORNE, representing the Royal Faculty of Physicians and Surgeons of Glasgow.
Mr. J. P. GILMOUR, Editor of the *Pharmaceutical Journal*.
Professor WILLIAM RUSSELL, late President of the Royal College of Physicians of Edinburgh.
Mr. J. W. B. HODSDON, late President of the Royal College of Surgeons of Edinburgh.
Dr. JOSEPH O'CARROLL, late President of the Royal College of Physicians of Ireland.
Dr. WILLIAM TAYLOR, late President of the Royal College of Surgeons in Ireland.

LETTER FROM THE DIRECTOR IN EUROPE OF THE COMMISSION FOR RELIEF IN BELGIUM.

3, London Wall Buildings, London, E.C. 2,
November 20th, 1917.

Dear Sir,—We wish to emphasize the claim that Belgium has upon all the friends in the outside world who are trying to relieve her continually increasing distress. In spite of all we can do, her position to-day is more perilous than it has ever been, and far from relaxing our efforts we must, with renewed energy, see to it that every possible means of tiding over the starvation and destitution there is made use of. The most difficult class to reach is the very class that your Fund in the past has ministered unto—namely, the families of the doctors and pharmacists who may not dig, to beg they are ashamed. If the supporters of your Fund knew how much actual suffering they had allayed, and how much potential, moral, and physical suffering they had prevented, they would not cease to continue their support, many as are the claims now made upon them. This office is a gulf into which pours the stream of Belgian misery, and it would not be difficult to supply you with hundreds of testimonials as to the state of things there, but any of them tells the whole story: "The misery has become terrible and increases every day. It pursues us wherever we go. In the streets we see the emaciated figures of our neighbours; eyes sad, heads lowered. One would think that the people had aged twenty years by reason of these unmerited calamities." Another message comes: "Life becomes mere suffering; no liberty, no food. We are chained and starved in one. For three years we have fasted to such a point that now we scarcely recognize one another. The times are indeed hard."

The people who receive your kindness and charity are grateful in the extreme. Wave after wave of gratitude sweeps over the country. Some day you will know of it. Finally, it is needless to say that all the charities in Belgium are well administered—there is no leakage by the way. Only those who deserve it get relief, and never more than they need. The funds from your society are paid over to a commission of eminent gentlemen of your profession and the distribution is under their personal supervision. The knowledge that their associates in England have not forgotten them is an inspiration to the whole profession at a time when moral support is perhaps as much needed even as food.

Faithfully yours,
(Signed) W. B. POLAND,
Director for Europe.

Dr. H. A. Des Vœux,
Honorary Treasurer of the Belgian Doctors' and
Pharmacists' Relief Fund.

The Auditors' Statement of the Present Position of the Fund.

TREASURERS' CASH ACCOUNT, JULY 1st TO NOVEMBER 30th, 1917.

July 1st, 1917.					
To balance ...	£5,477	13	4	By relief ...	£4,012 0 0
.. interest ...	34	0	7	.. clothes ...	10 10 0
				.. administration expenses ...	2 6
				.. balance	
				Cash at bank ...	1,489 1 5
	£5,511	13	11		£5,511 13 11

We have examined the above account with the books and vouchers of the Fund and certify it to be correct according to the books. In our opinion the receipts and payments have been fully recorded, and we have compared the receipts with the published acknowledgments and have had produced to us certificates as to the correctness of the balance as shown.

CREWDSON, YOUATT AND HOWARD,
Chartered Accountants and Auditors.
70A, Basinghall Street, London, E.C. 2, December 5th, 1917.

This pecuniary position corresponded with the estimate of the Committee, earlier in the year, that the funds in hand would enable a mensuality of £800 to be sent during 1917 to Belgium, but that the end of 1917 would see the practical exhaustion of the Fund.

SATURDAY, DECEMBER 29TH, 1917.

A MINISTRY OF HEALTH.

DURING the past two or three months the topic of a proposed Ministry of Health has shown no tendency to retire into the political background. This is a little surprising in view of the cold douche administered by the Premier on October 11th, when he told a deputation that a bill for this purpose could not be introduced in the midst of war. A week later the Chancellor of the Exchequer stated in the House of Commons that the subject had been carefully investigated and reported on by the Reconstruction Committee and by a Committee of Ministers, and expressed the pious hope that substantial agreement would shortly be reached amongst those directly concerned. For the time being the project seemed to be at a standstill; but recent events would suggest that it is very much alive. Thus, while the bill drafted by the National Insurance organizations has made little or no headway as a parliamentary measure, it has at least served to focus attention on the matter and to bring into view some of the opposing political and departmental forces which bar the way to action. This is equally true of the scheme outlined earlier in the year by the British Medical Association, and the two schemes have other points of resemblance. With the object of clearing the ground and possibly devising some mode of concerted action, joint sessions have been held between members of the Ministry of Health Committee of the Association and the promoters of the Approved Societies' bill, at which the clauses of the bill were examined, but it seems certain that neither scheme in its original shape would be accepted by Parliament as a non-contentious measure.

In the meantime there has been activity in many other quarters; in addition to meetings and sectional discussions up and down the country, several important public conferences have taken place in London under the auspices of such bodies as the Royal Institute of Public Health and the Faculty of Insurance. These were attended by spokesmen of the British Medical Association, and reports of the discussions have appeared in the JOURNAL. Special interest attaches to Dr. Addison's address at the conference in the Central Hall, Westminster, on November 24th, in the course of which he announced that the Cabinet had instructed him, as Minister of Reconstruction, to study the whole question of a Ministry of Health, with a view to bringing about agreement between the parties interested and formulating a plan. This amplified Mr. Bonar Law's previous statement that the Reconstruction Committee had taken the matter in hand. Dr. Addison has now made the first practical step towards the accomplishment of his purpose by getting into touch with the Ministry of Health Committee of the British Medical Association. Needless to say, its advice and criticism will be freely at his disposal if, as we assume to be the fact, an undertaking can be given that the Government is not as yet committed to any definite line of policy. Unfortunately, just at the moment when a steady public opinion was especially needed, one of the daily papers startled its readers with a

string of irresponsible guesses. It may be hoped that the prompt official denial was in time to undo most of the mischief; but a *canard* is always hard to shoot down once it is well on the wing.

As the year draws to a close it becomes more and more plain that an agreed measure alone has any chance of reaching the Statute Book. The war has passed into its most critical phase. Cabinet and Parliament alike are engrossed in economic and military problems, upon the right solution of which our national future depends. Reform of public health administration is admitted on all hands to be long overdue; but whereas the war has accentuated the urgency of this demand, nothing will be done about it in war time unless rival interests agree to sink their differences and unite upon a common minimum programme. At the moment there would seem to be some chance of such a compromise. The first question to be asked is whether it is in the public interest that a partial and preliminary measure should be enacted, straightening out some of the tangle at the centre, while leaving the periphery untouched at the outset. We conceive that the majority of the medical profession, when the alternatives are put before it, will be inclined to support a policy of compromise upon matters of detail, method, and procedure—provided no big principle is yielded—rather than that all reform should be shelved; but there is, on the other hand, force in the plea which the Council of the Royal Sanitary Institute has entered in favour of fuller consideration, for there are historical grounds for fearing that an incomplete scheme when it gets into the hands of departmental officials may be whittled away to nothingness.

As to the real intentions of the Government nothing is known, and probably the Cabinet is waiting to see whether the force of public opinion is sufficient to calm the contending parties. Rumour, indeed, unkindly suggests that the various interests are being brought together at the Ministry with the object of playing them off against each other. It may be so: such things have happened before. But we can well believe that Dr. Addison himself would like to present to Parliament early in the New Year an agreed bill for setting up at once a Ministry of Health, with enabling clauses for future development, both central and local. His own view may be judged from a passage in his speech, to which allusion has been made above, where he said that while the first thing to aim at was to get the general plan right and the central executive department constituted on right lines, it was to be wished not that everything should be done by a department in Whitehall, but that a large measure of decentralization of control should be worked out. The first duty of the new Ministry would be to evolve a proper health plan and policy; the need of the moment was, he thought, to get that body created.

As we pointed out on October 27th, the danger inherent in a measure which refrains from dealing by direct legislation with some of the most important and urgent branches of health reform is that the Minister might become an absolute autocrat in all health matters, with the future of the general medical profession in the hollow of his hands. If events are moving towards the formation of a Ministry of Health, the Committee of the British Medical Association, which holds a watching brief for the profession, will, we do not doubt, take a firm stand upon the principle that the Central Advisory Council within the Ministry must have real power and adequate medical representation. For instance, without a statutory right to report to Parliament any serious

disagreement with the Minister on fundamental questions, the Advisory Council would have little real influence. We understand that this point has already been put before Dr. Addison. With a principle of this kind at stake, it is essential that those who speak on behalf of medicine should feel that the profession appreciates the issues and is solidly behind them. But if this demand is conceded—even though to do so would involve a break with precedent—many complicated questions will remain for adjustment. To take only one instance: it is far from easy to decide which of the existing functions of the Local Government Board ought to be taken over by a Ministry of Health. All are agreed that housing is closely related to health, but the term is vague, and a working definition is needed before housing is included among the duties of a new central health authority.

If a Government bill for a Ministry of Health should take shape early next year, the time for effective criticism and action may be short. The medical profession must therefore keep its attention fixed on this subject. As Dr. Johnson once said in the course of a famous argument: "Depend upon it, Sir, when a man knows he is to be hanged in a fortnight, it concentrates his mind wonderfully."

ENGLISH PIONEERS IN NAVAL MEDICINE.

A SEAFARING nation like the British was naturally confronted early in its naval development with the problems of disease as they affect men who go down to the sea in ships. The subject did not escape the far-seeing mind of Richard Hakluyt, or Hacklewit as his name was generally pronounced and often spelt by his contemporaries. He was not a medical man, but a clergyman: though he modestly called himself simply a "preacher" he was Archdeacon of Westminster and Chaplain of the Savoy. The tercentenary of his death fell on November 23rd of last year. From his boyhood he had been fascinated by the "sweet studie of the historie of cosmographie," and he had a prophetic vision of the important part to be played by tropical disease in colonial expansion, or "plantation" as it was called in his day. In his dedication to Sir Robert Cecil of the third and last volume of the *Voyages, Navigations, Traffiques and Discoveries of the English Nation*, published in 1600, he refers to an essay on naval hygiene which is probably the earliest English work on the subject. This is a treatise by George Whetstone, which was not long ago unearthed and reproduced in facsimile by Dr. Charles Singer.¹ Notices of the little work appeared in the *BRITISH MEDICAL JOURNAL* of November 23rd, 1912 (p. 1481), and November 13th, 1915 (p. 730). Hakluyt says: "I was once minded to have added to the end of these my labours a short treatise, which I have lying by me in writing, touching *The Curing of hot diseases incident to travellers in long and Southerne voyages*, which treatise was written in English, no doubt of a very honest mind, by one M. George Wateson and dedicated unto her sacred Maiestie. But being carefull to do nothing herein rashly, I showed it to my worshipfull friend M. doctor Gilbert, a gentleman no less excellent in the chiefest secrets of the Mathematicks (as that rare jewel lately set forth by him in *Latine* doth evidently declare) than in his own profession of physicke: who assured me that it was very defective and imperfect, and that if hee might have leisure, which

that argument would require, he would either write something thereof more advisedly himselfe, or would conferre with the whole Colledge of Physicians, and set downe some order by common consent for the preservation of her Maiesties subiects." Whetstone was a gallant and a poet who had seen much of foreign parts, and in his travels had picked up some notions of naval medicine. But he was not a doctor; it is no wonder, therefore, that his work was defective and imperfect. William Gilbert, on the other hand, was the foremost scientific man of his time, and the advance of knowledge was greatly delayed by the fact that his scheme never reached fulfilment. Nearly a century had to elapse before there appeared a work entitled *An Account of the . . . Distempers that are incident to seafaring people With observations on the diet of Seamen in His Majesty's Navy*, by the "Physician to the Blue Squadron of His Majesty's Fleet" (London, 1696). Gilbert seems to have been in high repute for his knowledge of the diseases of seamen. In a recent paper giving an account of his life and work Dr. Singer² quotes the following entry from the Acts of the Privy Council under date March 22nd, 1588, when the navy must have been anticipating the arrival of the Armada which appeared off our coasts a few months later: "Whereas a dysease and sickness began to encrease in her Majesties Navye, for remedie of the dyseased and for staie of further contagion their Lordships thought meet that some lerned and skillfull phisicians should presently be sent thether; and for that their Lordships hard that good reporte of the sufficiency learning and care of Dr. Gilbert, Dr. Marbeck, Dr. Browne, and Dr. Wilkinson, as they were thought very fytte persons to be employed in the said Navye to have care of the helthe of the noblemen, gentlemen, and others in that service," therefore these physicians were required "to put themselves presently in a readynes to goe downe to the Navye, and to carry with them a convenyent quantytie of soche drogues as should be fyt for medycine and cure; and uppon their repaier and conference with the Lord Admyrall soche order should be taken for their entertainment as should be to their contentement." It would be interesting to know if this scientific mission was ever accomplished, and, if it was, what came of its work.

If Gilbert must share with others the glory of creating naval medicine, he stands alone in fields of scientific exploration which have been of incalculable advantage to mankind. He was referred to by Sir Thomas Barlow in his Harveian Oration last year as a pioneer in the study of magnetism, but he is more adequately described in the *Encyclopaedia Britannica* as the father of electric and magnetic science. His book, *De Magnete*, is the record of eighteen years of patient experimental work, and contains a great number of important observations on the properties of the magnet. He framed a theory to explain magnetic deviation, investigated the dip of the compass needle, and propounded a method of determining latitude by its means. He was the inventor of two instruments designed to enable seamen "to find out the latitude without seeing sun, moon, or stars." He founded the science of electricity, and placed it on a solid basis of experimental fact. He also did much work in chemistry but the records of his experiments have, unfortunately, been lost. He had a hand in the preparation of the first British pharmacopoeia, although the work did not see the light till after his death. This was a misfortune, for he hated everything savouring of quackery, and it can hardly be doubted that his

¹ *The Cures of the Diseased in Foryaine Attempts of the English Nation*. By George Whetstone. London, 1598. Oxford, 1915.

² *Journal of the Royal Naval Medical Service*, October, 1916.

influence would have prevented the inclusion of much fantastic and foolish stuff which found its way into the work. Summing up Gilbert's scientific achievement in addition to his pioneer work in electricity and magnetism, Silvanus Thompson¹ says: "He also made notable contributions to astronomy, being the earliest English expounder of Copernicus. In an age given over to metaphysical obscurities and dogmatic sophistry, he cultivated the method of experiment and of reasoning from observation, with an insight and success which entitles him to be regarded as the father of the inductive method. That method, so often accredited to Bacon, Gilbert was practising years before him."

This remarkable man came of a family which was probably connected with Sir Humphrey Gilbert, the famous explorer and half brother of Sir Walter Raleigh. He was born at Colchester in 1544, and educated at St. John's College, Cambridge, of which he became a Fellow and mathematical examiner. He took the degree of M.D. in 1569. He then spent some years in travel abroad, visiting Italy, where he made the acquaintance of Giordano Bruno, the martyr of free thought, Sarpi, and probably Galileo. On his return to England he settled in London, where he practised his profession with great success. He lived on St. Peter's Hill, between Upper Thames Street and Little Knight-bridge Street, where he used to gather together a society or college of men interested in the study of nature. This, Dr. Singer says, may be regarded as the earliest scientific association in England, and perhaps in Europe. Gilbert was successively censor, treasurer, and president of the Royal College of Physicians. In 1601 he was appointed physician to Queen Elizabeth, who trusted him as a doctor, and appreciated his work as a scientific investigator. How genuine was her appreciation is proved by the fact that, although by no means liberal in the matter of money, she gave him a pension to help him in the prosecution of his researches. Gilbert attended Elizabeth on her deathbed in 1603 and was appointed physician to her successor. He lived only a few months afterwards, dying, probably of the plague, towards the end of 1603.

The medical profession may well be proud of this great scientific pioneer. His name is immortal in the truest sense, for as Dryden sang—

Gilbert shall live till loadstones cease to draw
Or British fleets the boundless ocean awe.

SANITARY ARRANGEMENTS IN TUBE SHELTERS.

DURING the air raid on London on December 18th some 250,000 people found shelter in the underground stations of the tube railways. From the fact that three and a half hours elapsed between the warning and the "all clear" signal, and that many of the refugees must have been some while longer in the tubes, it is evident that very effective sanitary organization is necessary to cope with such an emergency. The number of tube stations which are underground in the sense that the platforms are reached by lift or escalator is between ninety and one hundred, and in all cases the permanent lavatories and urinals are situated either at street level or a little below it. It has been necessary to put up temporary conveniences, if possible near the platforms, but the exact situation must vary with the structure of the station. If this provision were not made, we are assured by the tube authorities that the conditions would be unspeakable, since it is well known that in nervous subjects excitement or shock may provoke the act of defecation. These temporary conveniences are installed, supervised,

and cleared by the sanitary authority of the particular borough council in whose area the station is situated. The tube management has no responsibility for them; they are wholly a municipal matter. The removal of litter, however, is carried out by the station staff, and is very efficiently performed, especially in view of the fact that many of the people bring with them supplies of food. The atmosphere of the tube is inevitably close during the actual period of congestion, but the tube management point out that five of the railway systems are of very recent construction, and that in these the engineers had the advantage of applying such principles of underground ventilation as experience had shown to be desirable; while as for the older systems, the largest of these, the Central London Railway, is ventilated, alike in the stations and the tunnels, by means of the ozonair installation. At all events, no special measures have been found necessary as yet to purify the air after a raid night. Since the series of raids at the end of September the St. John Ambulance Brigade has provided a staff to attend to cases of fainting and illness in the tubes during raids. Even when there is no damage in the immediate locality the first-aid staffs find their hands sufficiently full with people who are suffering from shock and exhaustion. At Finsbury Park station on two consecutive nights 300 such cases were dealt with, although very often all the first aid that is necessary is a mug of water. The principal stations are now manned by the brigade when a raid is expected, and the borough councils also dispatch a number of women lavatory attendants. Where possible, an unused lift or storeroom is placed at the disposal of the St. John men. Although fatalities have not been unknown since the public began crowding into the tubes, the fewness of the serious casualties under these unusual circumstances reflects great credit alike upon the tube management, the ambulance service, and the police.

THE TYPHOIDIN TEST.

THE original technique of Gay and Force's typhoidin test, or skin reaction indicative of immunity against typhoid fever, consisted in the application of a killed concentrated old glycerin broth culture of a single strain of the *Bacillus typhosus* to the slightly abraded surface of the arm. A positive reaction was distinguished from a negative result by a quantitative difference in millimetres in the diameter of the areola appearing round the abraded surface after twenty-four hours. By means of this test it should be possible to determine if a person previously inoculated against typhoid fever has outgrown the protection and therefore should be reinoculated. Since it was first described in 1914 the technique of the test has been considerably modified and improved; thus Force and Stevens¹ use a multivalent preparation from ten strains of *B. typhosus*, so as to allow for the probable varieties and the corresponding antigenic differences, inject a dried typhoidin powder intradermically in the minimal effective dose (0.00002 gram in 0.05 c.cm. of 0.5 per cent. carbolated saline), and read the result of the test forty-eight instead of twenty-four hours later. The prolongation of the interval is advisable, as it eliminates the non-specific irritative reaction which may occur in normal persons from the proteins of the culture media and from the carbolic acid used in the injection. In these conditions a positive reaction is shown by the presence, forty-eight hours after the application of the test, of a maculo-papule with a definite erythema at least 5 mm. in one diameter, a doubtful reaction by the absence of either induration or erythema, and a negative reaction by the absence of both after forty-eight hours. Out of 18 normal persons 17 gave a negative typhoidin reaction, and out of 26 persons with a history of typhoid fever 19 gave a positive reaction. It appears that typhoid immunity is less stable than is often supposed—50 per cent. of persons

¹ Gilbert of Colchester, *Father of Electrical Science*. London, 1903.

¹ J. N. Force and I. M. Stevens: *Arch. Int. Med.*, Chicago, 1917, xix, 440-456.

vaccinated against the disease three years before, 45 per cent. of those vaccinated two years, and 27 per cent. of those vaccinated one year previously gave a negative reaction. The routine administration of three doses of typhoid vaccine is in many instances insufficient to produce sensitization to the typhoid protein, and presumably therefore protection against the disease. In support of the contention that this test shows whether or not an individual is protected against typhoid fever, Gay and Lamb² point out that no person giving a positive reaction has subsequently developed the disease, that individuals who react positively, when reinoculated with typhoid vaccine, react much more violently than persons giving a negative reaction, in this respect resembling typhoid recoveries, and certainly indicating a reaction and probably protection against *B. typhosus*, and that persons inoculated against typhoid who give a negative typhoidin reaction become in most instances positive after further inoculation. The value of the test, in deciding on the desirability of antityphoid vaccination or its repetition, therefore appears to be established.

THE UTERUS REMOVED BY CAESAREAN SECTION.

OBSTETRICIANS should not fail to see the November number of the *Bulletin* of the Johns Hopkins Hospital, which contains an article by Professor Whitridge Williams on the examination of 50 uteri removed by subtotal hysterectomy immediately after Caesarean section. Apart from the respect with which all the writer's work is received in this country, this paper is of special interest on account of the fine material upon which the observations contained in it are based, and from the fact that it tends to alter in some degree the views on certain points hitherto accepted and incorporated into teaching. In the 50 uteri examined the placenta was attached to the anterior wall in 18 instances, and to the posterior wall in 32. The condition of the decidua at term was very variable, not only in different uteri but even in different parts of the same uterus. In some it was thick, in others thin; in some it consisted mainly of the compact layer, in others the spongy glandular structure was the more extensive. The line of separation of the placenta was found to be more often through the spongy layer, but sometimes through the compact and sometimes quite indiscriminately and irregularly through both. In one instance the decidua basalis was almost entirely absent, the chorionic villi being separated from the muscular wall by a thin layer of canalized fibrin only. Would this, one wonders, have been a case of "adherent placenta" if labour had occurred *per vias naturales*? Professor Whitridge Williams's specimens give no definite proof of the method of separation of the placenta, but the festooning and wrinkling of the fetal membranes, which is beautifully shown in his sections of the wall of the recently emptied and retracted uterus, suggest in no uncertain way that it is more likely to be caused by the disproportionate shrinkage of the placental site than by the occurrence of retroplacental haemorrhage. After describing the large cells, almost certainly of chorionic origin, so frequently found deep in the uterine wall at the placental site, Professor Williams goes on to describe certain degenerative changes in the vessels of the placental site, which he seems to regard as characteristic of this area. The nature of these changes he hesitates to specify. Incidentally he gives the *coup de grâce* to the expiring theory that thrombosis of the vessels in the placental site was a normal precursor of labour, and one factor in preventing haemorrhage during the third stage. The last, and perhaps the most important, observation refers to the scar in the uterus after a previous Caesarean section. Where the operation is followed by a normal afebrile puerperium the scar is recognizable on the outer and inner surfaces of the uterine wall only. There is no scar tissue in the wall itself and muscular

fibres run across the site of incision as freely as elsewhere. In cases where the previous operation had been followed by wound infection, the wall in the region of the scar was excessively thinned. There is therefore no inherent reason, as far as the uterus is concerned, why a woman who has had a Caesarean section and made a perfect recovery should not subsequently be able to deliver herself. The paper is very well illustrated, and will afford food for reflection to practitioners as well as to all teachers of obstetrics.

EMBRYOMAS IN PLANTS INDUCED BY BACTERIAL INOCULATION.

AMONG the interesting addresses given by Sir James Paget one of the most attractive is that on elemental pathology delivered at Cambridge in 1880 and devoted to vegetable diseases, which he had studied as a hobby in what he called "the idleness of vacations." When preparing this address he nearly abandoned the subject when he found the vast amount of good scientific work that had already been done even then on the subject. Since then further researches have gone on, but most medical men do not see the periodicals in which the reports appear, and on this account the easily available article by Erwin F. Smith¹ is most welcome. Working in the laboratory of plant pathology, Bureau of Plant Industry, U.S. Department of Agriculture, Washington, D.C., he has, with his co-workers, produced since 1906 hundreds of crown galls on various plants by inoculation of pure cultures of a white, rod-shaped, polar flagellate schizomycete. The crown gall is a tumour common in wild and especially in cultivated plants, and is analogous to a sarcoma. When the connective tissues only of the plant are stimulated by inoculation of cultures of the *Bacterium tumefaciens* this crown gall develops; the parasite, which is intracellular and not very abundant in the tumour, does not destroy the cells, but stimulates them to abnormal growth by means of its diffusible products. A new and remarkable result has been obtained by introducing pure cultures of the micro-organism by needle pricks into the growing tissues of susceptible plants in the neighbourhood of the totipotent or pluripotent cells, which may be either dormant axillary buds or meristematic cells remote from the leaf axils; these cells begin to grow, and a complex tumour or embryoma results. These embryomas, which are produced as readily as the ordinary crown galls by inoculation in a different site, contain sarcomatous tissue and rapidly developing abortive parts of the young plant roots, stem, leaves, and flower buds, or cells with floral pigment. The organs or tissue fragments in these atypical teratoid tumours are poorly vascularized, abort at various stages, usually early in development, and the organs or fragments of organs are often monstrous, simplified, reduced, reduplicated, and invaded by sarcoma. These experimental embryomas have been obtained in fifteen different families of plants. Whether or not carcinoma can also be produced in plants by bacterial inoculation remains to be proved; but as the author has obtained the first stages of cell division in the epidermic cells by bacterial infection he anticipates that further research will give an affirmative answer. The tumours, common on clus and apple trees, called cankers, and due to injury, present considerable superficial resemblances to human cancer, but, as Sir James Paget pointed out, are more closely allied to cheloids.

PNEUMOCOCCIC INFECTION IN MENINGOCOCCIC MENINGITIS TREATED BY SERUM.

DURING the first four months of the year the cases of cerebro-spinal fever in Paris showed an extraordinary high incidence of secondary pneumococcic infection. Thus in February, when this somewhat unusual complication was first noticed, Netter and Salanier² stated that out of 300

²F. P. Gay and A. R. Lamb, *Journ. Lab. and Clin. Med.*, 1917, ii, No. 4.

¹E. F. Smith, *Bull. Johns Hopkins Hosp.*, Baltimore, 1917, xxviii, pp. 277-294.

²Netter and Salanier, *Bull. et mém. Soc. Méd. des Hôp. de Paris*, 1917, 3 ser., tome xli, p. 239.

cases of meningococcic meningitis there had been four examples of this complication, three of which had occurred in that month, and argued that as primary pneumococcic meningitis had been much more in evidence since December, 1916, the virulence of the pneumococcus had increased. In a more recent communication¹ these writers tabulate 22 cases of secondary pneumococcic infection of meningococcic meningitis treated by serum in the first four months of the year, and mention that among 73 hospital cases of proved meningococcic meningitis 17 (which are included in the 22 quoted above), or 23.3 per cent., showed this secondary invasion. The pneumococcic infection usually occurs comparatively late, and may do so when recovery appears to have begun; in most instances a primary focus is absent and infection is presumed to have spread from the nasopharynx. Diminished resistance due to meningococcic infection, and probably the injection of large quantities of serum intrathecally, favour the occurrence of this complication. The prophylactic injection of 2 or 3 c.cm. of antipneumococcic serum with the anti-meningococcic in 25 cases appears to have diminished both the incidence and, in the two cases in which secondary infection occurred, the severity of this complication, as the two cases recovered.

TACHYPHYLAXIS AND ITS THERAPEUTICAL APPLICATIONS.

TACHYPHYLAXIS, or rapid immunization, is the term used to describe the phenomenon that the effects normally produced by the intravenous injection of certain substances can be prevented by the previous injection of a quantity of the same substance so small that it need not have the usual action, and that this change occurs in a few minutes. Although Gley and Champy, the inventors of the word in 1911, observed this in connexion with albumose, a minute dose preventing the anticoagulating effect of a subsequent injection, in most cases the important factor in tachyphylaxis appears to be that the blood is rendered incoagulable by the first and small intravenous injection, and that in this way bad effects, commonly due to intravascular clotting, caused by ordinary injections of the substances in question, are obviated. This applies to arseno-benzol, sodium nucleinate (used in paralysis agitans), and chaulmoogra oil, which have been shown to induce tachyphylaxis both in animals and man. Busquet² points out that in view of its possible practical application in medicine the subject of tachyphylaxis should be more widely known to the medical profession. Thus it can be utilized in the transfusion of defibrinated blood; the toxicity of defibrinated blood, pointed out by Magendie, has been shown to depend on intravascular clotting, which, as Hédou has proved, can be obviated by the tachyphylactic effect of a preliminary small injection of defibrinated blood. Similarly, Busquet argues that a corresponding procedure should be successful in the case of intravenous injections of the extracts of the ductless glands. On the other hand, he found that the preliminary injection of a small quantity of colloidal gold in typhoid fever and of colloidal sulphur in rheumatism did not fulfil the expectation that it would abolish the fever and other unpleasant symptoms produced by the ordinary injection.

THE "HIDDEN SCOURGE" IN MEDIAEVAL PARIS.

DR. HENRI BOUQUET has unearthed an interesting historical document³—a decree of the Paris Parlement of March 16th, 1496, relative to the prevention of the "great pox." It is interesting to note that the date of this decree is only four years later than the discovery of the New World by Christopher Columbus and the supposed importation of the scourge into Europe. It sets forth that for two years the disease had raged in Paris and other places in France,

wherefore the Reverend Father in God, the Bishop of Paris, in association with certain royal officials, was commissioned to devise measures for checking the scourge. A proclamation was to be made by the public crier in the King's name that all men and women suffering from the disease who were not residents of Paris when attacked should, within twenty-four hours, go forth from the city to their native place or elsewhere, as they thought fit, under penalty of the hangman's rope. To facilitate their departure all such persons were to be given four *sols parisis* as they passed out by the gate of St. Denys or St. Jacques with a strict injunction not to return till they were completely cured. Paris residents were to be confined to their houses and forbidden to go about the city under a like penalty; if they were indigent, they could, on the recommendation of their parish priests or churchwardens, be supplied with suitable provisions. Such poor persons as had no home to go to were to be isolated in houses hired for the purpose in Saint-Germain des Prez, and were to be supplied with food and other necessities, but were forbidden to go into the city till their cure was complete. Women were sheltered in separate quarters. When accommodation in these houses was inadequate, the patients were placed in barns and other buildings hired at the expense of the city. The patients were not allowed to hold any communication with people outside; breach of this regulation was punished by imprisonment and corporal punishment. This ordinance could not have been very effective, for on June 25th, 1498, the prohibitions were reissued under the penalty of being cast into the river. This appears to be the first attempt to found special establishments for the segregation of syphilitics. It thus marks a date in the social history of venereal disease, but it may also be taken as a record of the first failure of legislative repression.

THE LATE COLONEL HENDLEY.

THE late Colonel Thomas Holbein Hendley, C.I.E., I.M.S., of whose life and career a full account was published in the *BRITISH MEDICAL JOURNAL* of February 10th, 1917, p. 211, was a notable example of successful devotion to what Lieut.-Colonel D. G. Crawford in his monumental *History of the Indian Medical Service* denominates "extra-professional work" (Vol. ii, Chapter XXIX, p. 139). Crawford gives in this chapter an admirable summary of contributions to exploration, science, philology, and literature which have been made by officers of the Indian Medical Service. A brief note under the head of "Art" refers to Colonel Hendley's fruitful study and exposition of every variety of Indian artistic handiwork. This phase of Hendley's most devoted and meritorious labour is presented in greater detail in a very excellent and appreciative memoir published in the November, 1917, number of the *Journal of Indian Art and Industry*, in the founding and conducting of which he took a prominent and very willing part. Most of the Indian medical officers who have undertaken "extra-professional work" have abandoned their medical duties in pursuit of their hobbies; but it was far otherwise in Hendley's case. During his long service in Central India and his subsequent tenure of administrative office in the North-Western Provinces and Oudh and in Bengal, he practised his profession with zeal and success, and suggested and promoted means and measures for extending the benefits of medical treatment among Indian peoples. He also acted as a volunteer surgeon, and was an Honorary Associate and Knight of Grace of the Order of St. John of Jerusalem; he furthered the objects of the order by his instrumentality in introducing the elements of first aid and hygiene into schools and into the examinations of the Calcutta University. His art pursuits were mainly carried out while he served for a period of twenty-three years as Residency Surgeon and Administrative Medical Officer in the Jeypur State. He was fortunate in obtaining the warm countenance and aid of an enlightened ruler and in finding

¹ Bull. et mèm. Soc. Méd. des Hôp. de Paris, 1917, 3 sér., tome xli, p. 89.

² H. Busquet, *Presse méd.*, Paris, 1917, xxv, 605-7.

³ *Paris médical*, September 29th, 1917.

a nucleus for his art essays in the productions of Jeypur artificers. The Jeypur Museum remains as a permanent monument of his devotion to the study of Indian art and industry, of which the notice under reference supplies a very complete and highly laudatory record.

THE MOTOR SPIRIT RESTRICTION ORDER.

It was announced in the SUPPLEMENT of last week that the motor car badge for members of the British Medical Association is now ready for issue, on the distinct understanding that those to whom it is supplied will only use it when their cars are engaged on professional or other purposes expressly authorized by the Motor Spirit Restriction Order No. 2 of 1917, and that the Association takes no responsibility for improper use of the badge. In this connexion it may be well to draw attention to two recent prosecutions of medical men under the Defence of the Realm Act for using their motor cars in other than a professional capacity. In the first case, at Leeds, the practitioner put in the plea that on the occasion in question he drove his family to an hotel for a dancing lesson which had been prescribed for one of his daughters after an illness, and that he then went on his professional round. The police superintendent in his evidence said that a Home Office instruction laid it down that the carrying of a passenger by a driver engaged on legitimate business did not by itself constitute a breach of the Motor Spirit Restriction Order. He stated further that this was the first case of the kind in Leeds, and the prosecution was undertaken as a warning. Having regard to the ruling by the Home Office that a medical man could fill a car on his rounds, the magistrate did not think it was always incumbent on a practitioner to go by the shortest route to his business, and dismissed the case. In the second prosecution, at Marylebone, the medical man was less fortunate. His defence was that he called at Baker Street station to pick up a lady who was both a patient and his fiancée. The magistrate remarked that the visit was not a professional one on that occasion, and imposed a fine of £1. It is evident that doctors will have to use considerable discretion in giving lifts to their families or friends, since the onus will be upon them to satisfy the authorities that the car is being used at the time for an authorized purpose.

THE HALF-YEARLY INDEXES FOR 1917.

THE usual half-yearly indexes to the JOURNAL, to the EPILOGUE, and to the SUPPLEMENT, have been prepared, and will be printed. They will, however, not be issued with all copies of the JOURNAL. Any member or subscriber who desires to have one or all three of the indexes can obtain a copy of what he wants post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association, 429, Strand, W.C.2. Such copies will be dispatched shortly after the middle of January.

Medical Notes in Parliament.

Insurance Amendment Bill.—The National Insurance (Amendment) Bill passed through the report stage and was read a third time in the House of Commons on December 18th. A few amendments to the financial clauses were adopted, and to Clause 13 a fresh subsection was added as to women's benefits. This laid down that, notwithstanding any provisions to the contrary in any rule of an approved society, an insured unmarried woman who was pregnant should not on the ground that her pregnancy was due to misconduct be deprived of any sickness or disablement benefit to which she would but for that provision have been entitled.

Medical Examination by National Service Boards.—Mr. Beck (Parliamentary Secretary to the Ministry of National Service) informed Mr. Gilbert that it was not the case that

men medically examined by National Service Boards were refused information as to the grades in which they were placed. Every man fit for any form of military service received a card (M.N.S. Form 3291) on which his medical grading was plainly stated—Grade 1, Grade 2, or Grade 3, as the case may be. Every man found to be totally and permanently unfit for military service received a certificate (M.N.S. Form R. 2079) discharging him from all further liability to military service.

Junior Army Officers' Pay.—On questions by several members, Mr. Bonar Law expressed regret that he could not announce the decision on the subject of the pay and allowances of junior commissioned officers. The Cabinet Committee had been sitting almost daily, and it was not a very easy matter to solve.

Red Cross Workers in France: Combing Out.—Mr. Beck, in answer to Colonel Faber, said that the total number of men of military age employed by the British Red Cross Society in France was stated by the society to be approximately 1,900. On representations made in June, a proportion of these men were being withdrawn for service in the armed forces, on the principle that men fit for general service, and men of category B1 under 30 years of age should be released, subject to appeal by the society to Sir Douglas Haig in very special cases of indispensability. The society further stated that there were also approximately 200 men of military age similarly employed in other theatres of the war. In Great Britain, excluding tribunal cases, there were approximately 250 men of military age employed by the society; only two were fit for general service. In addition to the above there was a certain number of men of military age who had been granted exemption by the tribunals in the ordinary course, and who had undertaken either whole or part time under the British Red Cross Society. Mr. Beck added that some of the men had been in the Red Cross Society from the beginning and were very valuable, but combing out was being done.

Grants for Auxiliary Hospitals.—In reply to Sir William Collins, Mr. Forster said that the increased grants in aid of auxiliary hospitals, Classes A and B, of 3s. 3d. and 2s. 6d. respectively (maxima), took effect from August 1st. Established civil hospitals were in receipt of grants on a different scale, and the question of increasing those grants was under consideration. Sir William Collins asked when the additional grants to those hospitals voluntary before the war which were now receiving only 4s. a head for military cases would be announced. Mr. Forster took the reference to be to the large hospitals, such as the London. He hoped there would be no undue delay; the question of increasing the grant was now under consideration.

Training Centres for Discharged Soldiers in Ireland.—Sir A. Griffith-Boscawen informed Mr. Hogge that in Dublin training was in operation in optical and astronomical instrument making, basket-making, carpentry, toy-making, gardening, care and management of horses, clerical work, manufacture, etc., of artificial limbs, pipe-making, and motor mechanics. In Belfast there was training in commercial subjects, and courses had been sanctioned, but were not yet in operation, for cane-chair seat making, French polishing, and domestic assistance in hotels. Schemes for instruction in boot repairing and box-making were under consideration.

Small-pox in the Army and Navy at Home.—In reply to Mr. Benthall, Mr. Macpherson said that the number of cases of small-pox in the army notified in England and Wales during 1916 was ten. Of these, six were unvaccinated—five of them recovered and one died. Three were vaccinated in infancy—two of these recovered and one died. One who was revaccinated at the age of 14, and fourteen years before the attack, recovered. Dr. Macnamara, in answer to another question by Mr. Benthall, said that one case of small-pox occurred amongst sailors in the navy last year. The man recovered; particulars were not available as to vaccination or revaccination. The man, being a stoker in the Royal Naval Reserve, was liable to be vaccinated or revaccinated as a condition of entry into the service.

The Cost of Living.—Mr. Herbert Samuel asked a question as to the cost of living, the Food Controller being reported to have said on December 18th that it had gone down by something like 10 per cent. in the course of the last six months, while the figures published in the *Labour Gazette* for December purported to show that in the same period the cost of food had increased by 3 per cent. Mr. Law said he was strongly of opinion that, if possible, a reliable estimate of the increase in the cost of living should be obtained. The Government were now considering whether or not an inquiry such as had been recommended by the committee of which Mr. Samuel was chairman should be made.

Neurasthenic Soldiers.—Mr. Hugh Law asked Mr. Forster whether before soldiers who had been invalidated suffering from shell shock or other nervous troubles were sent back to the front they were examined by a medical board containing at least one specialist in nervous diseases. Mr. Macpherson: I cannot give the assurance at present, but under the new arrangements it is hoped that this desirable end will be obtained.

THE WAR.

GUNSHOT WOUNDS OF THE HEART.

STABSARZT PROFESSOR REHN¹ has recorded three cases of wound of the pericardium and heart.

CASE I.

The patient had received several shrapnel wounds of the left side of the body, one of which showed an aperture of entry just above the left nipple, with no aperture of exit. The cardiac area was normal on percussion. There was a small area of dullness over the postero-inferior part of the left lung, with feeble breath sounds and diminished vocal fremitus. Marked pericardial friction was audible over the sternum. The pulse was small and rapid, the breathing shallow and laboured. The diagnosis made was wound of the pericardium, the projectile being lodged in the left lung. Under expectant treatment the symptoms disappeared in the course of a few weeks, with the exception of shortness of breath on exertion.

CASE II.

The patient had received a shrapnel wound of the right side of the thorax twenty hours previously. The aperture of entry was two fingerbreadths from the left border of the sternum and one fingerbreadth below the horizontal nipple line; there was no aperture of exit. The fifth costal cartilage comminuted. Cardiac dullness was increased laterally to the right, especially towards the base of the heart. The heart sounds distant; there were no friction sounds. The pulse was rapid and irregular. X rays showed a large fragment in the pericardial sac. An operation was performed under pressure; a costo-xiphoid incision was made beginning at the left costal arch and extending upwards two fingerbreadths above the aperture of entry; the sternal end of the fifth rib was resected together with 5 cm. of the sixth and seventh ribs. A fragment of shell, measuring 4.5 by 2 by 0.8 cm., was found lodged in the parietal pericardium and projected 1 cm. into the pericardial cavity; on removal of this a large quantity of blood-stained fluid was discharged. On enlarging the pericardial wound upwards it was found that the apex of the heart was superficially wounded, but haemorrhage from it had ceased. There was also a wound of the left pleura. The wounds in the pleura and pericardium were sutured, a drainage tube being inserted into the lower part of the pericardial sac. A suction apparatus was adopted for removal of the exudate from the pericardium, and air was excluded by means of an india-rubber plate. These measures were not completely efficient, chiefly owing to the loss of substance at the external wound, and on the following days a putrid, haemorrhagic pericarditis developed, terminating fatally in profuse haemorrhage on the eighth day, from erosion of a pericardial vessel.

CASE III.

A bullet wound, with aperture of entry in the right postero-lateral part of the chest at the level of the sixth rib, had been received a few hours previously; the aperture of exit was on the left side anteriorly, at the same level and external to the nipple line. There was slight haemothorax on both sides, with marked left pneumothorax. Cardiac dullness was somewhat increased to the right; loud friction sounds were audible over the sternum. There was marked cyanosis, with rapid pulse and respiration. The abdomen was distended and slightly tender. The diagnosis made was perforated wound of the chest and abdomen, wounds of both pleurae, pericardium, and peritoneum, wounds of heart, lungs, and liver.

Operation.

A costo-xiphoid incision was made, commencing at the left costal margin, and carried upwards for four fingerbreadths. The peritoneum was opened, and a bleeding wound of the convexity of the liver was plugged. The sternum was then divided transversely, and the pericardium was freed from the pleura and opened. It contained fluid blood, and there was a deep transverse wound of the apex of the heart, not involving the ventricular cavity; the pericardium was perforated in two places. The wound in the heart was closed with two sutures, the perforations in the pleura and pericardium sutured without insertion of a drainage tube, which the experience of the previous case had shown to be disadvantageous, and the peritoneal incision closed, a gauze drain being brought out to the external wound. Owing to movements of the patient on recovering from the anaesthetic, recent adhesions in the left pleura gave way, producing an open pneumothorax. This necessitated removal of part of the comminuted fourth rib and fixation of the lower border of the lung. The case appeared to progress favourably until the twelfth day after the operation, when an increase in the area of cardiac dullness was noticed. On the twenty-fourth day a sharp rise of temperature occurred, and dilatation of the track into the pericardium revealed a localized abscess, which was then effectively drained. On the twenty-

seventh day the upper part of the abdomen was tense and tender, and death occurred twenty-four hours later.

Necropsy.

Recent general peritonitis by extension from a subphrenic abscess, which appeared to have originated from a stitch abscess in the deeper part of the abdominal incision. The pericardium was completely adherent anteriorly and at its upper part, and the small abscess cavity at its lower part showed no retention of pus. The wound in the ventricular wall had healed completely.

Professor Rehn considered that the patient would have been saved but for the abdominal complication, and that the stitch abscess was possibly due to his having used coarse silk instead of catgut for the sutures. He refers to the case published by Sauerbruch:

The patient received a grenade wound over the right half of the sternum at about its middle. The fourth costal cartilage, which was comminuted, was removed with a portion of the sternum. Haemorrhage had occurred into the mediastinum and a wound was found in the pericardium, from which blood exuded. On opening the pericardium a penetrating wound of the right ventricle was disclosed, from which blood spurted at each systole; the wound was sutured. Death occurred five days later from suppurative pericarditis. The *post-mortem* examination showed that the projectile had perforated the wall of the right ventricle and entered the wall again from within, becoming lodged in the muscle substance.

Oberstabsarzt Professor Thöle has described² a case in which he removed a bullet from the heart.

The patient had received a wound in the abdomen, and at the dressing station vomited a quantity of mucus once. On admission into the Feldlazarett the next day he was suffering from pains in the left side of the chest and beneath the costal margin, but there was no palpitation. A year later the man was admitted into a Kriegslazarett complaining of a feeling of pressure and painful tension in the left side of the chest, especially after exertion or deep breathing, but otherwise he appeared to be in good health. There was a scar 8 mm. in length, 7 cm. above and to the left of the umbilicus. Physical examination of the chest and abdomen revealed no abnormality. The pulse was regular, 76; no palpitation had at any time been felt. The x rays revealed a bullet at the lower part of the heart. The shadow was most distinct during the pause after deep inspiration, less so after complete expiration. The bullet lay transversely, with its point directed to the right, and moved synchronously with the ventricular systole and with the vertical movements of the diaphragm in deep breathing. It was situated nearer the anterior than the posterior wall of the thorax, and exactly in the angle where the shadow of the heart joined that of the diaphragm. It was concluded, therefore, that the bullet was not free in the pericardial sac, but was embedded in the wall of the right ventricle or in the connective tissue between pericardium and diaphragm.

Operation.

An incision was made, under local anaesthesia, from the middle of the sternum over the sixth rib cartilage to the sixth rib. The cartilage was then excised, the triangularis sterni muscle divided vertically close to the sternum and the internal mammary artery ligatured. While reflecting the muscle the left pleura was torn, and a clamp applied. This incision giving inadequate room, the fifth and seventh rib cartilages were excised, the rent in the pleura becoming increased to 7 cm., without, however, producing any serious symptoms. At this stage chloroform was administered, and, with the aid of the oxygen pressure apparatus, the wound in the pleura closed. A vertical incision was then made into the pericardium, which contained a considerable quantity of slightly turbid fluid. On palpation the apex of the heart, a little to the right of the interventricular septum, felt somewhat hard, but it was impossible to decide whether this was not due merely to systolic contraction. No scar was seen either on the visceral or parietal pericardium, nor were any adhesions present. Bimanual palpation, through an incision carried vertically downwards through the abdominal wall and diaphragm for 7 cm., gave negative results. Two pieces of catgut were then passed through the apex of the heart, and the organ drawn forwards. The apex of the right ventricle was explored with a needle, and the presence of the bullet immediately detected. A third piece of catgut having been passed through the hinder wall of the right ventricle, the heart was drawn forwards, a vertical incision 3 cm. long was made in the posterior wall, and the bullet removed. Bleeding was slight, and the incision was closed with three catgut sutures.

On the third day after the operation signs of pleurisy and pericarditis developed, and the patient died on the fourteenth day.

Professor Thöle attributes the suppuration to infection of the wound from the bullet, but no pus was visible around the bullet, and a bacteriological examination could not be made.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed in Action.

SURGEON K. M. DYOTT, R.N.

Surgeon Kenneth Mitchell Dyott, R.N., was reported as killed, in the casualty list published on December 20th. He took the L.M.S.S.A. in 1915, and joined the navy soon after.

Wounded.

Surgeon Probationer H. Gordon, R.N.V.R.

ARMY.

Died on Service.

CAPTAIN L. G. CROSSMAN, R.A.M.C.

Captain Lionel Gordon Crossman, R.A.M.C., died in hospital from double pleurisy and pneumonia. He was the younger son of Councillor John Crossman of Penllwyn Park, Carmarthen. He received his education at University College, Cardiff, and St. Bartholomew's Hospital, graduated B.Sc. Wales in 1910 and M.B., B.S.Lond. in 1913, and took the diplomas of M.R.C.S., L.R.C.P.Lond. in 1912. He had held the posts of senior house-physician at St. Bartholomew's Hospital, clinical assistant at the Hospital for Sick Children, Great Ormond Street, and resident medical officer at the Royal Hospital for Diseases of the Chest, City Road. Early in the war he joined the staff of the 1st London General Hospital, and went out with the Expeditionary Force to the East, where he had been for about eighteen months.

Wounded.

Lieut.-Colonel D. B. Cogan, M.C., R.A.M.C.(T.F.).
Major P. A. Maplestone, D.S.O., Australian A.M.C.
Captain A. C. Ainsley, R.A.M.C. (temporary).
Captain G. Allison, R.A.M.C. (temporary).
Captain A. Checchi, Australian A.M.C.
Captain J. V. Cope, R.A.M.C. (temporary).
Captain A. E. Delgado, R.A.M.C. (temporary).
Captain O. T. Evans, R.A.M.C. (temporary).
Captain D. J. Foley, R.A.M.C. (temporary).
Captain E. A. T. Green, R.A.M.C. (temporary).
Captain R. J. Lane, M.C., R.A.M.C. (temporary).
Captain W. C. McArdle, R.A.M.C. (temporary).
Captain P. W. McKeay, R.A.M.C. (temporary).
Captain J. Manuel, R.A.M.C. (temporary).
Captain O. Matthews, Australian A.M.C.
Captain J. F. W. Meenan, R.A.M.C.(S.R.).
Captain P. J. O'Shea, Australian A.M.C.
Captain W. S. Pickup, R.A.M.C. (temporary).
Captain J. R. Tibbles, R.A.M.C. (temporary).
Captain T. A. Townsend, R.A.M.C. (temporary).
Lieutenant B. Knowles, R.A.M.C.(S.R.).
Lieutenant E. C. Owens, R.A.M.C. (temporary).

Missing.

Captain J. Davidson, R.A.M.C. (temporary).
Captain H. S. Fairfax, R.A.M.C. (temporary).
Captain F. W. Fawcett, R.A.M.C. (temporary).
Captain J. Ferguson, R.A.M.C. (temporary).
Captain H. B. Guiding, R.A.M.C.(S.R.).
Captain F. B. Ryan, R.A.M.C. (temporary).
Captain F. M. Walker, M.C., R.A.M.C. (temporary).
Captain C. R. Wills, R.A.M.C. (temporary).
Lieutenant A. S. Gaziwal, I.M.S.

DEATHS AMONG SONS OF MEDICAL MEN.

Alexander, Alan Mansell, Second Lieutenant Scottish Rifles (Cameronians), second son of Dr. S. P. Alexander of Southsea, killed December 8th, aged 21. He got his commission in the fifth Territorial battalion of his regiment on September 26th, 1914, and had been on service abroad for the past fifteen months.

Gough, George Harry Waldron, Second Lieutenant Cheshire Regiment, eldest son of Dr. Harry Edward Gough, M.O.H. Northwich, killed December 15th, aged 23. He got his commission in August, 1915.

Peattie, David, Gunner Tank Corps, only son of the late David Peattie, surgeon dentist, Edinburgh, killed November 23rd.

Stewart, Vernon Radcliffe, Second Lieutenant Army Service Corps, attached Royal Flying Corps, accidentally killed on December 5th, aged 23. He was the elder surviving son of Dr. J. B. Stewart, Haslingden, and was educated at Giggleswick School, where he was a member of the O.T.C. and captain of the Rugby fifteen and cricket eleven. When war broke out he

was at St. Mary's Hospital, and had just passed the first part of the second M.B.Lond. He was given a commission in the A.S.C. in October, 1914, was promoted to lieutenant in March, 1915, and was at the first landing in Gallipoli. For his services there he was given a commission in the regular army. He transferred to the R.F.C. in September, 1916, and went to France, but was invalided to England with dysentery. On his recovery he was passed for home service, and at the time of his death was instructing in flying.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

England and Wales.

UNIVERSITY COLLEGE OF SOUTH WALES.

At a meeting of the Council of the University College of South Wales and Monmouthshire last week the Chairman, Lord Pontypridd, announced that Miss Talbot, of Margam Abbey, had given £30,000 to found a chair of preventive medicine in the college. A resolution of thanks to Miss Talbot for this munificent gift, which would provide a salary of £1,500 a year, was adopted. The resolution set out that in this way an urgent need could be met, inasmuch as the college would be able to appoint a professor with full expert knowledge and wide experience to control and conduct the teaching, research, and public health work of the Institute of Public Health and Preventive Medicine about to be established. The resolution went on to undertake to appoint as the first occupant of the chair the person selected for the office by a board constituted for the purpose by Sir William Osler. It is hoped that this example may be followed by others, so that the Welsh Medical School may be fully equipped and endowed in all departments.

DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES
IN LONDON.

At the meeting of the London County Council on December 18th the Public Health Committee recommended that the experimental scheme for the diagnosis and treatment of venereal diseases formulated a year ago should be continued, with certain modifications, for 1918. Six neighbouring counties and three extra-London boroughs share in the facilities afforded by the scheduled London hospitals, but it has been found that the proportion of London cases dealt with, instead of being 60 per cent., as originally estimated, is about 80 per cent. The total number of cases from all the areas up to September 30th was 11,976, and it is expected that 16,000 persons will have received treatment during the first full year. The scheme is reported by the medical officers and hospital committees concerned to have worked very satisfactorily, and no material revision is necessary for 1918, but it is proposed to reconsider the whole scheme, including the system of payments to hospitals, before the end of next year. The King Edward VII Memorial Institute, Lewisham; the Metropolitan Hospital, Kingsland Road; and the Hospital for Diseases of the Skin, Blackfriars, are to be added to the scheduled institutions. In response to representations that hostels should be established for young women suffering from these diseases, the Council agreed to make grants amounting to £260 in all to the Royal Free Hospital, the Women's After-care Hospital, Clapham, and the Woolwich Medical Home of the Southwark Diocesan Association, which are to provide thirty-two beds between them. The basis of the Council's payment will be at the rate of 30s. a week for, roughly, two weeks, representing the period of infectivity, though the stay of the patients in the institutions may extend some while longer. The estimate made last year of £27,500 for salvarsan and its substitutes has proved to be very much in excess of requirements, and it is probable that not more than £1,000 has been spent under this head during the year. The demand, however, is progressive, and £5,000 has been included for this purpose in the estimate for 1918. That estimate amounts in all, for the County of London alone, to £38,560, of which sum £32,000 represents block grants to hospitals for treatment and pathological examinations. Three-fourths of this expenditure is recoverable from the national exchequer. The

recommendation that the scheme be continued for another year was adopted unanimously after a brief discussion, in which the Rev. Scott Lidgett and other members spoke warmly in support of the hostels proposal.

REMUNERATION OF MIDWIVES.

It was reported to the London County Council on December 18th that the Midwives Act and General Purposes Committees, after considering various memorandums on the subject of a State aided midwifery service and the general conditions of midwifery practice, had both come to the conclusion that no sufficient reasons had been advanced for the adoption of a State-aided scheme. At the same time they agreed that there was considerable evidence that midwives were inadequately remunerated, and thought that this question should engage the serious attention of the authorities concerned, but that it should be dealt with as part of a general scheme for the health of London, such as could be anticipated in connexion with the proposals for the formation of a Ministry of Health. Mr. A. L. Leon moved an amendment proposing that the Government should guarantee to midwives a fee of not less than 20s. a case, leaving it to the Government to arrange for the recovery of part or the whole of the amount. He said that the shortage of midwives was getting more acute every year. Mrs. Wilton Phipps considered that the question could not be detached from the general health services, and, on being put to the vote, Mr. Leon's amendment was lost and the committees' recommendation adopted.

MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

It was reported to the London County Council at its meeting on November 27th that the arrangements made for the medical and dental treatment of school children for the year beginning April 1st next included provision for 28,880 eye cases, 13,140 ear, nose, and throat cases, 2,114 ringworm cases, and 30,410 cases of minor ailments, a slight increase in each category upon the figure of the previous year. The dental provision is to be enlarged to admit of the treatment of 90,000 children annually at 44 centres; the arrangements at present provide for 67,760 children at 38 centres. The cost of the proposals will be £43,823, of which sum more than half is on account of dental treatment. Forty full-time district nurses are engaged or proposed to be engaged in the treatment of minor ailments. A further report stated a day class in remedial exercises for stammering children, who number 1,500 in the London schools, is being started; a similar experiment, which has been proceeding for some time at one of the evening institutes, has had excellent results.

THE ENEMIES OF CHILD LIFE.

In the Priestley lecture on "The enemies of child life, with special reference to home conditions," delivered before the National Health Society on November 21st, Sir Arthur Newsholme dealt with his subject under two chief headings—(1) adverse influences prior to birth or within the first month of life; and (2) those arising up to the age of five years. He first challenged the common statement as to equality of health of infants at birth. This was proved to be erroneous by the varying prevalence of congenital diseases; by the different incidence of still-births in different parts of the country, varying as they did between 3 and 8 per 100 live births; and by the unequal death-rate in the first month and first week after birth, at which age prenatal causes of death and causes in connexion with confinement were chiefly in operation. The importance of maternal malnutrition as affecting the unborn infant was great, not only in relation to the health of the infant at birth, but still more as influencing the ability of the mother to suckle. The statement that the death-rate of infants under one month is in the main irreducible, and is fairly constant throughout the country, was next shown to be erroneous. Remedial measures for the maternal and infantile causes of excessive sickness and mortality at this period of life were then discussed, including maternity benefit under the Insurance Act and the rapidly increasing work under the schemes of the Local Government Board. Dealing with the second half of his subject, the lecturer showed that more than half the total deaths in the first five years after

birth are due to infections, including catarrhal diseases of the respiratory tract; the larger part of these deaths, and of the associated much greater bulk of sickness, being preventable. The greater child mortality in towns, as compared with the country, was chiefly caused by the excess of these infections. The lecturer here rebutted the statement that excessive mortality was inevitable in town life and due to any general atmospheric condition affecting crowded centres of population. The problem of child mortality formed a complex social problem, many factors bearing a part. The chief difference between urban and rural life was in housing conditions. Greater opportunities for human organic poisoning and infection were inevitable in towns so long as it remained true that more than six times as many families lived in one-room tenements as in rural districts, and that overcrowding in such small tenements was much greater than in rural tenements of corresponding size. New schemes for housing, although they would give invaluable help, would leave the conditions in the central parts of towns unsatisfactory for many years to come, unless at the same time active additional measures were taken. The chief enemies of the child were within the home itself. Personal faults in the parent, notably intemperance, played an important part in the conditions adverse to child welfare. Again, the industrial employment of women was an obstacle to normal family life, and the problem was how to safeguard the child in its mother's absence under modern conditions. A healthy home could not be secured unless municipal authorities co-operated in many directions. But though urbanization was attended by many drawbacks it presented also certain advantages. The ideal city should be regarded as the larger home in which every family was a co-partner, the need for such continuity between the home and the city being specially marked in time of sickness, when the hospital was the best home for sickness in a large and increasing proportion of the total sickness of the community. In no department was the extension of the hospital home more needed than for parturient women, and for infants under special conditions. Sir Arthur Newsholme forecasted that ere long we should see still more rapid extensions in these directions. Although much had been done in various ways, much more remained to be effected. This would cost money, but health was always cheaper than disease, and within limits the community could have as much health as it was prepared to pay for.

Ireland.

REMUNERATION OF MEDICAL OFFICERS.

We learn from the *Cork Examiner* that the Board of Guardians of Newcastle West, co. Limerick, recently resolved to make a permanent increase of £40 a year in the salaries of the medical officers of the union. At a meeting on December 13th this resolution was rescinded by 25 votes to 18. A proposal was made to grant a war bonus of £30 a year, leaving over the matter of a permanent increase to be decided after the election of the new board. The chairman was about to put this proposal, when he received a letter from the six medical officers resigning their position, and giving a month's notice. The clerk was instructed to advertise for medical officers to fill the vacancies at the next meeting. A correspondent commenting on this suggests that encroachments under the Insurance system should be dealt with "in a similar virile, manly, and instantaneous manner."

PAUPERISM IN IRELAND.

Pauperism in Ireland in November was 1 per 10,000 of the population above the previous month. The increase in the month was mainly in the Cork, Waterford, and Limerick districts. Compared with November, 1916, pauperism in the Dublin district showed an increase of 13 per 10,000, but a decrease in the rest of Ireland, the greatest rate of increase being 9 per 10,000 in Cork, Waterford, and Limerick districts. Pauperism in Ireland differs from pauperism in England and Scotland in respect of outdoor relief. The cases of outdoor relief in England are 23 per cent. more than the cases of indoor relief, and

in Scotland are five times as numerous, whilst the number of cases in both classes of relief in Ireland are nearly equal, the first being equivalent to 91 and the latter to 92 per 10,000 of the population. Pauperism in Scotland is 158 and in England 113 per 10,000 for both forms of relief combined. The highest rate of pauperism in Ireland was in the cities of Cork, Waterford, and Limerick, where it reached a total of 263 per 10,000, but in Dublin it was as high as 260 per 10,000. In Galway it was less than half the rate in the southern and eastern districts, being only 120, and in Belfast it was 70 per 10,000. Pauperism in the London County Council area amounted to 158 per 10,000, but in the central district it reached the enormous rate of 312, and in the east was 211. The employment at munitions and war work has diminished pauperism in England, where it was 12 per 10,000 less than in November, 1916.

Sydney.

THE UNIVERSITY MEDICAL CURRICULUM.

At a recent meeting of the University Senate, on the recommendation of the Faculty of Medicine, and in order that the present fourth year medical students may be afforded an opportunity of enlisting for war service if necessary after graduation, it was resolved that the curriculum for the present fourth year medical students be slightly compressed; and that they be permitted to present themselves for the final degree examination in December, 1919, instead of March, 1920.

THE RED CROSS SOCIETY AND THE RANDWICK MILITARY HOSPITAL.

An interesting account was given to a recent meeting of the Red Cross Society of the efficient and sympathetic Red Cross organization in connexion with No. 4 Australian General Hospital at Randwick carried on for the past two years by an honorary staff of business and professional men. The doctors and nurses at the hospital gave the Red Cross representatives assistance in many ways, while the girls at the Voluntary Aid Detachments lent their aid in serving refreshments for the out-patients as well as the in-patients. The main objects of the Red Cross Society at the hospital were to visit all the wards, so as to ascertain the needs of the patients, and to explain to the men what this society was able to do for them. The operations of the Red Cross Society included a gymnasium for massage treatment, a recreation hall, a library, arts and crafts lessons for teaching leather work, carving, basket work, and cushion making. Book-keeping and photography were also taught. In the way of amusements, concerts, picture shows, and gramophones were provided. There was a room for mending clothes, and conveniences for letter writing. Whenever motor cars were lent the men were taken for drives.

LONGEVITY IN AUSTRALIA.

Mr. G. H. Knibbs, the Commonwealth statistician, has obtained some interesting results from an analysis of the age data for the censuses of 1881, 1891, 1901, and 1911. At the census of 1881 children under the age of 15 represented 38.9 per cent. of the total population of the Commonwealth, the proportion for subsequent censuses being 36.9 in 1891, 35.1 in 1901, and 31.6 in 1911. At the census of 1881 persons aged 70 and upwards represented 1.3 per cent. of the population, 1.5 per cent. in 1891, 2.1 per cent. in 1901, and 2.6 per cent. in 1911. These figures afforded evidence of the increasing age of the population of Australia. The influence of the South African war in 1901 on the age statistics was shown by the fact that while males between the ages of 20 and 30 represented 20.5 per cent. of the total male population in 1891, and 18.7 per cent. in 1911, they represented only 17.3 per cent. in 1901. The high proportion at this age in 1891 is attributed by Mr. Knibbs to the large amount of immigration which took place during the preceding ten years.

THE Spanish-speaking doctors practising in New York have founded an association named La Sociedad Medica Hispano-Americana. The secretaries are Drs. Manuel Uribe y Troncoso and Anibal Zelaya. At each meeting the chair will be taken by some member chosen for the occasion.

Correspondence.

THE MINISTRY OF NATIONAL SERVICE AND THE ARMY.

SIR,—The appeal to the nation in Mr. Lloyd George's speech on December 14th will be of little avail unless it evokes a whole-hearted response from the majority of the members of the community; and the response of individuals can only be made effective through bodies which are representative of sections of the people. One such section is the medical profession; and it seems to me that there are certain bodies pre-eminently concerned with medical interests whose members should ask themselves, "Are we doing all that is in our power to help in winning the war?" These bodies are the Army Medical Department, the Medical Department of the Ministry of National Service, and the statutory professional committees.

How many of the responsible officials of these bodies, after reading the Premier's speech, have thought of its bearing on themselves and their work? How many of the innumerable committees now in existence have paused in their floods of eloquence to ask, "Is all well with us?" Is it perhaps true that heads of departments, members of committees, and secretaries resent new ideas because they involve thought and work; that they drift into routine; and that they swathe themselves with tape which is red, even though it may not be of strict Government hue?

All the bodies mentioned have done and are doing excellent work. But at the risk of being thought censorious, I suggest that human nature is prone to pride itself on what it has done and to forget how much more might be done by using greater effort. Human nature is liable also to suffer from jealousy and suspicion, so that very often the best man is not used for the work which has to be done. Prerogatives are carefully guarded, shortcomings not recognized, interference resented. As a result co-operation is refused, and in the end committees of inquiry are set up which are wasteful both of time and money.

The difficulties of the Army Medical Department have been great. In the face of these difficulties it has rendered immense services, preventive and curative, to the armies, but it has not always been receptive to new ideas. It has not availed itself to the full of the enormous body of highly qualified men who are now serving in the R.A.M.C. It is still jealous of the civilian. It does not make use of the most competent business men in administrative matters. It has not accepted full, open, and unselfish co-operation with medical bodies which could help it in its difficulties.

The statutory professional committees have done a great work in regulating the flow of medical officers into the army, but they have grown old enough to be slow in receptiveness, to be content with routine, to be afraid of action, and to be jealous of prerogatives. They have a tendency to become unwieldy in the number of their members, and to rely on committee meetings instead of hard office work. Moreover, each committee lacks a whole-time secretary, who is so necessary in view of the far-reaching importance of the work.

The Medical Department of the Ministry of National Service is less open to criticism because it is so young. It is displaying wisdom in the confidence it places in voluntary bodies representative of the medical profession and in the use it is making of them. The chief dangers lie in the magnitude of the task that has been thrust upon the department and in the possibility of a hostile attitude on the part of other Government departments as the work of the National Service Ministry increases. At present the Army Medical Department is rejoicing in the idea that a buffer has been established between itself and a critical public. But the buffer has also the function of standing between the public and an Army Medical Department which has not always dealt sympathetically with the civilian side, so that the path of the National Service Ministry is not likely to be smooth.

So far as medical service is concerned, there would have been no need for intervention by the Ministry of National Service if the War Office had treated the statutory professional committees in a more liberal manner and if the committees had thrown themselves more strenuously into the work. But, as the Ministry of National Service

is now a partner in the concern, it is to be hoped that all differences will be forgotten, and that the military and civil sides linked up by the Ministry will work harmoniously towards the same end.—I am, etc.,

December 17th.

X.

PENETRATING GUNSHOT WOUNDS OF THE CHEST AND THEIR TREATMENT.

SIR,—In the interesting remarks on penetrating wounds of the chest and their treatment by Major Gask and Captain Wilkinson, published in your issue of December 15th, there is one statement on which I should like to comment. The authors say that "when the haemothorax is large enough to produce symptoms by its size it is aspirated; otherwise the chest is only needled if the condition of the patient suggests that a haemothorax is becoming infected. . . ."

The after-history of many cases of haemothorax seen in this country shows clearly that such conservative treatment is not satisfactory. Delayed absorption of the blood is very far from being the exception, and when these cases are aspirated some weeks after the injury, it is often impossible to remove more than part of the blood. The recovery of the patient is undoubtedly more complete if all cases of fluid haemothorax are aspirated by oxygen replacement at the earliest possible moment.

No mention is made of the treatment of sterile haemothorax by thoracotomy—a method which I advocated at the meeting of the Medical Society in January, 1916. There are two groups of cases in which it is indicated: (1) When absorption has been delayed as mentioned above. The rapidity of the improvement and recovery of the patient after this treatment is most striking. (2) When the blood has clotted soon after the injury. In such cases it is generally found that the coagulum has formed round a metal fragment or pieces of clothing which are infected, or round penetrating fragments of rib with laceration of the pleura. The early removal of the whole clot before the organisms have spread through it, and the closure of the thorax, will often prevent the development of an empyema.—I am, etc.,

London, W., Dec. 17th.

H. MORRISTON DAVIES.

TREATMENT OF DISCHARGED TUBERCULOUS SOLDIERS.

SIR,—In the report of the Lancashire County Council on the sanatorium treatment of tuberculosis, published in your issue of December 1st, the medical officer states that "the treatment of discharged soldiers and sailors suffering from tuberculosis has not been attended with great success owing to the difficulty of enforcing discipline apart from the military control." I wish to confirm that statement.

After having seen the result of treatment in a large number of cases (both in a civil institution and in a military hospital) I am convinced that better results are obtained when soldiers are treated under military control; and I have pointed this out to the M.O.H. of the county.—I am, etc.,

December 8th.

R.M.O.

HOW IS THE EARLY DIAGNOSIS OF PULMONARY TUBERCULOSIS TO BE MADE?

SIR,—With reference to the great importance of the early diagnosis of pulmonary tuberculosis, I should like to call attention to the limitations of the stethoscope as an aid to early diagnosis.

Laryngologists see a number of cases of early tuberculosis because tuberculous patients are peculiarly susceptible to chronic catarrhal affections of the nose, pharynx, and larynx. For example, frequent and prolonged attacks of laryngitis, with asymmetrical or patchy redness of the vocal cords, or perhaps slight thickening of the posterior commissure of the larynx, always raises the suspicion of tuberculosis, but on inquiry the patient states, "My doctor examined my chest and said it was all right"; or the case is sent to a physician for examination of the chest, with the result that the case is returned labelled, "No physical signs." Subsequent thorough examination of the sputum reveals the presence of the tubercle bacillus, and the

patient's chart shows an evening temperature and loss of weight.

The above type of case is so common that the keenest stethoscope is distrusted, and a negative stethoscopic examination is misleading and worse than useless. When physical signs are detected by the stethoscope, it means that the disease is comparatively advanced. The presence of chronic catarrh of the nose, pharynx, or larynx in a young adult for which no adequate local or general cause can be found, and more particularly if the victim is "run down," should raise the suspicion of pulmonary tuberculosis. In these cases a careful examination of the sputum, temperature, and weight is much more likely to reveal the true condition of the patient than many stethoscopic examinations of the chest by the most experienced exponent.—I am, etc.,

London, W., Dec. 3rd.

EDWARD D. D. DAVIS.

SIR,—Whilst agreeing with much that Dr. Lachlan Grant says in his letter in your issue of December 8th, I should like to point out that haemoptysis occurred as an initial symptom in 18.6 per cent. of men patients in which this matter was inquired into, who at the time of inquiry were suffering from well-marked pulmonary tuberculosis; and pleurisy was found to be antecedent in 18.2 per cent., making nearly 37 per cent. in all, of cases which might have been easily diagnosed. In the case of those suffering from haemoptysis, an average of almost three years had elapsed before they were first treated seriously, and in the case of the pleurisy an average of four years and four months had elapsed before serious treatment was undertaken.

In cases of doubt, where symptoms of fever are present, such as night sweats, the most important thing for the family medical adviser to do is to put the patient to bed, and, if there is a dry cough, to check it appropriately, and not to allow the patient to go about, for, although under the latter regimen he may in time spit up tubercle bacilli, this should not be the aim of treatment. Rest is the sheet anchor in our treatment of early cases. Night sweats—a common symptom in early cases—is due to walking about and exercising diseased foci in the lungs which produces toxæmia, and so fever and then night sweats.—I am, etc.,

EDWARD E. PREST.

Ayrshire Sanatorium, New Cumnock, Dec. 10th.

THE RURAL PANEL PRACTITIONER.

SIR,—When I sent my subscription to the British Medical Association at the beginning of this year I also intimated my resignation, to take effect at the end of the year. My chief reason for resigning, after a membership of over twenty years, was a conviction that the interests of the rural practitioners were more or less ignored by the leaders of the Association. At any rate, who can deny that, since the coming of the Insurance Act, the rural doctor has never had fair play compared with the industrial area practitioner? And at the present time his position is worse than ever, owing mainly to the increased cost of travelling and drugs. These two points do not affect the doctors in towns and colliery districts, but they are the most glaring and urgent grievances under the Act, and should be remedied first. Let the Insurance Acts Committee obtain a more reasonable allowance for drugs and mileage, and then press, if they like, for a ten shilling capitation grant. The "big panel" doctors are far better off than they were before the Act in spite of the increased cost of living, and to talk of wholesale resignations is mere moonshine.

I shall be reminded that we have a subcommittee of six appointed to look after rural interests, but we have not yet heard that they have achieved much, and, in any case, some of its members are men practising in towns of 12,000 or 13,000 inhabitants, with panels that are certainly not predominantly rural.

However, of late the Insurance Acts Committee appears to recognize the fact that there are such people as rural practitioners, and that the conditions of working the Act in rural districts are not quite the same as the conditions in populous areas; and, of course, we could not expect action until these facts were recognized. Because this gives a glimmering of hope, and because I find the JOURNAL

useful (mostly for its advertisements) I have decided to withdraw my resignation.

The miserable have no other medicine
But only hope.

—I am, etc.,

December 13th.

TRULY RURAL.

RURAL PRACTICE.

SIR,—In the obituary notices of a medical man I read an appreciation by a colleague, which began thus: "Though only a country practitioner . . ." suggesting that rural practice is always chosen from inability to compete with our town friends. It is strange that the country doctor is so often regarded as of an inferior type. My experience is quite the contrary. Having served at sea and in large practices, I can say that none have taught me more than my country colleagues, and nowhere is self-reliance implanted so firmly.

Take, for example, a difficult midwifery case miles from any help, with no friendly practitioner round the corner to give a hand. Here the responsibility has to be faced alone. Perhaps it will not be amiss to quote my midwifery record during the past year: There were thirty-five cases, and of these eleven were normal. Among the twenty-four complicated cases of labour twelve needed forceps; in one I had no one to give chloroform. There was one case of *ante-partum* eclampsia; three genuine cases of painless labour, in each of which turning was performed; one case of impacted breech; three occipito-posterior cases; one shoulder case with cord presenting; one peculiar case of cardiac dropsy in which the size of the abdomen remained practically unchanged after delivery; one case of persistent fainting attacks; and, finally, a case of difficult delivery, the infant having an enormous syringomyelocoele. In two of the cases I had the kind help of Dr. Welsford of Tiverton. Town colleagues say we should not attempt these difficult cases alone, but the fact is we must, "though only country practitioners." I often think of the couplet:

Luckless is he whom hard Fates urge on
To practise as a country surgeon.

The much advertised inducements of fishing, shooting, golf, etc., seldom, indeed, come our way. Seldom even are we able to attend our local British Medical Association meetings. Here may I say that what strikes me about recent discussions in the JOURNAL is the lack of unity among medical men. I am sure our position would be far better if we did but pull firmly together, headed by our British Medical Association representatives.

So long as this inability to unite continues we shall remain public slaves. Take the infectious notification fee. My last diphtheria case cost me in stamps much more than the miserable shilling. Such is our reward for safeguarding the public with risk to ourselves and our families. Lastly, as to panel work, I may quote one of many such cases. I recently paid twenty visits to a man some six miles or more from my home—one visit at midnight—over the roughest lanes, and this for 11s. a year. With petrol 4s. a gallon, and drugs so expensive, how can it be done?

Need I say that the object of this letter is not to eulogize myself, but to point out a few of the trials and troubles of the country doctor.—I am, etc.,

DAVID H. VICKERY,

Cheriton Fitzpaine, Nov. 24th.

Surgeon R.N. (invalided).

Obituary.

THE death occurred, on December 7th, of Dr. FREDERICK EDWARD WALKER, of Uxbridge, at the early age of 43 years. After studying medicine at Guy's Hospital he qualified M.R.C.S., L.R.C.P. in 1889, and three years later he took the M.B., B.S. degrees of the University of London. He served as civil surgeon during the South African war, and received the Queen's medal with three clasps. He afterwards settled in practice at Uxbridge. In 1912 he became medical officer to the Uxbridge Rural District Council, and during the war acted as medical officer to the urban district and to the Uxbridge Union. He was a member of the Urban District Council, and captain of the local fire brigade. The very large number of organizations represented at his funeral showed the respect in which he was held. He leaves a widow and two young children.

Dr. THOMAS FISHER, of Great Eccleston, who died on December 1st, was the son of the late Mr. John Fisher of St. Michaels, and was educated at Alston College and St. Thomas's Hospital. After taking the diplomas of M.R.C.S. Eng., and L.S.A. in 1876, he settled in practice at Great Eccleston. He was a J.P. for the county of Lancaster, a member of the Blackpool Division of the British Medical Association, M.O.H. for the Garstang Rural District, and medical officer to the Joint Small-pox Hospital, Elswick. In 1916, owing to the great calls on the medical profession caused through the war, Dr. Fisher accepted the appointment of acting medical superintendent of the Lancashire County Council Sanatorium at Elswick. He leaves three sons and one daughter, two of the former being members of the medical profession.

BRIGADE SURGEON WILLIAM NOLAN, Bombay Medical Service (retired), died suddenly at Wallington, Surrey, on December 11th, aged 75. He was educated at Trinity College, Dublin, where he graduated B.A. in 1864, M.B. in 1865, M.D. in 1868, and M.A. in 1883; he took the diploma of M.R.C.S. in 1866. He entered the I.M.S. as assistant surgeon on April 1st, 1867, became surgeon on July 1st, 1873, surgeon-major on April 1st, 1879, and retired with a step of honorary rank on September 24th, 1887. He served in the Abyssinian war in 1868 and received the medal.

ASSISTANT SURGEON THOMAS PARKER SMITH, formerly of the Army Medical Department, died at Reigate on December 4th, aged 81. He was educated at Owens College, Manchester, and graduated M.B. Lond. in 1858 and took the dipl. mas of M.R.C.S. and L.S.A. in the same year. He entered the army as assistant surgeon on March 31st, 1862, but after six years' service, spent partly on the staff and partly in the Royal Munster Fusiliers, retired on half-pay on December 12th, 1868, nearly half a century ago. Before joining the army he had held the post of house-surgeon to the Staffordshire General Infirmary. He translated from the German, for the New Sydenham Society, several volumes, *German Clinical Lectures*, part of *Billroth's Surgery*, and Senator's *Albuminuria in Health and Disease*.

The Services.

HALF-PAY FOR SURGEON-GENERALS.

AN Army Order has been issued providing that a Surgeon-General of the Army Medical Service promoted to that rank after the date of the Order (December 20th) shall be placed on half-pay at the rate of £1 15s. a day after four years' service in that rank.

EXCHANGES.

M.O. attached Northern Command would like to exchange with M.O. attached London Command.—Address, No. 4349, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.2.

Medical officer serving in the Northern Command would like to exchange with one serving in the London Command.—Address, No. 4200, BRITISH MEDICAL JOURNAL Office, No. 429, Strand, W.C.2.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following candidates have been approved at the examination indicated:

THIRD M.B., B.C.—*Part I, Surgery and Midwifery*: I. de B. Daly, R. French, A. R. Hargreaves, C. E. Kindersley, J. G. Lawn, H. Morrison, F. P. Nicholas, A. G. Shurlock, E. B. Verney, C. H. Vernon.

UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examinations indicated:

FINAL M.B. and CH.B.—C. F. J. Carruthers, J. Charnley, J. C. T. Fiddes, M. C. Paterson, R. S. Paterson, Elizabeth C. Powell, *Forensic Medicine*: T. Colley, S. E. Critchley, F. L. Whincup.

THIRD M.B. and CH.B.—*General Pathology and Morbid Anatomy*: Nooman Abdoh, Elizabeth C. Davies, Kathleen Doyle, Georgiana M. Duthie, Olive M. Gimson, F. G. Hammett, A. Harris, S. Kelly, J. N. Luing, J. G. Nolan, Olga G. M. Payne, F. L. Pickett, Edme Ratner, W. Reikan, Annie G. Thompson, Doris M. R. Tompkins, Ruth A. Wilson. *Pharmacology and Therapeutics*: R. J. Allison, Mary E. Boullen, P. Fildes, A. Harris, A. E. H. Sadek, Ethel D. Willis, J. Yates. *Hygiene*: R. J. Allison, A. M. Cotes, L. B. A. Edleston, A. E. H. Sadek, Ethel D. Willis, J. Yates.

UNIVERSITY OF LONDON.

The following candidates have been approved at the examinations indicated:

M.D.—Branch I (Medicine): Dorothy Chick, H. J. O. Ewing (University Medal), Mary E. Joll, G. W. Lloyd. Branch V (State Medicine): P. Smith.
M.S. Branch I (Surgery): W. E. Tanner.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary Council was held on December 13th, when Colonel Charters Symonds, Vice-President, was in the chair.

Issue of Diplomas.

The diploma of Fellowship was granted to Mr. H. E. Griffiths, M.R.C.S., L.R.C.P., of St. Bartholomew's Hospital, who qualified at the recent examination.

Diplomas of the Licence in Dental Surgery were granted to twenty-two candidates found qualified.

Appointment of Representatives.

The following representatives of the College were appointed: Sir Berkeley Moynihan to the Court of Governors of the University of Birmingham, Mr. D'Arcy Power to the Court of Governors of the University of Bristol, Mr. W. G. Spencer to the Central Council for District Nursing in London.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

The following gentlemen, having passed the requisite examination, have been admitted Fellows: A. F. Cole, Subodhchandra Datta, S. Forsdike, J. Geoghegan, W. M. W. Shepherd, R. Tennent, N. J. Wigram.

The Liston Victoria Jubilee Prize of £100 has been awarded to Mr. D. P. D. Wilkie, F.R.C.S.E., for his valuable work and contributions with special reference to abdominal surgery.

Medical News.

THE King has conferred the Order of Mercy on Colonel R. J. Blackham, C.I.E., D.S.O., M.R.C.P.E., who is now serving as A.D.M.S. of a Division in Italy.

PROFESSOR F. DE QUERVAIN has been appointed to the chair of surgery in the University of Berne in succession to the late Professor Kocher.

OFFICERS of the United States Army Medical Service while stationed in Dublin or in its neighbourhood are invited by the Royal College of Physicians of Ireland to make use of its library.

THE American periodical *Pediatrics* has been incorporated with the New York *Medical Review of Reviews*, the editor, Dr. W. E. Fitch, having been called up for service in the army.

THE Cuban Red Cross is equipping a hospital unit with one hundred beds for active service on the Western front in France. It is staffed by Cuban doctors and nurses. A fund of £200,000 is being raised for the purpose by Cuban women. A national Red Cross day has been arranged for all parts of the Republic.

As the Viennese medical practitioners have to rely mainly on the electric trams for getting to their patients, and as the trams are often overfilled, it is proposed that the conductresses should be instructed to give practitioners establishing their identity a first claim to a seat.

SIR AUCKLAND CAMPBELL GEDDES, M.D., M.P., Minister of National Service, was sworn a member of the Privy Council on December 21st. As at present arranged, he will introduce the new amending Military Service Bill—the fourth of the series—on the reassembly of Parliament on January 14th. It is not probable that it will affect the medical situation in any way.

THE Department of the Seine intends to expend a sum of £40,000 on the establishment of tuberculosis dispensaries, which will be provided with nurses and health visitors of both sexes. The provision is made in accordance with a law which came into force in April, 1916.

THE annual congress of the Ophthalmological Society of the United Kingdom is to take place in London on May 2nd and two following days. Discussions will be held on the plastic surgery of the eyelids and on contagious diseases of the conjunctiva, and a number of demonstrations will be given. A museum, including a special exhibition of perimeters, is being arranged. Communications on this subject may be addressed to Dr. A. C. Hudson, 50, Queen Anne Street, London, W.1.

AT the seventh clinical Congress of Surgeons of North America, held in Chicago October 22nd to 26th, Surgeon-General Brinistad stated that whereas there were formerly 394 medical officers in the United States Navy there were now 828, the full authorized strength, and, in addition, over 700 in the naval reserve corps. The navy had twelve

hospital units organized under, and in conjunction with, the Red Cross, and five small naval stations. In the four naval hospital corps training schools there were sometimes a thousand men. Two ships were now being converted into hospital ships, and one now in course of construction would be from the keel up of a new type.

In response to medical representations, the Prussian Minister for the Interior has put the muzzling order again into force in greater Berlin. While it was in force very few people were bitten by rabid dogs, but in 1912, after its repeal, 26 cases occurred, and the average annual number of dog-bites notified by the police was about 100 a year.

By order of the Surgeon-General of the United States army an officers' school of oral and plastic surgery has been established for the training of a limited number of the medical reserve and dentists in the care of wounds of the face and jaws. The school is planned for the training and placing of a number of officers sufficient for the care of the face injuries among a million men in hospitals, and eventually a section of the staff will be established in every base and evacuation hospital. The first school has its headquarters at the Washington Medical School (St. Louis), which on the entry of the United States into the war offered to the Government the use of its new laboratories, hospitals, and clinics, and the services of its faculty. The instructors have been chosen chiefly from the faculties of Washington and St. Louis medical schools. The latter offers intensive work in anatomy, operative surgery, anaesthesia, and dentistry. The first course began on October 15th.

THE annual report of Livingstone College for the past year states that the reasons for the temporary discontinuance of the courses of study are, if possible, more urgent now than in August, 1915, when the college was transformed into an auxiliary military hospital. During the past twelve months over 99 per cent. of the beds had been fully occupied, and the admissions since the hospital was opened exceed 1,500. No attempt is made to forecast the programme of the college when it becomes once more a school for the training of missionaries in the elements of medicine, surgery, and hygiene, but the committee believe that, as a result of experiences during the war, a great impulse will be given to the work of Livingstone College.

IN the city of New York during 1915 there were about 15,000 cases of diphtheria with nearly 1,300 deaths, nearly 10,000 of scarlet fever with 291 deaths, over 38,000 of measles with 630 deaths, and only 174 and 95 cases respectively of cerebro-spinal meningitis and acute poliomyelitis. Three quarters of the patients with diphtheria and scarlet fever were treated in their own homes. A great deal of anti-tuberculosis work is done; 33,000 patients were under treatment at the various tuberculosis clinics during the year, under the charge of 67 special physicians and 41 volunteer physicians. As regards venereal disease, the department gives advice freely but undertakes no treatment at all; there are "Wassermann clinics" and a medical adviser, the former dealing with nearly 17,000 patients, the latter with 3,721. Deaths from rabies numbered 22 in the three preceding years; in 1915 only one occurred, though 279 patients were treated at the "Antirabic Clinics," and 103 rabid dogs (laboratory confirmation) were dealt with. There were 3,648 cases of dog-bite reported; 404 of these dogs were muzzled, 440 were on the leash, and 263 were both muzzled and leashed. The American S.P.C.A. collected and destroyed 35,537 dogs during 1915.

AFTER retelling in a singularly interesting manner the story of Burke and Hare, who in 1828 made a vocation of murdering the unprotected waifs and strays of Edinburgh to provide themselves with a livelihood and the dissecting rooms with subjects, Dr. C. W. Burr of Philadelphia discusses (*Annals of Medical History*, New York, 1917, i, 75-82) the psychology of murder. He first clears the ground by ruling out killing in self-defence, in a sudden access of passion, and by the insane; and this done, defines the murderer from the psychological point of view as the man who, without any temporary change in his usual psychical condition, can coldly contemplate and leisurely plan the killing of another for his own apparent benefit; such a one is psychologically a murderer, whether or not he ever kills, if, after planning the deed, he drinks to give himself the necessary courage, or if he hires another to carry out his plan. The one quality lacking in all sane murderers is the moral sense or the realization of a duty towards others who have an equal right to live; the murderer is colour-blind to morals, and never feels remorse or grief on account of his victim. The cause of this want of moral sense we no more know than we know what produces it; it is independent of intellect and environment. The murderer is born not made, and comes of a type apart and distinct from all other men.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are:

1. EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aditology*, *Westrand, London*; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, *Westrand, London*; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Mediscera*, *Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subject to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

QUERIES.

INCOME TAX.

C. S. has retired from practice, and has been doing duty as a regimental M.O., having been appointed in a civilian capacity. He points out that though his expenses have been similar to those incurred by military officers, he is taxed at the civilian rates instead of the special "service" rates.

"In the circumstances detailed by our correspondent he seems to be in an unfair position as compared with officers who do similar work, but, being commissioned to the R.A.M.C., obtain the special relief extended to army pay; but the legality of the rate of duty levied depends apparently on the nature of his employment, and if the terms of his engagement with the War Office are such as to constitute his remuneration "civilian" rather than "military" pay, we fear that he has no remedy.

LETTERS, NOTES, ETC.

WANTED—A MUSEUM OF QUACKERY.

DR. EDGAR F. CYRIL (London) writes to suggest that, pending any effort to obtain legislation which may be possible after the war, good might be done by the formation of a museum of quackery open to the general public. He suggests the exhibition, in addition to samples of patent medicines with their selling price and estimated cost of production, preparations of foods which, unaided by anything else, are said to be sufficient to support life and create unheard-of degrees of efficiency.

COWS AND TYPHOID FEVER.

F. L. O. writes that he has been informed by a combatant officer that it is accepted as a well known fact in India that if cows are allowed to drink contaminated water they are capable of transmitting typhoid bacilli through their milk. This opinion is probably erroneous; it rests possibly on some observations by Colonel Fred. Smith, who found agglutinins in the serum of cows. All attempts to cultivate typhoid bacilli from cow's milk proved negative. At the same time it is to be remembered that the udder is liable to faecal contamination, and it is possible that such contamination may occasionally contain typhoid bacilli from a human source, but the risk must be somewhat remote.

TREATMENT OF MALARIA.

DR. EDWARD YEATES, F.R.C.S.I., writes with reference to the note published on November 24th, p. 699: The treatment as set forth is, I believe, correct as far as the administration of quantities of quinine is concerned, but very necessary details are omitted.

1. In almost every case calomel should be administered first, in small or large quantities to suit the patient, otherwise the portal system is liable to become congested when the quinine gets busy on the malarial organism, and most unpleasant symptoms are developed.

2. Quinine should not, in my opinion, be administered by the mouth except in solution; dilute sulphuric acid I have found the best solvent. It can easily be understood that the gastric juice, etc., in the stomach will not be in a normal state when malaria is present or where there is a high temperature; and the quinine not only does not get dissolved, but becomes an irritant to such an extent that I have seen men almost dying from the effects of the so-called remedy.

3. Quinine should, when possible, be given before a rise in temperature; when the temperature is high it causes agonizing headache.

4. Quinine should not be given on an empty stomach. After an experience of over twenty years in malarial countries—Rhodesia, Northern Queensland, parts of America, and China—I have long ago come to the conclusion that tablets of quinine or the powder are unsatisfactory, and more

often than not nothing but irritants, more particularly in cases weakened already by other sicknesses, etc., in a hot climate.

BRONCHIAL ASTHMA.

DR. J. E. MIDDLEMISS, Medical Officer to the Leeds Mental Deficiency Committee, in a letter elicited by Dr. Jepson's memorandum on bronchial asthma (November 17th, p. 650), states that he was particularly interested in the parallel drawn between bronchial asthma and epilepsy. The nervous factor underlying the majority of cases of bronchial asthma, he thinks, is recognized theoretically in medical literature, though not exemplified in some of the therapeutic measures advocated. The treatment by vaccines, for example, he continues, takes no account of this factor; the use of adrenalin injections, on the other hand, which cause constriction of the vessels supplying the bronchial mucosa admits by implication the nervous factor, or at least is compatible with that explanation. Moreover, the practice of removing nasal growths and obstructions in this condition which act as reflex causes of irritation is based on the same principle, and the fact that such operative procedures are frequently nugatory only emphasizes the preponderating importance of nervous instability as the essential cause. None of these forms of treatment, however, take sufficient account of the neuropathic constitution as a whole, but the success which attended the treatment of a case by hypnotic suggestion reported in the *BRITISH MEDICAL JOURNAL* for 1914 (page 194) encourages a more extended trial of this form of treatment. Not all cases will prove amenable to suggestion, but where it can be employed it furnishes a ready means of combating the mental distress, restlessness, dreads, and apprehensions which are so frequently associated with this complaint, and perpetuate its symptoms. As it is possible in susceptible subjects to produce blisters on the skin by hypnotic suggestion (see paper by Dr. Arthur Hadfield, *Lancet*, November 3rd, 1917), there would seem to be no reason why the turgescent bronchial mucosa should not be influenced by suggestion in an opposite direction.

Bronchial asthma and epilepsy are both dependent on a fundamental instability of the central nervous system, but there the comparison ends; for the same remark applies to most functional neuroses, including some forms of chorea (see paper by Dr. Ivy McKenzie, *Glasgow Medical Journal*, June, 1915). Apart from the obvious difference in the gravity of the symptoms and the severity and extent of the nervous disturbance in epilepsy, it may be remarked that the latter disease is practically uninfluenced by suggestion. Moreover, the evidence of a relation between epilepsy and the true psychoses is far stronger and better established than in the case of asthma. The exhibition of potassium iodide has long been customary in this affection, and it usually causes relief of the immediate symptoms, probably, as Dr. Jepson suggests, by producing a "flow of watery mucus from the bronchial tubes." One wonders, however, whether in the last resort this is a desirable or even a rational procedure. Assuming that the symptoms are dependent on congestion and turgescence of the bronchial mucosa, efforts should be directed rather in the opposite direction. Anything which tends to irritate the lining of the bronchi would appear to be contraindicated, even though, as in this case, it procure a temporary relief of symptoms. The practice of electrical stimulation of the nasal mucosa in cases of paroxysmal sneezing is interesting in this connexion, the final object in this case, too, being the promotion of a state of relative insensitiveness of the lining membrane of the nose.

STATE PROTECTION FOR THE APPENDIX.

EVERYTHING is protected nowadays, and it is therefore not surprising to read that an American legislator has drawn up a bill for the preservation of the human appendix. He invites the South Dakota Legislature to place that troublesome survival under State control. He proposes that every appendix removed should be sent to the State laboratory for examination by the official pathologists. If they decide that the removal was justified, nothing further happens; if otherwise, the surgeon gets no fee. The measure is well enough conceived as a check on the over-zealous operator. But it may not unreasonably be asked why the appendix should be singled out for preferential treatment. Is there to be no legislative protection for the tonsil? Or for the teeth against the militant dentist, with his ever lengthening list of disasters due to evil conditions of the gums and other parts within the sphere of his activity?

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *posteo restante* letters addressed either in initials or numbers.

EPITOME

OF

Current Medical Literature.

JULY TO DECEMBER, 1917.

London :

PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
429, STRAND, W.C.

INDEX TO THE EPITOME FOR VOLUME II, 1917.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

- A.**
- Abdominal wounds, treatment of (R. Bastianelli), 21
- Abscess, artificial (Attilio Ascarelli), 5
- Adrenal indigestion (Loeper, Beuzard, and Wagner), 50
- ADRIAN: Electrical tests in peripheral nerve injury, 48
- Alcohol, local injections of, in neuritis (J. A. Sicard), 44
- ALEXANDER, Captain J. B.: Gunshot wounds of chest, 37
- Amnesia, malarial (De Brun), 47
- Amoebiasis, intestinal, persistence of (MacAdam and Keelan), 61
- Antiseptics, alternating use of (Charles Richet), 22
- Appendicitis and syphilis (Gaucher), 25
- Artificial abscess (Attilio Ascarelli), 5
- Artificial conjunctivitis (Van Schevensteen), 9
- (J. Bollack), 10—(Attilio Ascarelli), 11—(Mario Condorelli-Francaviglia), 12
- Artificial otitis (G. Gradenigo), 7—(Attilio Ascarelli), 8
- Artificial skin eruptions (Milian), 2—(P. Sabella), 3—(M. Carruccio), 4
- Artificial diseases. *See also* Simulation
- ASCARELLI, Attilio: Artificial abscess, 5—Skin lesions produced by caustics, 6—Artificial otitis, 8—Artificial conjunctivitis, 11
- B.**
- Bacillus welchii* infections, serum treatment of (C. G. Bull), 62
- BASTIANELLI, R.: Treatment of abdominal wounds, 21
- BAZAN: Prolongation of immunity against tetanus, 27
- BEUZARD: Adrenal indigestion, 50
- "Big belly" in soldiers (Désiré Denéchau and Henry Mattrais), 30
- BINET, Leon: The soldier's heart in war, 18
- BLUMER, George: Simulation of diabetes mellitus, 13
- BOLLACK, J.: Artificial conjunctivitis, 10
- BOUTET, André: Chloroform in the re-education of functional deaf-mutes, 43
- BULL, C. G.: Serum treatment of *Bacillus welchii* infections, 62
- C.**
- Cancer of cervix after subtotal hysterectomy ("Ralph Worrall"), 65
- "Captivitis" (Ch. Julliard), 33
- CARRUCCIO, M.: Artificial skin eruptions, 4
- CASTEL: Labyrinthine concussion, 40
- Caustics producing skin lesions (Ascarelli), 6
- Cerebro-spinal fluid, ferments in (E. Leschke and L. Pincussohn), 28
- Cerebro-spinal fluid in mumps (Tockmann and Luce), 15
- Chest, gunshot wounds of (Colonel A. B. Soltau and Captain J. B. Alexander), 37
- Chloroform in the re-education of functional deaf-mutes (A. J. Rayneau and André Boutet), 43
- CHRISTIAN, A.: Nervous symptoms in polycythæmia vera, 46
- CONDORELLI-FRANCavigLIA, Mario: Artificial conjunctivitis, 12
- Conjunctivitis, artificial (Van Schevensteen), 9—(J. Bollack), 10—(Attilio Ascarelli), 11—(Mario Condorelli-Francaviglia), 12
- COURBON, Paul: Psychology of simulation, 1
- D.**
- Deaf-mutes, functional, chloroform in the re-education of (A. J. Rayneau and André Boutet), 43
- DEBAT: Cheap dressings, 57
- DE BRUN: Malarial amnesia, 47
- DE NAPOLI, F.: Artificial pemphigus, 52
- DENECHAU, Désiré: "Big belly" in soldiers, 30
- Diabetes mellitus, simulation of (George Blumer), 13
- Dressings, cheap (François Debat), 57

AN EPITOME OF CURRENT MEDICAL LITERATURE.

Simulation of Disease.

1. The Psychology of Simulation.

LAIGNEL-LAVASTINE and PAUL COURBON (*Paris méd.*, July 7th, 1917), who begin by defining "simulation," say that all functional or organic disturbances which have their origin in the conscious will of the patient are simulated. They distinguish three categories: (1) Feigned somatic disorders, comprising self-inflicted mutilations or injuries, and self-induced diseases; (2) feigned functional disorders; (3) feigned functional disorders grafted on genuine organic disease. In making a diagnosis the question is whether there is or is not intent to deceive. This is difficult, because every man's inner life is the scene of so many involuntary and unconscious lies that no one can tell the determinations even of his own actions with certainty. Between the man who is genuinely ill and the simulator there is an insensible gradation. The pure type of simulator is the man whose conduct appears to be solely determined by the deliberate intention of avoiding combatant dangers. What the authors call a "mitigated" type is represented by men whose mental constitution causes a certain lessening of resistance to danger. The pure simulator is without excuse; he is a mere selfish coward. In the mitigated type some allowance must be made for mental constitution. The man is moved by the feeling that he cannot face danger. There are several varieties of this type: (a) Emotional, common in those who do not believe in war and are unable to adapt themselves to its conditions; (b) the hypochondriac, who thinks his health unequal to the fatigues of a campaign; (c) the man who holds that he has a right to claim exemption either because he has done enough or because he considers that he would be more useful in a less exposed post—especially common among those who have been at the front and sent back for some injury or sickness; (d) the suggestionable, who simulates at the instigation of his family or friends; (e) the simulator by reaction, who thinks it necessary to keep up a morbid condition in order to prove that he has been wrongly charged with malingering. When real disease or injury is made to appear worse than it is by simulated functional trouble the exaggeration is often more or less unconscious. Under the name of *persévérance* the authors describe feigned disorder following real sickness or injury. In the pure type the patient does exactly the opposite of what is necessary for cure; in the mitigated type the man does not actively keep up his disability but does nothing to get well. In pathomimia, which is the artificial production of disease—for instance, by inoculation—there is also a pure type in which the patient acts with deliberate intention to deceive, and a mitigated type in which the man while wishing to deceive is also to some extent the victim of his own perverted imagination. There are active, apathetic, and sensitive simulators. To the first category belong men who multiply their devices, and thus increase the risk of detection. Instead of waiting till their fraud is exposed they are eager to prove their innocence, and in so doing stumble into pitfalls made by their ignorance of symptomatology. The apathetic acts by the force of inertia; he awaits instead of seeking investigation, and is content to make a passive show of good faith. The sensitive generally tries to avoid examination but submits readily to treatment. The cause of his simulation is separation from home. He acknowledges that he is not ill, and returns without much objection to his unit, but on the march his courage fails, and he again declares that he is ill and tired of life. He faints on the road, and some more or less moving testamentary document is found on him declaring his determination to kill himself. Though there is much hypocrisy in his conduct, it may be associated with a certain amount of sincerity. So while the active simulator is disliked, and the apathetic becomes a bore, the sensitive almost inspires sympathy. While the pure simulator, the constitutional coward, is always a fraud, the others are simulators only owing to circumstances more or

less persistent, but which are always due to some weakening of energy. Many of the authors' patients had behaved well in battle, and even won the Military Cross. Their subsequent failure was due to a change of disposition. Their moral energy, conspicuous at first, became exhausted.

2. Artificial Skin Eruptions.

MILIAN (*Paris méd.*, May 5th, 1917) classifies artificial eruptions as follows: Pustular forms of dermatitis, bullous or phlyctenular eruptions, eczematoid dermatitis, oedemas, factitious ulcers of the legs, and sham mucous patches. Of these, pustular dermatitis is the most common. The elementary lesion is a pustule varying in size from a pin's head to a millet seed; the skin around is healthy or may be slightly inflamed. The pustules are usually fairly abundant but gathered together into two or three patches. These patches are almost always situated on the hairy parts of the face, often on the ears and neighbouring parts, or on the front and left surfaces of the thigh. An important diagnostic point is that the pustules are all in the same stage of evolution, the whole process taking four or five days. For the production of these eruptions croton oil and thapsia are chiefly used. Artificial phlyctenular dermatitis is not common, as it is too easily recognized; the lesions are true blisters. The men do not usually present themselves till the phlyctenulae have shrunk, leaving inflammatory lesions. Sometimes they come in the stage of desiccation and the lesions suggest burns of the second degree. But the patient will not admit any history of burning, and by insisting that the affection came on of itself he excites suspicion. Bullous dermatitis in a stage that might simulate pemphigus is rare. These eruptions are produced by blistering fluids, and the man as a rule aggravates the lesions into true sores. Eczematoid dermatitis is usually seen on the face; the eyelids are generally affected, less frequently the thighs and groin. The skin is red and oedematous, the eyelids often so puffy as to close the eye. Cases of this kind are often sent to hospital with a diagnosis of erysipelas. But the absence of fever and malaise, and of enlarged glands under the jaw or pain on pressure of the patch, makes this diagnosis untenable. The lesions subside in four to six days; the skin quickly becomes quite normal, without any trace of branny desquamation or gloss. But this kind of artificial eruption is difficult to distinguish from dermatitis produced by accidental contact with an irritating substance. The malingerer, however, never reveals the nature of the substance used, and Milian has never succeeded in identifying it; he has heard, however, that the lesion can easily be produced by rubbing the face or forearms with automobile oil. Oedema is produced by tying a wide flat strap on the forearm or the lower part of the leg during the night. The fraud is easily revealed by the mark of the strap on the skin. Artificial ulcer is difficult to recognize. The men come with a history of an injury which has broken the skin. The sore shows no tendency to heal in spite of careful dressing for many weeks. Its refractoriness then excites suspicion of syphilis, and appropriate treatment is employed for three months without result. Milian lays down the principle that such obstinate sores in young men properly treated may, in the absence of special conditions, be regarded as artificial. They are generally situated on the legs at places within reach of the patient's right hand. They are never at the seat of election of varicose ulcer, the lower third of the leg, especially above or behind the internal malleolus. New ulcers appear, the mode of onset serving to indicate their origin. They are caused by a blistering substance or a caustic agent. The diagnosis from gummatous ulcers is the more difficult because sometimes the malingerer is a syphilitic who has in the course of treatment acquired a knowledge of the disease, which he is clever enough to apply for the purpose

of deception. Artificial ulcers have also to be distinguished from the chronic ulceration following ecthyma or infected wounds. In artificial sores which are constantly under the action of caustics there are no granulations. Varicose ulcers, with their pigmented or eczematoid border and their dull, smooth base, have no resemblance to artificial eruptions. A valuable aid to diagnosis is an occlusive dressing; it is sufficient to keep the sore out of the patient's reach for a fortnight. Collodion is the best application for the purpose, but as the retained pus may cause complications, the doctor should himself put on the dressings, sealing up the ends, or keeping a watchful eye on the bandages, after carefully noting the turns and manner of fixing; in this way it will be seen whether it has been undone. Another diagnostic device is to induce the patient to give himself away by producing fresh eruptions. The doctor, on examining the original lesion, says in the man's hearing, "I am surprised that there are not similar lesions five or six centimetres lower, as I have always seen in such cases during the war." Next day lesions duly appear in the place indicated. Artificial mucous patches are produced with the lighted end of a cigarette. They are generally narrower than a cigarette, as the whole end is seldom applied. The lesions are on the left side, and situated on the inner surface of the lower lip not far from the commissure, in the cheek, or on the velum, never on the pillars of the fauces or the tonsils. They consist of rounded, shallow ulcers with a smooth yellowish base, without inflammatory border, raised papules, or surrounding leucoplasia; these features are important in excluding syphilis.

3.—P. SABELLA (*Policlinico*, May 27th, 1917), from observations among men in the fighting line extending over many months, classifies artificial skin eruptions in two categories according to the substances used to produce them. One group includes those in which the irritants were vegetable powders obtained by the trituration of roots or bark or from the juice or oil of the seeds of some ranunculaceous or euphorbiaceous plants. The sudden appearance of the lesions, and the local symptoms, which are sometimes severe, contrast sharply with the complete absence of general reaction. As a rule, in less than twenty-four hours after the application of the irritant there appears a diffuse erythema, often suggestive of erysipelas. The erythematous skin becomes the seat of numerous miliary vesicles due to simple detachment of the epidermis; the walls are thin and the contents like pus. The affected skin is not very painful on pressure. If infection and eczematization are prevented, cure quickly takes place. The vesicles become flaccid and dry into thin crusts, the swelling of the skin subsides, and the epidermis desquamates. Sabella for the first two or three days uses wet dressings of a 3 per cent. boracic lotion; when the discharge has dried up he applies zinc ointment. In most cases the eruption is produced on the face, but Sabella has seen it on the limbs, the trunk, the pubes, the genitals, and on the ear. Such substances applied to the scrotum and inguino-scrotal folds cause inflammation of the skin, which very easily becomes infected and takes on the characters and course of intertriginous or impetiginoid eczema. The second group of artificial eruptions comprises those due to caustic applications; the lesions range in degree from superficial erythema to grave necrosis. When produced by caustics in solution, they may be disseminated in large patches over large surfaces; occasionally they are true burns caused by boiling water or lime. Others occur in the form of sharply circumscribed bullae and phlyctenulae, or patches of cutaneous necrosis. For the most part they are localized on the lower limbs, either because those parts are easily accessible or because injuries in that situation need rest. The bullae and phlyctenulae have sero-fibrinous and sero-haemorrhagic contents, and form adherent crusts; the underlying derma either becomes covered with epithelium beneath these or heals by granulation when the crust separates. The sloughs from canterization of the third degree are thicker and more adherent to the derma or subcutaneous tissue; they separate very slowly, and the sore heals by granulation.

4.—M. CARRUCCIO (*Policlinico*, May 27th, 1917) saw in a skin department during the autumn of 1915 and the following winter more than one hundred soldiers with an acute dermatosis of practically identical nature. Many of the cases came from country places near Rome, where the men had been on leave. Instead of returning to their units at the front, they reported themselves sick. The skin affection was not accompanied by general reaction or

visceral disturbance. Some of the men confessed that the lesions were produced by the application to the skin of vegetable substances such as pounded root of *Daphne gnidium* and the juice of the cactus leaf, which is very common in the gardens of the district. These substances were applied by gentle friction with practised hands over the whole body, rarely on circumscribed areas on the legs or trunk. The applications caused neither general disturbances nor severe local pain such as are produced by mineral acids, croton oil, or turpentine. The eruption begins as a somewhat intense erythema, limited to the site of application. This stage reaches its full evolution within twenty-four hours. Then there sets in a papular phase in the form of elevations about the orifices of the follicles with marked perifollicular infiltration. If this passes on to resemble an acute toxic erythema or a lichen tropicalis, very numerous small superficial vesicles nearly always develop, containing more or less pus. In some cases they tend to become confluent. The pustules, which are mostly seen on hairy surfaces, are due to infection with *Staphylococcus pyogenes aureus*. Carruccio treated all his cases by repeated applications of pure phenol, gram 1; camphor, grams 11; in vaseline oil, grams 100. This checked the inflammatory process and banished the hyperaemia. In the vesiculo-pustular stage the purulent exudation quickly dried up, leaving small crusts. The follicular infiltration subsided gradually; in most cases, after the redness had disappeared, there was still some elevation with brownish discoloration limited to the orifices.

5. Artificial Abscess.

PROFESSOR ATTILIO ASCARELLI (*Policlinico*, June 3rd, 1917) says that among the most common forms of lesions inflicted on themselves by Italian soldiers are abscess and phlegmon produced by injections of petrol, turpentine, benzine, chloride of lime in benzine solution, etc. The parts selected are particularly the lower limbs, most commonly the calf, the instep, and sides of the knee; not infrequently abscesses are seen on the buttocks. Most often the patient presents himself shortly after the injection, and ascribes the swelling to a fall with twisting of the knee or foot, or to contusion from a blow on the knee, or to a therapeutic injection. His general condition is good, the temperature is very slightly raised, and the pulse is all but normal. In a few days, even if the abscess is not opened, the temperature falls and remains low, even in the evening. There is always slight albuminuria without casts but with a few well-preserved red corpuscles. For two or three days the affected part remains red and slightly oedematous; there is no fluctuation, but a doughy feeling on palpation, and sometimes emphysematous crepitation. Local pain is slight. There is no accompanying lymphangitis or lymphadenitis, unless septic complications occur, as they do not infrequently. Nor is there ever any ecchymosis or solution of continuity. After a few days the redness increases and tends to become cyanotic; tension is more manifest; there is no fluctuation, but a peculiar feeling of colligation. The swelling is quite circumscribed, with sharply defined borders; the skin tense and glazed. By exploratory puncture a few droplets only of blood-stained pus can be withdrawn. In slight cases the swelling subsides, and in ten or twelve days all becomes normal; on the other hand, in grave cases the skin becomes more tense and more glossy, and there is a tendency to ulceration. Incision, which even in moderate cases should be performed early, gives exit to a very scanty amount of pus and well-preserved liquid blood, with which are mixed many necrotic fragments of subcutaneous tissue, muscle, and even fascia. After incision inspection will show that the tissues are dissected along the intermuscular spaces. In the great majority of cases the affection runs a favourable course. Sometimes, when much of the irritant substance has been used, the tissues are extensively stripped up between the muscular bundles. Even in such grave cases general complications are not frequent and lymphadenitis is rare. Sometimes recovery is much delayed owing to great loss of tissue, and many patients lie in hospital for many months; sometimes they remain partially disabled. The lesions do not differ much whatever the agent used, but they are particularly severe when produced by petrol. The treatment is the same as that of ordinary abscesses, but reliance must be placed on an exclusively aseptic dressing, no disinfecting substance being employed. Abscesses are sometimes, though more rarely, produced by injection of faecal matter. They are seen chiefly on the legs and neighbouring parts. The result is generally a deep phlegmon accompanied by grave sepsis, general and local. Detection of the cause may be very difficult.

Sometimes, on opening the abscess, a faecal smell is perceived, just as the odour of turpentine or petrol may be detected in the previous cases, and the presence of a red raised point may mark the track of the needle. Complete recovery takes place only after several months. When injections of faecal matter mixed with petrol or benzine are used, the symptoms due to the chemical agent predominate; hence diagnosis is more difficult.

6. Skin Lesions Produced by Caustics.

ASCARELLI, in the article summarized above, deals further at some length with self-inflicted lesions caused by chemical caustics. An excoriation is produced by friction and then a strongly concentrated mineral acid or alkali is applied for some time. The agent most frequently used is soda or potash lye, sulphuric or hydrochloric acid, more rarely chloride of zinc. By the application of these substances an eschar is produced the origin of which is recognized without much difficulty. The places selected are the dorsum of the foot, the back of the hand, and the front of the leg. The patient generally attributes the affection to a contusion caused by a heavy object falling on his foot or the blow of a hammer on the hand. He comes in excellent condition, and neither general inspection nor examination of the urine reveals anything (syphilis, diabetes, syringomyelia, varix) that explains the formation of eschars. The lesions are single or multiple, definitely circumscribed, more or less circular, with sharp margins, sometimes festooned, without trace of oedema or streaks of lymphangitis. The lesion is covered with a dirty grey or blackish slough, very adherent and of leathery dryness. When this has separated a punched-out ulcer with thin borders is revealed; the base is torpid and lardaceous with small necrotic patches, and the sore has the aspect of a trophic ulcer. There is hardly any pain, and functional changes are very rare. Under treatment with physiological solution cure takes place in fifteen to twenty days. After cure there remains a roundish, slightly retracted cicatrix; it is not adherent and is brownish in colour. Mixed forms of self-inflicted contusion and voluntary cauterization are also seen. The patient, before applying the chemical agent, prepares the ground by rapid and repeated blows, which cause a hard oedema. In these cases the eschar lies in the middle of a zone of infiltration of the cutaneous tissues in the form of a hard irregular patch, subcyanotic in colour, or of ecchymosis or punctiform haemorrhages around the necrotic zone. It is very difficult to identify the substance used, as, whatever it is, with the death of the tissues to which it has been applied it produces in two or three days a blackish eschar. These eschars may sometimes be confused with ischaemic eschars. The differential diagnosis must be based chiefly on the history. For the production of a limited contusion with necrosis of the tissues it is generally necessary that the body causing the bruise should be of special shape and should be pressed on the part for a time sufficient to cause intense ischaemia.

7. Artificial Otitis.

G. GRADENIGO (*Giorn. della R. Accademia di Medicina di Torino*, January-February, 1917) says that artificial lesions of the ear are common. Purulent otitis is simulated by the introduction into the ear of substances resembling pus (honey and milk, soft cheese, clotted milk, putrefied yolk of egg, juices of various plants); polypus is simulated by means of the viscera of small animals. These frauds are easily detected by the speculum; if there be any doubt, the nature of the foreign liquid will be shown by microscopic examination. As a rule the affections produced artificially are suppurations; much more rarely the lesion is a perforation of the tympanic membrane which requires nerve and a practised hand. It is easy to set up suppuration of the ear; owing to the thinness of the lining integument, even simple irritants may cause more or less deep lesions, which are liable to suppurate. The cases are divisible into two groups according as the membrane is intact or already perforated as a consequence of an old cured otitis media. In the latter case, when there is more or less extensive dry perforation, the delicate mucous lining of the tympanic cavity is directly exposed to the irritant action of external agents; the instillation into the meatus of a slightly irritant liquid will cause reinfection of the middle ear—a true acute purulent otitis clinically indistinguishable from the real affection. Usually there is no perforation, and then the lesions vary with the nature of the agent used and the site of application. Various solid agents are employed, such as cantharides powder, blistering plasters, small rolls

of paper impregnated with irritating soap, etc. Powders made of tiny fragments of skin from horse-combings are very irritating and form a favourable medium for the development of aspergillus or other mycoses. If the caustic is powerful (concentrated mineral acids or boiling liquid) the membrane is perforated and sometimes destroyed; serious changes are produced in the walls of the tympanic cavity, in the labyrinth, and the facial nerve. Such lesions, however, are seldom seen in soldiers who know the pain of the manœuvres required to produce them and the risks they entail. In the majority of cases moderately caustic substances are employed and only a diffuse external otitis is produced. In the present war benzine, which is easily procured from automobiles, is much used. Among other agents are turpentine, croton oil, dilute acids and alkalis, or perchloride of iron. Irritant vegetable juices are in common use; less frequently tobacco juice or match-heads are employed. In the other group, which is perhaps the more numerous, otitis is produced not by instillation but by the application of caustics to the orifice. This causes ulceration, the lesions being pretty regularly arranged around the meatus, and extending for $\frac{1}{2}$ to 1 centimetre on the walls of the cartilaginous part, and also involving the concha and the tragus. They do not reach the deeper parts of the meatus or the membrane; this, says Gradenigo, is a point of the utmost importance. In slight cases there may be only transient superficial ulceration. A characteristic feature is that the surface is at first covered with a whitish pulpy mass, consisting of macerated epidermis and pus; this is very adherent, and its removal lays bare an ulcerated surface, which bleeds readily. If the caustic action has been severe a whitish eschar forms, which separates many days after the injury, exposing the deep parts of the derma and sometimes the cartilage. In that stage there is more or less violent inflammatory reaction of the adjoining parts of the walls. Suppuration occurs, and later granulations, which grow inwards and quickly tend to block the lumen of the meatus. If left to themselves the lesions give rise to stenosis and even complete obliteration of the passage. The presence in recent cases of eschars, particularly when they extend all round the meatus, the fact that the burns are hardly ever limited to the meatus but also involve the concha and sometimes the preauricular region, the cheek or the chin, and the intense inflammatory reaction, are sufficient for diagnosis. After a few days, however, when the sloughs have come away leaving ulcerated surfaces, there may be difficulty. If the lesions are sharply limited to the meatus and external parts and the tympanic membrane is intact, artificial otitis may be diagnosed with certainty. There is more difficulty when, as happens after the instillation of caustic liquids, the walls of the meatus, even in the deeper parts, participate in the morbid process, and there is a perforation of the membrane with suppuration of the cavity. It must be borne in mind that under the conditions of active service and the neglect of the most elementary personal cleanliness a chronic purulent otitis in a soldier easily becomes acute, and the discharge stagnating many days, or even weeks, in the passage causes inflammatory lesions of the walls and meatus. As such men are as a rule in the upright position during the day, the irritating secretion collects in the dependent parts of the middle ear, and the greatest changes are seen on the inferior wall. Ulceration on the upper, particularly the anterior, wall of the meatus, should give rise to suspicion. An important feature of artificial external otitis is the rapidity with which cure of the lesions takes place when further irritation is prevented by the application of suitably marked starched bandages. Genuine ulceration is made worse by this means owing to the retention of pus. The unwillingness of malingerers to furnish information as to the origin and symptoms of their affection is in itself a suspicious sign.

8.—In Professor ATTILIO ASCARELLI'S experience (*Poli-clinico*, June 3rd, 1917) artificial otitis is very common. The artificial lesions are often grafted on a true chronic otitis. The patient always says that he has had inflammation of the ears since childhood and that the disease has been stirred up into new activity by wet, cold, and fatigue. At first the process is accompanied by evening fever of moderate intensity. In the early period diagnosis is easy as the lesions in the external meatus and pinna are characteristic. An eschar consisting of a grey, dry adherent substance lines the outer and inferior part of the meatus all round. Sometimes, particularly if the caustic has been introduced deeply drop by drop, there is perfora-

tion and destruction of the tympanic membrane. Secretion is generally scanty. Externally, traces of burning may be seen in the form of small phlyctenulae, and eczematoid eruptions on the pinna, tragus and antitragus are prolonged on to the lobule exactly as if a liquid had flowed from the interior to the outside of the ear; sometimes they extend to the cheek. When the eschar has separated, which occurs on the average in a week or a fortnight, a clean superficial sore is left which quickly cicatrizes. If the lesion has affected the whole circumference of the meatus to a certain depth, cicatrization causes stenosis or even complete closure of the passage. If these secondary changes do not occur after separation of the slough the diagnosis is difficult, either because the appearances differ little from those of an ordinary purulent otitis media, or because a genuine chronic otitis again becomes active. In any case the one-sidedness of the lesion and the situation of the cicatrix on the outer part of the meatus are points of great importance. Complications, apart from perforation of the membrane, which is somewhat frequent, and from the occurrence of suppurating otitis media, are not rare and occasionally are very serious. In several cases Ascarelli has seen facial paralysis, in others complete destruction of the whole meatus, in others again mastoiditis. Treatment is simple. Until the separation of the slough all that is required is a protective gauze dressing of the walls of the meatus. After separation the sore should be dressed with gauze smeared with some aseptic ointment to promote epithelialization. Special treatment is indicated for otitis media, perforation, mastoiditis, or other complications.

9. Artificial Conjunctivitis.

VAN SCHEVENSTEEN, in *La Clinique Ophthalmologique* (abstract in *Archives médicales Belges*, March, 1917), says there are two types of artificial conjunctivitis—one produced by powdered ipecacuanha, the other by agents of very various kinds which produce anomalous lesions. The introduction of ipecacuanha causes intense injection, with chemosis; there is only slight secretion. The eyelids are much swollen, especially about the lower cul-de-sac in which the irritant is generally placed. The reaction subsides in a few days, but the mucous membrane long retains the salmon tint that reveals the origin of the lesion. Subsequent applications are better tolerated whilst producing still more characteristic appearances: considerable thickening of the conjunctiva of the lower cul-de-sac, salmon tint, blurring of vascular outlines. Lastly, ectropion with lacrymal stasis supervenes. If the applications are repeated these phenomena persist for a long time. In view of the well marked character of the inflammation it is unnecessary to seek for ipecacuanha with the microscope. Complete recovery is the rule when the application of the irritant is discontinued. Further treatment by cold compresses, and an occlusive collodion dressing is all that is required. In the case of other agents used to produce conjunctivitis the duration and abnormal course of the affection should arouse suspicion.

10.—J. BOLLACK (*Presse méd.*, abstract in *Arch. méd. Belges*, March, 1917) says that the cytological examination of the secretion in ten cases of conjunctivitis, presumably artificial, revealed in all the existence of numerous polynuclear eosinophiles. Localized eosinophilia is exceptional in ordinary conjunctivitis, and it never attains the intensity of that observed in the artificial affection; therefore eosinophilia may be taken as strongly suggestive of the latter. It comes on relatively late. Its intensity is proportionate to the duration of the affection, and especially to the number of applications of the irritant. It does not depend on the nature of the agent (ipecacuanha, insecticide powder, etc.). The other clinical signs suggestive of an artificial origin are, almost unfailing onesidedness, frequency of eczematous lesions about the external commissure and the lower lid, predominance of the lesions in the lower part of the conjunctiva, refractoriness to treatment, especially if the patient is not kept under close supervision, scantiness of the secretion, total or almost total absence of pathogenic germs in the secretion, and the military antecedents of the patient.

11.—ATTILIO ASCARELLI (*Policlinico*, June 3rd, 1917) says that artificial conjunctivitis is very common in the Italian army. Among the irritants employed for its production the most common are seeds of the castor oil plant and powdered ipecacuanha; infusion of tobacco and grains of sand are also used. The ricinus seeds are shelled and powdered, and a little of the powder is introduced into the

conjunctival cul-de-sac. The lesions with which the men present themselves are slight oedema and reddening of the eyelids, with muco-purulent discharge. The conjunctiva of the lower lid is hyperaemic and thickened, with whitish-grey false membranes, which on removal leave superficial loss of substance, some chemosis, and a notable diminution of transparency. Generally nothing of this kind is seen on the upper lid, and this limitation of the process with the formation of small sloughs on the conjunctiva of the lower lid is characteristic. Very slight eczema in the periorbital zone is common. The voluntary injury is often grafted on a true chronic conjunctivitis, distorting its characters, and making the diagnosis difficult. The course of the affection is very rapid. The symptoms subside in six or seven days, leaving, however, small whitish cicatricial striae on the lower lid. Very often the fraud is repeated when recovery is almost complete, and sudden relapses, with violent exacerbations, take place without apparent cause. If this is continued, the conjunctiva of the upper lid becomes hyperaemic and thickened, and shows small granulations. The treatment is the same as that of ordinary conjunctivitis; sometimes a few applications of a simple lotion are sufficient. As a precaution against repetition starched bandages may be placed over the eyes, sealed and signed. More than anything else, however, strict supervision of the patient is necessary.

12.—MARIO CONDORELLI-FRANCaviglia (*Policlinico*, June 3rd, 1917) gives details of a case of acute catarrhal conjunctivitis in a soldier produced by the ash of castor oil seeds, and records some experiments on the effects of that agent. He found that the toxalbumin contained in the seeds exerts a very powerful irritant action on the conjunctiva, manifesting itself in an acute catarrhal muco-purulent inflammation. This affection differs from the natural disease in the unequal distribution of the inflammatory process which is more intense on the lower lid and corresponding cul-de-sac. The bulbar conjunctiva participates in the process, but only to a moderate degree in ordinary cases; in the more serious forms there is chemosis and a raised border round the cornea. The hyperaemic conjunctiva has the colour of washed flesh, and not the scarlet of true inflammation. In serious cases, when the inflammation is intense, small eschars in the form of whitish transverse striae are seen on the lower lid and in the corresponding cul-de-sac. Oedema of the lid may or may not be present, according to the intensity of the inflammatory process. Contrary to what occurs in cases of genuine catarrhal conjunctivitis, the artificial form may be one-sided.

13. Simulation of Diabetes Mellitus.

GEORGE BLUMER gave particulars of a case of simulation of diabetes mellitus in the *Boston Medical and Surgical Journal* of January 13th, 1916. Blumer's case was a married Irish-American woman of 33, who twenty months before rather suddenly developed pruritus vulvae. Examination showed an absence of general physical changes. The fact of simulation was finally proved by testing a catheter specimen of her urine. Simulation of diabetes mellitus may take one of three forms—(1) the addition of sucrose to the urine, (2) the addition of glucose, or (3) the production of artificial glycosuria by the consumption of phloridzin or phloroglucin. Detection of the simulation depends in the first place on the occurrence of some suspicious factor; this simulation is commoner among soldiers than civilians. Detection of sucrosuria is simple if the urine be examined fresh; in this case there is no inversion of the sucrose and no copper reduction, and we have a high specific gravity urine with large amounts of dextro-rotary sugar shown by the polariscope, which on artificial inversion splits to dextrose and levulose. Examination of a catheter specimen in the female and of urine passed by the male patient in the examiner's presence proves the fact of simulation. Detection of feigned glycosuria is more difficult if the patient is intelligent enough not to put in too much glucose. Nowadays patients use a chemically purer product than formerly. When suspicion is aroused, catheterized specimens will clear up the case; but in a case recorded by Abeles and Hoffmann the patient actually introduced the glucose into her own bladder. Therefore the catheterized specimens must be obtained when the patient does not suspect their purport. Finally, if there be suspicion that an artificial glycosuria is being produced by consumption of phloridzin or phloroglucin, the patient should be isolated from possible supplies of these drugs.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

14. The Treatment of Hyperthyroidism.

GRIER (*Amer. Journ. of Roentgenol.*, June, 1917) divides cases of hyperthyroidism into four groups: (1) Simple hyperthyroidism, or a persistent exaggeration of the physiological hyperthyroidism which occurs at adolescence and is occasionally seen in adult life during the menstrual period or during pregnancy; (2) acute exophthalmic goitre; (3) chronic exophthalmic goitre; (4) hyperthyroidism developing on an old goitre, either hypertrophic or cystic. In the first group of cases operation is not only unnecessary but absolutely contraindicated. The author claims 100 per cent. of cures in this type of hyperthyroidism by x-ray treatment. Medical treatment is successful in the majority of such cases; x-ray treatment is satisfactory in practically all of them. In the second group, x-ray treatment is the most satisfactory; medical treatment is inadequate, and surgery unnecessary. These are the cases of exophthalmic goitre in which the patient is acutely ill, and in which the symptoms are gradually but progressively becoming worse. Out of 22 cases of acute exophthalmic goitre the author treated by x rays 20 were discharged as cured. In the third group the choice lies between x-ray treatment and operation. The x-ray treatment of these cases is apt to be slow, but there is not so much danger in producing a subsequent hyperthyroidism as by operation. The final choice of treatment in this class of chronic case will depend largely on individual circumstances. In the fourth group, where hyperthyroidism develops in an old goitre, x-ray treatment is only palliative. The danger of producing myxoedema is also greater here, and the proper treatment for these cases is surgical. As a whole the two factors which appear to have the greatest bearing on the prognosis under x-ray treatment are the length of time the condition has existed and the softness of the enlargement. Speaking generally, the longer the disease has been present and the harder the gland the greater will be the difficulty in obtaining a satisfactory result. Under x-ray treatment the first improvement is in the nervousness and in the pulse-rate. In the early stages of the disease, when the exophthalmos is largely due to engorgement of the blood vessels of the orbit, the exophthalmos also will disappear under treatment, but later in the disease, when the exophthalmos is due to deposition of fat in the orbit, it will not be influenced by x-ray treatment.

15. The Cerebro-spinal Fluid in Mumps.

THAT the meningitis which may complicate mumps is cytologically lymphocytic, like that now recognized to be characteristic of acute poliomyelitis, was pointed out in 1904 by Chauffard and Boidin. Among 635 soldiers with mumps transient meningeal symptoms were noticed in 23 per cent., and from cytological examinations of the cerebro-spinal fluid in sixteen of these cases MASSARY, TOCKMANN, and LUCE (*Bull. Acad. Méd.*, Paris, 1917, 3 sér., lxxviii, pp. 6-8) found that there was no relation between the gravity of the meningitic symptoms and the number of the lymphocytes—in fact, the clinical manifestations may be alarming when the number of lymphocytes is small. Further, examination of the cerebro-spinal fluid of forty other patients with mumps, but without meningeal symptoms, showed a lymphocytosis of the same character as in patients with meningeal manifestations, and clinical changes, such as an increased content of albumin lasting for a long time, thirty or even fifty days. These results are interesting because puzzling and await elucidation.

16. Changes of Voice and Speech in Shell Concussion.

N. WYROUBOW of Moscow says (*Rev. Neurologique*, November-December, 1916) that changes of voice and speech in war psychoses produced by shell concussion are,

as a rule, associated with marked impairment of hearing which, especially at the outset, may amount to complete deafness. The loss or impairment of hearing after concussion lasts from several hours to several weeks; where there is dumbness the hearing improves a little before or at the same time as speech is recovered. Changes in the voice or speech may be classified into: (1) Dumbness; (2) whispering speech; (3) falsetto voice. Patients belonging to the first category cannot utter any sound; most of them do not even attempt to make movements corresponding to the production of sounds; it is only by gestures, by shaking the head or tight closing of the lips that they are able to indicate that they cannot speak. Redness of the face due to play of the muscles betrays the efforts made. Wyroubow in three cases of complete dumbness observed weakening of the muscles of the tongue. Whereas deafness came on immediately after the concussion, dumbness might appear at different times. Most frequently its onset coincided with that of deafness, but not seldom the deafened patient began by calling out without hearing his own voice or that of others; only after some time did he become entirely unable to utter sounds. Deafness might last from four to eight consecutive weeks. Recovery of speech took place in different ways. In some instances the patient suddenly began to speak in his natural voice, a little fainter than before. This might occur under the stimulus of a strong emotion. Often, too, speech was restored by gently inducing the patient to pronounce sounds after the doctor. In other cases the man regained the power of whispering, and it was only by degrees that the voice became stronger. Of the other changes in speech whispering was most common; it came on at the same time as the deafness, immediately after the concussion or after a short interval, during which the patient spoke in shrill cries. Normal speech returned after a more or less prolonged period of dumbness. The rapidity of whispered speech was generally diminished, and the rhythm was usually irregular with interruptions and delays, and even well-marked stammering. Whispering speech might persist for several weeks, and recovery of the voice was slow; for a long time it remained feeble, and when rhythm was affected it still presented traces of the former irregularity. The falsetto voice might coincide with the onset of deafness, or come on a short time later. In either case it might last several weeks, but its duration was shorter than that of the whispering voice. The rapidity of speech was increased and the rhythm always irregular and interrupted. In other cases there was sharp disarticulation of words, amounting sometimes to real stammering. Recovery of normal speech in such cases is slow and gradual.

17. Urinary Disorders in Wounded Men without Organic Lesion.

PROFESSOR POUSSON of Bordeaux gives in the *Bulletin médical*, March 21st (abstract in *Journal de méd. et de chir. prat.*, May 10th, 1917), the results of a study of certain forms of urinary trouble without lesion of the urinary apparatus which he has seen fairly often in wounded men. The cases fall into various groups. When there is a lesion of the spinal cord the symptoms vary according to the seat of injury. In a second group of men in whom there is no trace of external wound but who have been exposed to detonations at close range the most common trouble is incontinence of urine; much more rarely there is retention, in some also there is pollakiuria. In these cases there is probably a hysterical element. In another group the trouble sometimes consists in retention, but in most cases there is incontinence of urine by night, sometimes also by day, more often pollakiuria. Most of these patients are old incontinent in whom the infirmity, which had ceased at the age of 18 or 20, returned on mobilization; they were all men aged from 25 to 30. The recurrence was

attributed to the general weakness consequent on fatigue, chill, and other physical causes, all these factors being combined with mental strain, which produced neurasthenia. It is not surprising that in persons in whom incontinence of urine had ceased on the establishment of a perfect balance of all organic functions as a result of physiological development, the equilibrium should be upset by the strain of war. In regard to the pathogeny of this variety of urinary trouble, the author thinks the patients should be classed with those suffering from commotion; similar treatment is therefore indicated, and they should be dealt with in the same way by the medical boards.

18. The Soldier's Heart in War.

AN abstract in *Rev. Neurologique*, November-December, 1916, summarizes observations by LEON BINET on the effects of war emotions on the cardiac rhythm. These show themselves in various ways. There may be no modification in the pulse, and no emotional reaction. More often on the explosion of a shell, a torpedo, or a mine, the heart's action is slowed, the pulse-rate falling to 60, as a result of excitation of the vago-bulbar system. In other cases stimulation of the sympathetic causes acceleration of the heart; this emotional tachycardia has been noted particularly in soldiers recently arrived at the front, and in men of "moderate" courage. War injuries, including concussion, also act on the cardiac rhythm. The emotional shock, haemorrhage, and pain combine to induce moderate tachycardia. This is the general rule, which does not, however, hold good for certain cases of wound of the head and chest. In some cranial cases a notable slowing of the cardiac rhythm (to 65 or 60, or even 55) occurs very shortly after the infliction of the wound; this symptom indicates the existence of serious lesions, and calls for immediate intervention. In the chest cases there is almost always marked tachycardia, unless the heart is involved, when there is sometimes progressive bradycardia. The nervous shock following explosion of a large shell at close range, without external wound, expresses itself by disturbances of varying character, including alterations in the pulse. In 56 out of 100 men exhausted by prolonged fatigue, slowing of the pulse was noted. The cardiac rhythm also varies in flying men. In a rapid ascent, and particularly in a sudden descent, the pulse is decidedly slowed. In such cases there is excitation of the vagus causing a so-called vago-bulbar syndrome (bradycardia, hypotension, tendency to syncope).

19. Traumatic Scarlatina.

S. KORACH (*Dent. med. Woch.*, January 18th, 1917) has contributed the following case to the literature of traumatic scarlatina: A medical man, aged 24, had already suffered from measles and whooping-cough. In the course of his medical training he had frequently been in contact with cases of scarlatina, and for the preceding two months he had helped the author almost daily in his scarlatina department. On November 15th the patient injured the ball of his right thumb, the skin of which was slightly abraded. On the evening of the same day he assisted in examining fresh cases of scarlatina. Next day the right hand was painful, and the abrasion on the thumb was slightly reddened and tender, but not swollen. On the third day a bright red line, 3 cm. broad, could be seen running from the abrasion along the flexor aspect of the forearm, up to the elbow. The evening temperature was 39.2°C., the pulse 118 to 132. He vomited frequently, was very thirsty, and the tongue was dry, but there was no angina faucium. The neck now showed an incipient scarlatinal rash. On the fourth day the rash had extended considerably, and the throat had begun to be sore. Twenty-four hours later the clinical picture of typical scarlatina was complete.

SURGERY.

20. Primary Removal of Projectiles.

STABSAZT PROFESSOR REHN has discussed (Bruns's *Kriegschir.*, Heft, 1917, xxxv, p. 220) gunshot wounds from the point of view of the primary removal of lodged projectiles. While primary removal should never be undertaken in uncomplicated wounds of the thorax, in wounds of the extremities, when produced by fragments of large or medium size, it constituted the standard treatment. On the other hand, in presence of a widely open pneumothorax with laceration of the lung primary removal was desirable, while in cases of multiple grenade wounds

of the extremities and of the superficial soft parts of the body generally no systematic removal should be undertaken, as the small fragments either become encapsulated or readily discharged if suppuration occurred around them. Operation on the abdominal cavity was never performed solely with a view to removing the projectile. The time for operating must largely be determined by external circumstances, but removal of a lodged projectile should be carried out in the primary stage whenever possible, since operative measures were frequently useless after the lapse of a few days. Operation in the intermediate stage, which commenced about thirty-six hours after wounding, was especially to be avoided. During this period there occurred a renewed bacterial invasion and greatly increased vulnerability of the tissues, most distinctly marked in wounds of the head, but no less dangerous in those of the extremities and body cavities. *Brain*: Expectant treatment was as a rule adopted, even where the foreign body had been precisely localized. In specially favourable conditions, when the fragment was of such size and in such position as to be easily reached, and was of a kind suitable for the use of the magnet, extraction was permissible in the primary stage. In the intermediate stage, all intervention not imperatively called for was avoided, any additional injury inflicted in this stage being liable to be followed by rapid spread of the infection to the vital centres or ventricles, or, in more superficial injuries, by extensive prolapse. The rule, therefore, was that removal of the projectile in the primary stage was permissible in certain conditions, but inadmissible in the intermediate stage. *Abdomen*: In penetrating wounds of the peritoneum, with wound of the viscera, operation was directed to the injuries inflicted rather than the removal of the projectile. The preliminary localization of the latter was therefore omitted, since it increased the depression of the patient. Moreover, it was unwise to place too much reliance on indications derived from the x rays, for wounds which appeared to be purely superficial often proved to be accompanied with contusion of the viscera, perforation of the peritoneum, and subcutaneous prolapse through small peritoneal wounds. Penetrating wounds of the abdomen were preferably treated at the main dressing station, reinforced with a small operating section from the Feldlazarett. The erroneous view was still held by some surgeons that it mattered little whether an abdominal case was transported five or fifteen miles, the delay in operating being but trifling. The time of operating was, however, of small importance compared with the depression in the patient's condition resulting from prolongation of the transport. Operation was not undertaken during the period of shock, nor immediately on the improvement in the patient's condition which followed the use of stimulants and intravenous injection: unless this improvement persisted for several hours, time, which could be devoted to other patients, was not wasted on the case. Except where the peritoneum was extensively contaminated with faeces, irrigation was restricted as much as possible, especially when evidences of localization of the inflammatory process existed; unnecessary displacement of the viscera was avoided. Clinical indications often served as a guide to the internal injuries, but in the absence of these no prolonged search for the projectile was made, for as a rule it was readily found in all cases where its removal was possible. By a strict adherence to these details Rehn succeeded in reducing the mortality in abdominal wounds with lodged projectiles to 50 per cent. *Extraperitoneal wound of the large intestine* was suitable for primary operation, but this was often impracticable owing to difficulties in diagnosis, except when a primary faecal fistula was present. Primary removal was also performed in extraperitoneal wounds involving the bones of the pelvis. Delay in operating in these cases beyond the first twenty-four to thirty-six hours exposed the patient to general infection from the loose cellular tissue of the pelvis. *Thorax*: In the primary stage expectant treatment was, as a rule, adopted, and in uncomplicated cases operation was restricted to aspiration, even in presence of severe infected haematoma, until adhesions had securely fixed the lung and isolated the effusion and pulmonary wound—that is, until the nineteenth day. This rule was necessarily discarded in cases complicated with grave haemorrhage (lungs, heart, great vessels) or open pneumothorax. The customary treatment of open pneumothorax was to open up the pleural cavity widely. But this course was followed by numerous failures attributable mainly to three causes: (1) Loosening of the sutures between lung and chest wall, with consequent incurable secondary pneumothorax; (2) death from the third to the fifth day, with signs of commencing general

infection; or failure to rally after the operation, due to traction on the hilum of the lung caused by the lung fixation; (3) the shock of the operation superadded to that of the injury and subsequent transport. Rehn based his treatment on a consideration of these facts. Wide opening up of the pleural cavity was adopted only where severe haemorrhage was present or the chest wall had been extensively ripped up by the injury, and in such cases alone was an attempt made at primary removal of the projectile. The danger of dragging on the hilum of the lung was avoided by the use of percutaneous sutures for lung fixation; this had the additional advantage of bringing large areas of the pleural surfaces evenly into contact. The sutures were placed in the third or fourth intercostal space anteriorly, laterally in the fourth or fifth, and posteriorly in the fifth, and were left in for eight days. Open pneumothorax without great loss of substance in the chest wall received purely expectant treatment, the patient being placed in a suitable position and excision of the wound being dispensed with. Percutaneous fixation of the lung was performed in such cases when there was severe infection of the wound, in view of the possibility of secondary pneumothorax arising. Cases of open pneumothorax somewhat severer than these were treated by excision and primary suture of the wound with lung fixation as above described. For expanding the lung in these cases careful aspiration of the pleural contents was preferable to the use of pressure apparatus. Rehn reckoned the intermediate stage in wounds of the thorax as extending from the second to the nineteenth day. In this stage treatment was as far as possible expectant. Apart from severe secondary haemorrhage the only condition that could give rise to doubt as to the line of treatment was acute empyema. This condition, complicating an even temporary pneumothorax, was much graver than the ordinary infected haemothorax, and if neglected might be succeeded by a rapidly fatal general infection. In spite, therefore, of the danger from secondary open pneumothorax and post-operative general infection which operation in the intermediate stage involved, rib resection was performed if the case appeared to be urgent. The resection was carried out after the fourth day, when the empyema might be considered to have become localized. In the secondary stage conditions were favourable for the removal of a lodged projectile. Rehn deferred the description of the method to be employed, merely stating that he was in favour of early removal, at the same time giving a warning that it could not be successfully undertaken in the absence of clear indications, and an appreciation of the difficulties to be encountered.

21. Treatment of Abdominal Wounds.

R. BASTIANELLI has furnished a report (*Polieclinico*, February 11th, 1917) on 277 cases of abdominal wound treated in a third surgical unit of the Italian army between June and November, 1916. Fifty-four cases were non-penetrating; of these two died from infection of the abdominal wall. In some of the penetrating wounds the aperture of entry was in the thigh, in others in the upper intercostal spaces, in others again in the buttock. In the 223 cases of penetrating wound, recovery took place in 76 (34 per cent.). Operation was performed upon 140 cases, with 61 recoveries (about 43.5 per cent.); among these there were 12 without any visceral lesion, although in some the bullet had gone right through. In 83 no operation was done, and in 15 (19 per cent.) of these recovery took place. In none of these was there a lesion of the gastro intestinal canal, and in 3 there was no visceral lesion, the projectile being seen free in the belly, and causing no abdominal symptoms. Of 128 patients operated on for visceral lesion 50 (39 per cent.) recovered. Of the 80 not operated on 12 (15 per cent.) recovered, and of these none had lesions of solid viscera. In 108 cases of lesion of the gastro-intestinal canal operation was performed, with 36 (32.4 per cent.) recoveries; 20 cases of wound of other viscera (liver, kidney, spleen, and bladder) were operated on, with 14 (70 per cent.) recoveries. Sometimes even a late intervention has been successful, but Bastianelli is convinced that for many wounds there is a very brief period of time, probably less than one hour, after which infection is incurable. Immediate operation might save cases otherwise inevitably doomed. It is therefore necessary to create advanced stations for laparotomy close to the fighting line. Referring to post-operative complications, Bastianelli points out that sepsis of parietal wounds may be produced by the surgeon as well as by the missile. Incomplete suture and plugging of the wound did not always suffice to prevent it. He limited his incisions, except in case of necessity, to the middle line and the outer border of the rectus, so as to avoid complex

muscular wounds in which necrosing and gaseous infections readily develop. He endeavoured to protect the laparotomy wound and to disinfect it almost continuously during the operation by means of Dakin's or Giannettasio's solution, but with uncertain results. Bastianelli believes that infection of the abdominal wall is caused by inoculation during the operation, and also afterwards by a microbic invasion which passes from the peritoneum through the stitch of the serous coat. This peritoneal infection is present in varying degree shortly after the injury, and the fate of the wounded man depends on whether it develops or not. The mechanical work of the surgeon only prevents a later pouring in of infective and toxic material, but can do nothing against that which has already taken place. The author seldom used lavage of the peritoneum; more often he employed drainage or plugging, but without obtaining decisive advantages.

22. The Alternating Use of Antiseptics.

CHARLES RICHET holds on theoretical grounds that a surgeon should never use a particular antiseptic solution for two consecutive days in the treatment of a wound (*C. R. de l'Acad. des Sciences*, 1916, p. 589). He showed in 1914 (*ibid.*, clviii, p. 764) that microbic organisms (the lactic ferment) developing in abnormal solutions—that is, those which contain feeble quantities of a toxic body—become accustomed very quickly, sometimes in twenty-four hours, to the unfamiliar substance applied, and Richet believes that when a given antiseptic solution is used for a wound for several weeks the microbes become gradually adapted to it, so that its antiseptic action is notably weakened. A daily change of the antiseptic solution is therefore a rational procedure. He groups antiseptics thus: (a) Oxidizing antiseptics, such as hypochlorites, hypobromites, iodine, chlorine, oxygenated water, ozone, and potassium permanganate; (b) metallic antiseptics—namely, salts of mercury, silver, zinc, copper, iron, etc.; (c) aromatic derivatives, phenols, salicylates, thymol, naphthol, creosote, etc.; (d) diverse antiseptics, such as formol, chloroform, essences, chloral, fluorides, boric acid, etc. He suggests the use of a substance out of groups a, b, c, and d, respectively, on four successive days, followed by a different member of each of these groups on the next four days, and so on. He holds that the great advantage of a daily change of antiseptic solutions is that the microbes which multiply in the wound have each day to strive against a different poison, so that they have no time to acquire tolerance. He thinks the same principle should apply to remedies for internal diseases also. Just as in tuberculosis each new remedy may give a good result for some days, he suggests that the parasites of malaria, syphilis, or typhoid fever, may possibly acquire a tolerance of drugs taken by the mouth.

23. Effects of Malaria on Wounds.

VANDENBOSCHE, in a thesis presented to the University of Lyons (abstracted in the *Journ. de méd. et de chir. prat.*, April 25th, 1917), records his observations at Salonica of the effects of malaria on wounds. In patients who have suffered from malaria even slight wounds may bring on an attack of fever. Operation may have the same effect, the attack coming on from one to six days afterwards. The effect is more constant when general anaesthesia is employed, and the anaesthetic may of itself bring on an attack. In tropical countries chloroform has a specially injurious action on the liver, and as that organ is very often affected in malarial subjects the frequency of post-chloroform jaundice in such people is explained; ether, which is less toxic, should therefore be used. In intensely malarious regions the latent paludism is all the more dangerous, since in those districts persons having all the appearance of health may carry the parasites in their blood without ever having had any manifestations of the disease. In the hospitals at Salonica the most diverse haemorrhagic phenomena were observed in old-standing malarious patients. Some suffered from epistaxis, which was occasionally fatal; others had haemoptysis or haematuria; others came covered with petechial and ecchymotic patches. Every malaria patient must, says the author, be regarded as a "bleeder"; he should therefore be operated on only with the strictest precautions. Malarial attacks, of course, blur the clinical picture produced by a wound or its complications. Unless the possibility of malaria be borne in mind, fever in a wounded man may mislead the most experienced surgeon into enlarging the wound. Vandenbosche further calls attention to malarial gangrene, which is fortunately rare; he also mentions cases in which a malarial attack simulating appendicitis has brought the patient to the operating table.

24. Penetrating Wounds of the Vertebral Column.

EHRENPREIS (*Rev. Neurologique*, November-December, 1916) reports 27 cases of penetrating wounds of the vertebral column, 10 of which were in the cervical, 12 in the dorsal, and 5 in the lumbar region. In 18 cases no operation was done beyond enlargement of the wound, with the usual local and general treatment; of these, 16 died and 2 were evacuated. In more than half the cases death took place before the seventh day, either from multiple serious injuries to the cord or from meningomyelitis. For the prevention of bedsores and bronchopneumonia, which, with vesico-renal infections, were the chief causes of death, the author recommends a bed designed by J. R. Proust; it consists essentially of a framework of wood, on which are stretched straps, which can be shifted as required, so as to avoid too prolonged pressure over one spot. The frame can be raised or lowered by a special mechanism, and the wound is thus easily accessible. In 7 cases operated on there were 5 deaths; one (fracture of the third and fourth cervical vertebrae with the Brown-Séquard syndrome) was completely cured; and one (incomplete division of the cord at the level of the seventh cervical vertebra) was greatly improved. In all the seven cases the operation consisted in a long mid-dorsal incision for the extraction of splinters of bone, fragments of shell, bits of cloth, etc., without any attempt being made to secure union. Ehrenpreis thinks the prognosis of wounds of the cord extremely gloomy. All the surgeon can do is to intervene immediately in the hope of checking the infection, which is the principal cause of death.

25. Syphilis and Appendicitis.

THE importance of the two extremely common chronic and persistent infections, tuberculosis and syphilis, in producing morbid changes not obviously of a specific nature is perhaps sometimes overdone. The late Professor Landouzy, in probably his last published article, pleaded for tuberculosis as the cause of appendicitis, and GÄRCHER (*Bull. Acad. Méd.*, Paris, 1917, 3 sér., lxxvii, pp. 387-389) now brings forward cases in support of his contention that congenital syphilis plays a part in familial appendicitis. In a striking instance there were eight children in a syphilitic family, three died soon after birth and the remaining five had appendicitis. He also quotes a family to show that several cases may occur in the second generation of congenital syphilis. In the discussion on this subject JALAQUIER (*ibid.*, pp. 425-427) quoted 80 cases of appendicitis in which the Wassermann reaction had been applied. Out of 60 children it was negative in 52 and positive in 8, but allowing for the fact that in congenital syphilis the Wassermann reaction may be negative in 5 per cent., the positive figure is corrected to 11; in 20 adults the reaction was positive in 6 and negative in 14. Therefore, as the Wassermann reaction was positive in but 17 out of 80 operative cases of appendicitis, it appears that syphilis and appendicitis may sometimes occur together but are quite independent.

26. Amputation for Trench Foot.

TEMPORARY LIEUT.-COLONEL G. A. WRIGHT (*Journal of the Royal Army Medical Corps*, February, 1917) refers to the question of amputation in men suffering from gangrene due to trench foot. In a number of cases a decision had to be made as to the best procedure when part, or the whole, of a foot was lost, and a large raw surface remained. Where the bones are seen bare and dead on the face of the stump surrounded by an area of granulating, or cicatrized, soft parts, the author thinks the best practice is to remove only those structures obviously dead, although a secondary operation must of necessity be performed later. If any formal operation is done at once, either too much or too little may be taken away. Moreover, any disturbance of wounded tissues in such patients is apt to be followed by an acute septic process. As little as possible should therefore be done until the extent of actual complete destruction is determined, and the patient's general condition is improved by rest and care. Large and irregular scars may, however, remain. In some cases the amount of destruction of soft tissue leaves no choice, and a formal operation at a higher level is called for. It is too soon to say whether the stump left by "trimming" trench feet will be serviceable, but if a useful foot can be preserved, Professor Wright maintains that it is better to keep it than to sacrifice it for the sake of doing a formal operation. He recognizes the hardship inflicted upon the men by repeated operation, and fears that this cannot always be helped in the case of trench feet.

PATHOLOGY.

27. Prolongation of Immunity against Tetanus.

VALLEI and BAZAN (*C. R. de l'Acad. des Sciences*, June 25th, 1917) draw attention to the short duration of passive immunity given by antitetanic serum and to the need for devising a method for prolonging immunization. The method they propose is to immunize by means of tetanus toxin attenuated by iodine, according to Roux's plan. A toxin lethal to guinea-pigs in the strength of one hundred-thousandth of a cubic centimetre to 2.50 grams of body weight was used, and the iodine solution consisted of 1 grain of iodine and 2 grains of potassium iodide in 200 c.cm. of water. Seven black wounded soldiers were treated by injections of the toxin-iodine mixture at intervals of five days. The first injection was 1 c.cm. of a two-thirds toxin and one-third iodine solution; the second injection was 2 c.cm. of the same solution; the third injection was 5 c.cm. of a three-fifths toxin and two-fifths iodine solution. Seven rabbits were treated with the same doses at the same intervals. After ten days the rabbits resisted a 2,000 minimal lethal dose of toxin. Another batch of rabbits treated with one-third of these doses resisted a 200 minimal lethal dose at the end of ten days. The authors point out that for primary injection reliance should be placed on antitoxin, as the immunity from vaccine does not reach its maximum until after ten days. It will be necessary to determine the relative duration of immunity following repeated vaccinations. If the period of immunity proves satisfactory this method should overcome the grave inconveniences of serum rash and serum sickness. Other observers have obtained satisfactory results in the immunization of horses upon the same plan.

28. Ferments in the Cerebro-spinal Fluid.

E. LESCHKE and L. PINCUSOHN (*Deut. med. Woch.*, January 18th, 1917) have found glycolytic and diastatic ferments in the cerebro-spinal fluid. The glycolytic ferment did not survive aspiration for long, and could not be demonstrated in the cerebro-spinal fluid on the third day after lumbar puncture. In four cases of diabetes of moderate severity there was not a trace of this ferment, although the diastatic ferment was found. Small quantities of diastatic ferment were found in the cerebro-spinal fluid of all the healthy persons examined, and also in a great variety of diseases, including tabes, general paralysis, cerebro-spinal and meningeal syphilis, tuberculosis, diabetes, neurasthenia, nephritis, tetanus, and epidemic cerebro-spinal meningitis. The nature of the disease had no apparent effect on the quantity of the diastatic ferment, which was also independent of the cellular contents of the cerebro-spinal fluid.

SKIAGRAPHY.

29. Lateral Skiagraphy of the Spine.

HICKEY (*Amer. Journ. of Roentgenol.*, March, 1917) states that in patients who have suffered traumatism of the spinal column he examines with x rays, not only in the antero-posterior direction, stereoscopically, but also in the lateral direction. He does not consider that the flat plate alone sufficiently accentuates the pathological condition which is so often present. The difficulties in the examination of the spine laterally, which have made many workers content only to take stereoscopic plates in the antero-posterior direction, are due, in the first place, to getting suitable penetration of tube, and, in the second, to the natural exaggeration due to the distance of the examined part from the plate. Recent improvements in tube construction have made it possible to get sufficient penetration to radiate the body satisfactorily from side to side, while distortion can be obviated by increasing the distance between the tube and the patient. One of several cases mentioned illustrates the value of the lateral view. A young medical officer was about to proceed overseas for war service when he met with a railway accident. Physical examination of his back revealed no evidence of injury, although he was examined by some eight or ten medical men. An antero-posterior plate showed a slight change between the eighth and tenth dorsal vertebrae; but a lateral plate showed a very marked example of compression fracture. The author believes that many lesions of the spine which are inconspicuous or almost unobservable on the antero-posterior plate will show on the lateral view a good clear reading.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

War Number.

MEDICINE.

30. "Big Belly" in Soldiers.

DÉSIRÉ DENÉCHAU and HENRY MATTRAIS (*Ann. de méd.*, March-April, 1917) have seen men suffering from abdominal disturbances, mild in themselves but accompanied by symptoms suggestive of serious disease. They describe the condition under the quaint name of "les gros ventres de la guerre." The patient is almost always a soldier sent back from the front complaining of ill-defined functional troubles, such as discomfort after meals, breathlessness on the march, and abdominal distension. These symptoms are often so pronounced as to lead the medical officer astray. Details of nineteen cases are given. The authors describe several types. One patient with a long history of dyspeptic disturbance came with the diagnosis of Pott's disease. The abdomen was excessively prominent, recalling that of a woman seven or eight months pregnant. There was no real projection of the vertebral column, no painful point, no dullness. Radioscopic examination confirmed the absence of organic disease, and the condition was attributed to muscular action. The man, by straightening his spine and flattening his thorax while the pelvis was pushed forward, made his abdomen project by pressure on the viscera. This he could do in the upright position and while on the march by keeping his knees slightly bent. By forcible flexion of the thighs in the recumbent position, the pelvis was made to swing backwards and the abdomen recovered its normal size. With the patient on all fours the same effect was produced, though less completely. In another type the lumbar curve was exaggerated to a degree amounting to lordosis, which disappeared under forced flexion of the thighs. Analysing a further group of cases, the authors note that the only constant symptom was the "big belly," with variable accompanying disturbances—hyperchlorhydria, diarrhoea of colitic type, sometimes aërophagy and sialophagy. In most cases there was faulty position of the pelvis and dorso-lumbar spine, with active contraction of the diaphragm. The abdominal wall showed general relaxation, especially at the level of the oblique and transversalis muscles, and even at the quadratus lumborum. On radioscopic examination, at the moment of relaxation, whether spontaneous or as the result of hyperflexion of the thighs, the diaphragm showed a normal curve and respiratory movements of regular amplitude. The authors think there is no question of simulation in these cases; but there is often exaggeration, and especially auto-suggestion as the sequel of a gastrointestinal affection, which leaves some abdominal discomfort. This, when the patient begins to take food, directs his attention to his digestive apparatus. He begins to suffer from sialo-aërophagy. From this to the auto-suggestion that he is affected with a serious disease of the abdomen is but a step. How is the simple-minded man to convince a sceptical doctor of the reality of these disturbances unless by exaggerating the size of his abdomen, which is the principal seat of his sufferings? Therefore it is with the belly thrust forward, the chest drawn in, the elbows held back, and the hands pressed to the sides of the abdomen, as if it were being carried, that the man presents himself. Diagnosis is based on the contrast between the abdominal enlargement and the slightness of the coexisting general and functional disturbances.

31. The Future of the Trephined Soldier.

THE Société de Neurologie some time ago passed a resolution that, as a general rule, men who had been wounded in the skull should not be sent back to the front; many of them, however, could be employed in the auxiliary services at a distance from the noises of the firing line. At a meeting of the society last October (*Revue Neurologique*, November-December, 1916) A. SOUQUES and J. MÉGEVAND gave details of two soldiers, trephined twelve months before and presenting only subjective symptoms, who were able to do duty fifteen to twenty kilometres behind the firing line. But after being two or three kilometres from the front line during an intense bombardment, continual and severe headache began, with incessant vertigo, mental confusion, and losses of consciousness.

When taken to the rear they soon improved. Jean Camus and Nepper, in a previous communication to the society, had shown by graphic records of respiratory and cardiac rhythms, vasomotor disturbances, and tremor, that there was exaggeration of emotional reactions in trephined men. Souques and Mégevand conclude that trephined men who suffer only from slight and passing subjective disturbances should not as a general rule be discharged, as most of them are capable of doing useful work in the auxiliary services; they may even be utilized at the front provided they are not exposed at close range to violent and prolonged cannonading. Further, they must be kept under medical supervision, so that they can be sent to the rear if necessary. In the discussion A. Charpentier pointed out that the prognosis of cranial wounds is always much more serious when the dura mater has been opened.

32.—MARTIMOR investigated the question whether in the *petits trépanés*—that is, men who after trephining show only slight nervous sequelae—there is any mental change likely to affect their future. The results are given in a thesis presented to the University of Lyons and analysed in the *Journal de Médecine et de Chirurgie* of May 10th, 1917. The method employed was to test the mental functions—memory, association, judgement, attention—on a standard plan so that patients could be compared in regard to the quality and rapidity of their intellectual operations. Investigation of 40 cases showed that it is quite exceptional for men with skull wounds to manifest any serious mental disturbance; in particular, Martimor never saw a case of the general pseudo-paralysis described by other observers; nevertheless, almost all skull wounds produce psychical changes. Clinically, these mental sequelae are almost identical; they consist essentially in slowing of the intellectual processes with increase of emotivity and liability to fatigue. In certain cases the responses to the tests were more defective and the changes of temper more marked a year after the wound than they were after six months. A much longer experience is required for certainty in prognosis, but Martimor draws the provisional conclusion that soldiers so injured should be discharged from the army or placed in an auxiliary service. The present tendency is to do this. Even if the danger of motor, labyrinthine, or convulsive disturbances did not exist, the mental state of many men with skull wounds would warrant their being kept away from the front. So emotional are they that the slightest defonation produces disturbance out of all proportion to the cause, with transient inhibition of the mental functions and of will power.

33. "Captivitis."

PROFESSOR CH. JULLIARD of Geneva (*Rev. méd. de la Suisse Romande*, July, 1917) describes a peculiar mental state observed in prisoners of war. The Germans call it "barbed wire psychosis." During an inspection of seriously wounded men in France by the Swiss repatriation committee he saw a case which presented close analogies to accidents in workmen. This suggested to him that under the influence of captivity a mental state might be produced similar to that described by Brissaud. For this condition he proposes the term "captivitis." The patient was an Austrian civilian prisoner, aged about 40, who was under treatment in a military hospital for various symptoms. He had been examined several times by the committee, which arrived at no definite decision. The man, who kept his bed, complained of vague pains in the chest with difficulty of breathing and headache. His urine was loaded with phosphates. The pains, which flitted about from one region to another, were of a nature likely to induce the committee to recognize the case as one suitable for repatriation. A minute examination, confirmed by the careful and prolonged observation of the doctor under whose care he was, showed no objective lesion except slight chronic bronchitis and emphysema. The man was extremely voluble in the endeavour to persuade the committee of the gravity of his condition. Repatriation was a fixed idea. A true psychosis could be excluded. Julliard, however, thought the diagnosis of simulation might be put aside, as, in spite of all that seemed to suggest it, the man struck

him as being in good faith. On the other hand, auto-suggestion was evident. As in labour accidents, the origin of the mental state was an erroneous idea of compensation. This notion was kept up, as in accident cases, by the careful treatment given him and repeated examinations by a number of doctors. As no decision was come to, recovery was delayed for months and no treatment was of use. Repatriation could not be advised, as the committee was convinced that the so-called disease would disappear with the cessation of the captivity. Nor could there be any question of punishment, as there was no simulation. Continuance of treatment would merely fix the false idea more deeply in the man's mind. The only solution of the problem seems to be to remove all hope by informing him that he was not considered a case justifying repatriation and that he must be placed in a concentration camp. Julliard suggests the presence in such cases of a kind of "mental foreign body," a fixed idea, producing certain psychical reactions.

34. Artificial Oedema of Limbs.

MÉRIEL (*Paris méd.*, June 30th, 1917) calls attention to an elephantiasis-like oedema of the limbs following slight wounds (small shell fragments, burns of the second degree, superficial contusions, incomplete fractures of radius and fibula). The infiltration is larger and more durable than that seen after similar injuries in civil practice; and owing to the condition many men have been discharged as permanently unfit. Cases having recently come in greater numbers before medical boards, Mériel became suspicious, and discovered that the oedema was generally the result of constriction for many days consecutively by a piece of string or cloth. The artificial origin of the oedema was proved by its disappearance under a plaster bandage left in position for a fortnight. In some cases the artificial oedema when recent is slight and curable; more often, when the constriction has been kept up, trophic lesions are produced which become permanent or take a very long time to disappear. The lesion is a more or less considerable oedema, always segmental, on the hand or foot, going upwards to the forearm or the leg, variable in consistence, sometimes hard but most frequently soft, pitting on pressure; the skin is glossy, thin, cold, sometimes bluish, sometimes white. The swelling, whatever be its upper limit, is always bounded by a well-defined cushion, beyond which the tissues are perfectly healthy. There is great impairment of movement of the fingers. They are thick and sausage-like, or are kept apart by enormous lymphatic infiltration, which after a time causes trophic lesions due to neuritis. Sometimes there is segmental anaesthesia; sometimes sensation is normal, or there may be slight hyperaesthesia. Apart from the clinical signs of various sensory disturbances a proof of these neuritic lesions is furnished by the x ray, which reveals well-marked decalcification of the bones of the hand and foot. But while neuritis is indisputable, it is secondary and not primary. This, according to Mériel, proves that the oedema is not due to neuritis following nerve injury, but that it is oedematous infiltration caused by induced vascular lesion causing the neuritis. The neuritis does not retrocede like the oedema; it persists much longer, and in time inevitably produces the disability desired by the patient.

SURGERY.

35. Rocket Pistol Wounds.

AMONG the rarer varieties of shot wounds must be reckoned those due to the discharge of pistols used, in the trenches and elsewhere, for the firing of rockets either as signals or for the purpose of lighting up enemy lines at night. W. KESSLER (*Volkman's Samml. klin. Vorträge*, No. 729; *Chir.*, No. 199, 1917) comments on the scantiness of the literature of these cases, and describes in full detail an instance coming under his own observation. Brief notes of ten others are added, and reference is made to nineteen more reported from the German navy. The rocket pistol is described as having a bore of about an inch, with a fairly short barrel. The rocket takes the form of a cartridge, made of zinc in the case of star lights or light rockets, and closed with a cork. Kessler describes various lesions that may result in cases of injury by the discharge of such pistols and cartridges. Burning of the tissues is usually the most prominent feature, as the special composition of which the combustible mass of the rocket is formed contains its own supply of oxygen, and so gives rise to flames and heat that cannot readily be quenched. If the patient is wounded at short range, fragments of the rocket casing may act as projectiles, and burning portions of the rocket may be blown

into the tissues and generate gases that will act on the tissues as poisons. At very short range the firing of the explosive charge in the cartridge behind the rocket will also have a burning and toxic effect on the injured tissues. All these features were observed in the case seen and reported by Kessler himself. The man received the discharge of a rocket pistol in the region of the right buttock at very short range. Two hours later, when seen at the field dressing station, he was unconscious, with clenched jaws, foam at the mouth, and a slightly irregular but full pulse beating 160 to the minute. There was a burn of the second and third degree in the mesial and lower part of the right buttock and upper and inner part of the right thigh, with a wound 3 cm. long in that part of the buttock. There was extensive surgical emphysema, most conspicuous on the left side of the back and the right thigh, extending up to the xiphoid process in front. The wound was dirty, and was laid freely open; the tissues were seen to be much altered in appearance; the muscles looked pale and dull, as if cooked and dry, and the muscular bundles had separated from one another. The patient was twice bled, and oxygen inhalations were given; he did not regain consciousness, but became very restless and morphia was given. About twenty incisions, each an inch long, were next made for the relief of the surgical emphysema, and perforated drainage tubes a foot in length were carried through between each pair of incisions, some twelve hours after the original injury had been received. Signs of gangrene appeared in both lower extremities and there was evidence of oedema of both lungs within a few hours; these phenomena were attributed by the medical consultant to embolism. The patient died within twenty-four hours, with shallowing respiration and weakening pulse. At the autopsy about twelve hours later rigor mortis was present, with pallor, cyanosis of the ears, considerable reddish-blue post-mortem staining, and a dark cyanotic discoloration of the scrotum. The surgical emphysema was absent in the region of the incisions made for its relief; fragments of foreign bodies were found in the neighbourhood of the enlarged wound in the right thigh; the skin and subcutaneous tissue had been stripped up and separated from the subjacent fascia by gas generated in the wound by the rocket, and were greyish-green in colour. Considerable separation of the tissues in the neighbourhood of the wound in the right thigh had taken place. Spectroscopic examination of blood taken from the patient during life showed the presence of carbon monoxide, and Kessler notes that a peculiar sweetish smell developed in the operating theatre while the patient was first being examined and bled; so much so, indeed, that the operating surgeon and his assistant were suddenly overtaken with feelings of anxiety, nausea, and a desire for fresh air, and had to sit down. They felt an inability to use the thoracic respiratory muscles that lasted twenty minutes, and for more than an hour had weakness in the knees, headache, and nausea. Kessler comes to the rather surprising conclusion that the cause of death in this severely burned, shocked, embolized, and gangrenous patient was carbon monoxide poisoning. It appears that the mortality of rocket pistol wounds is high; death occurred in 8 out of the 30 cases he mentions. In one instance the cork disc with which the rocket cartridge is closed was blown into the femur, lodging in the medulla of the bone. In another case a lieutenant suddenly saw a red cloud fly down on to his left knee. This proved to be a light-ball, and it produced a burn the size of a hand, in the middle of which was a hole the size of half a crown leading down to the calf, opening up the knee joint and dissecting out the muscles, and lined with slimy masses and metallic particles. The wound was opened up freely and cleaned, and after four months of treatment only a small granulating wound was left. A curious distribution of the cutaneous lesion resulting from the discharge of these pistols is recorded in two instances occurring in the navy. In one the central burn, 3 to 4 cm. in diameter and red and green in colour, was surrounded by a pale yellow ring 3 cm. wide, and this in turn was surrounded by a dark blue ring 2 to 5 cm. in width. In the other a central area of uninjured skin 1 cm. across was invested by a ring of blackened skin 1 cm. wide limited by an annular split in the skin; outside this was a ring of unaltered skin $1\frac{1}{2}$ cm. in width, and outside this again was a zone of burnt and blackened skin 2 cm. wide.

36. Paralysis of Peripheral Nerves in War Wounds.

E. DUROUX, in a paper abstracted in the *Revue Neurologique*, November-December, 1916, summarizes his observations on the various kinds of paralysis of peripheral nerves resulting from wounds. Under the head of

paralysis due to division of the nerves he says the incidence of true section is not more than 10 per cent. For the re-establishment of continuity between periphery and centre the surgeon has several methods at his disposal. Suture has given the author good results. He also employs neuroplasty. Nerve grafts are necessary when the loss of substance is considerable. The prognosis of paralysis due to section appears to depend on the method of intervention. It is better to operate before trophic and articular disorders become irremediable. In this way very rapid restoration of sensibility is sometimes secured, though this is exceptional in regard to motility. The trophic processes are greatly influenced by the restoration of a nerve, and cyanosis, ulceration of the skin, and changes in the nails often disappear before any sign of return of movement. Speaking generally, a year is required for a "satisfactory" recovery of motor power and two for complete restoration. In paralysis due to embedding in scar tissue good results are obtained by clearing the cicatricial focus, toilet of the nerve and immobilization in healthy tissue, or protection by a graft. Failure is due to changes in the nerve. If it is evidently destroyed at the point of burial in scar tissue, section followed by suture will give the best results. Paralysis is sometimes caused by neuroma; here there can be no question of resection, and intraneural neurolysis is indicated; longitudinal clefts must be made in the nerve so as to allow of extirpation of the cicatricial tissue running into healthy tissue. The author also discusses paralysis due to compression by aneurysm or fracture.

37. Gunshot Wounds of the Chest.

COLONEL A. B. SOLTAU and CAPTAIN J. B. ALEXANDER contribute to the *Journal of Quarterly Medicine* (July, 1917) an interesting paper on 139 cases of gunshot wound of the chest as seen at a base hospital in France. They discuss in some detail the three main conditions which may occur, either singly or in association, in penetrating wounds of the lung—namely, haemorrhage, pneumothorax, and collapse. Haemorrhage was comparatively common, and its size varied within wide limits, but the amount of blood bore little relation to the severity of the wound. In their quest for the factor determining the limitations of size of haemorrhage the authors formed the view that beyond the mechanical haemostatic effect of pressure of the effusion there is a condition of active collapse—either massive collapse or partial deflation—of a protective nature, tending to control haemorrhage. With regard to clotting of the haemorrhage, observation of this series of cases suggested that a partial clotting or at least a deposition of fibrin is constant, but that a true massive clot is extremely rare. Pneumothorax was less common than haemorrhage in this series—thirteen cases being observed as against eighty. An important distinction is drawn between early and late pneumothorax. In the former there is air in the pleural cavity; in the latter there is nearly always gas from a gas-producing organism. The former seldom gave rise to anxiety, while the latter was, of course, a very grave complication. Surgical emphysema occurred in 15 per cent. of the series; it caused little trouble, and soon vanished. Of collapse all stages were seen up to massive collapse. As many as 48 per cent. of the cases showed deflation in some degree, often closely simulating the physical signs of fluid, at other times resembling pneumonic consolidation. A condition to which the authors draw attention is contralateral collapse, frequently observed by them in the undamaged lung associated with collapse of the injured lung. Twenty-four examples were noted in the series, but the causation remains obscure; in the absence of other evidence the suggestion is made that the condition might be due to reflex nervous action.

PATHOLOGY.

38. Cicatrization of Injured Nerves.

A. PITRES, in a paper summarized in the *Revue Neurologique* for November-December, 1916, gives the results of histological investigations of the processes which follow division of a nerve in the connective elements and in the nerve fibre. In the former there is rapid cicatrization by the formation of a collar or band; if the wound is infected a vicious cicatrix is produced which may hinder or prevent regeneration of the nerve fibres. The nerve fibre after passing through the phase of Wallerian degeneration may take the direction of definitive atrophy, or more frequently it may proceed towards structural and functional regeneration. Numerous neuro-fibrillar filaments become detached from the axis-cylinder of the central end, and traverse the cicatricial connective tissues to lose themselves in the peripheral segment where they grow inside the old

sheaths, becoming covered with a coating of myelin; at the same time reabsorption of cellular elements which had accumulated in Schwann's sheath takes place. When this process is complete in the whole of the nerve, signs of functional recovery begin to appear, the voluntary movements being the first to return. Pitres concludes that connective cicatrization is absolutely different from nervous restoration; it only re-establishes the physical, not the functional, continuity of the nerve. He lays stress on the advantage of rapid and aseptic cicatrization in facilitating nerve regeneration. The notion that immediate or very rapid restoration of function in a divided nerve can sometimes be obtained is ill founded. Late suture seldom gives good results; *a fortiori*, resection is absolutely contraindicated.

39. Late Sequels of Skull Wounds.

IN a communication to the *Réunion méd.-chir. de la 1^{re} Armée*, DUPLANT (*Revue Neurologique*, November-December, 1916) related a case in which meningococcal abscess of the brain and cerebro-spinal meningitis supervened twenty months after the date of a wound of the skull. The patient was a soldier who was wounded by a projectile in the retro-mastoid region in 1914; he appeared to be completely cured and had returned to duty. In the early summer of 1916 he began to suffer from headache and vomiting. On admission to hospital clouding of the mind and Kernig's sign were noted; there was hypertension of the cerebro-spinal fluid, which contained meningococci. These micro-organisms were also found in the rhino-pharyngeal exudates. Improvement was brought about by intraspinal injections of meningococcal serum, and eventually the fluid became clear and sterile. Nevertheless the mind continued clouded. The urine contained 40 grams of sugar to the litre, the glycosuria doubtless being of bulbar origin. On June 11th coma supervened and the man died. On *post-mortem* examination there was found infection of the liver, with old subpleural pulmonary granulations; the cerebro-spinal fluid was cloudy, and there was meningitis, particularly marked at the base. There was a large abscess of the occipital lobe communicating with the posterior cornu of the lateral ventricle. There was a large inflamed exostosis of the retro-mastoid part of the temporal and pachymeningitis in that region. On the outer table the periosteum was intact and completely cicatrized. On scraping it two bits of lead the size of a glass pin's head were found. The pus contained an abundance of meningococci and some streptococci. Summing up, Duplant points out that this old wound of the skull, which had caused a tiny lesion of the external table, had given rise to an exostosis of the internal table with late infection. The abscess was due to the localization of the meningococcus at a point of low resistance in the course of a cerebro-spinal meningitis. This got well, but the abscess caused death. A guarded prognosis should therefore be given as to the remote issue of skull wounds, even when the lesions appear to be trifling.

40. Labyrinthine Concussion.

PRENANT and CASTEL (*Paris méd.*, March 10th, 1917) have investigated experimentally the effects of the detonations of explosives on rabbits and guinea-pigs. When deafness was produced by near exposure to gunfire the middle ear was, as a rule, uninjured. The Bárány test gave negative results in ten cases. On *post-mortem* examination no effusion was found in the middle ear or brain. The most frequent lesion was dislocation of the cochlea, particularly in the first and second spiral turn. The organ of Corti was often much damaged and evidence of considerable recent haemorrhage was often seen, with apparent atrophy of the cells, in the first few spiral turns. The cells of the spiral ganglion of Rosenthal were shrunken; in one case there was ascending degeneration of the cochlear nerve. The vestibular organs never showed any trace of injury. The authors conclude that the gravity of war deafness is due to damage to the cochlea.

41. Coincidence of Infectiousness with a Positive Wassermann Reaction.

J. TRINCHESE (*Deut. med. Woch.*, January 11th, 1917) points out that many authorities have maintained that, provided a symptom-free patient has been treated for syphilis sufficiently long and vigorously, a positive Wassermann reaction is not adequate proof, *per se*, of infectiousness. In support of his argument that this view is incorrect, he gives details of six patients who had infected their wives and begotten syphilitic offspring, three to five years after contracting syphilis. They had been "adequately" treated, and were symptom-free. One of his patients contracted syphilis at the age of 25. He underwent four courses of injections (presumably of mercury),

and every symptom, except slight swelling of the inguinal glands, soon vanished. Eight years after infection Wassermann's reaction was still markedly positive, and the patient accordingly underwent a course of inoculation before getting married with the consent of his medical attendant. Eleven months later a healthy child was born, and Wassermann's reaction was negative, both for mother and child. Two years later another healthy child was born, and again the reaction was negative for mother and child. Ten months after the birth of this child—that is, about twelve years after the original infection—the mother developed a typical roseola, and the reaction was definitely positive, as it was positive also in the husband, although he showed no other sign of his old infection.

OPHTHALMOLOGY.

42. Sympathetic Ophthalmia in War.

L. WEEKERS (*Arch. méd. Belges*, March, 1917) notes the extreme rarity of sympathetic ophthalmia in the present war, notwithstanding the great frequency of wounds of the eye. Among more than eight hundred cases of such wounds he himself has not seen a single instance of sympathetic ophthalmia. This fact is not in harmony with the statistics of previous wars; in 1870, for example, sympathetic ophthalmia occurred in 55 per cent. of wounds of the eye; while it is generally agreed that in time of peace this complication is relatively frequent. In the surgical records of the present war Weekers has found only one case in the French army (Valude, *Ann. d'oculistique*, 1916, p. 89). On the German side only a few have been reported. Apart from these cases all the surgeons in the enemy armies who have recorded their experience mention the absence of sympathetic ophthalmia in eye wounds. The cause of this rarity was incidentally discussed at a meeting of the Paris Société d'Ophthalmologie in April, 1916, when Morax expressed the opinion that it was due particularly to the early performance of enucleation. De Lapersonne attributed it to the same cause, but especially to more efficient antisepsis. Poulard thought total enucleation should be replaced by partial removal. Kalt believed that exenteration alone was sufficient to prevent panophthalmia, an affection which moreover involved no danger to the other eye. Published statistics as to the frequency of sympathetic ophthalmia present wide divergencies. The principal cause of this, according to Weekers, is the confusion which has long existed between sympathetic inflammation properly so called and sympathetic irritation. The symptoms of the latter condition are entirely different from those of iridocyclitis or true sympathetic uveitis; the two things have nothing in common, notably in respect of pathogeny. When all cases of typical inflammation, characterized particularly by uveitis giving rise most often to exudation in the anterior chamber, are excluded from statistics of sympathetic ophthalmia, it will be noted that the figures indicating the frequency of that affection are considerably reduced. Most observations record only functional disturbance. In only 17.9 per cent. of the cases do the German statistics for 1870 indicate the existence of organic lesions, and of most of these it can be argued that they were not examples of sympathetic ophthalmia; the lesions were optic atrophy, detachment of the retina, bulbar injection with opacity of the cornea, and so forth. In short, of all the cases recorded under the head of "sympathetic ophthalmia" in those statistics there was not one presenting the characters of a typical sympathetic uveitis. Weekers, however, does not deny the reality of sympathetic ophthalmia, which may supervene even when every precaution has been taken to avoid it; but it is so rare as to be a curiosity. It was more frequent formerly than now, and it is time to discard the fears which were then justified. The diminution in frequency is primarily due to the more rigorous observance of the precepts of asepsis and antisepsis in the treatment from first to last. Removal of the injured eye, even when it is destroyed from the functional point of view, is not justified as a prophylactic measure against sympathetic ophthalmia. By temporizing it is often possible to save eyes which at first appear doomed to enucleation. The surgeon should in this respect be as conservative as possible, whilst bearing in mind that it is better in a doubtful case to remove an eye in which vision is lost than to expose the patient to sympathetic ophthalmia even when the risk of this complication is of the slightest. When ablation is necessary, preference should be given to exenteration, which offers as good guarantees against sympathetic ophthalmia as enucleation, and gives better aesthetic and prosthetic results.

THERAPEUTICS.

43. Chloroform in the Re-education of Functional Deaf-mutes.

In a paper abstracted in the *Revue Neurologique* for November-December, 1916, A. J. RAYNEAU and ANDRÉ BOUTET discuss the inhalation of chloroform in the cure of functional deaf-mutes. The patients may recover spontaneously after the first whiffs of the anaesthetic or immediately on awakening. Recovery may occur later, for instance after twenty-four hours, the cure taking place in two stages—one in which a very slight result follows the administration, a second more remote in which recovery is completed. In some cases spontaneous recovery is never quite complete, the patients remaining for a short time partially deaf, more on one side than the other, with a stammer which disappears after a few days of re-education. The authors had the ears of all their patients examined by specialists, and in every case the drumhead was reddened and depressed; if the lesion was unilateral, hearing was only partially restored on that side, whereas the use of the other ear was fully regained more rapidly. It would seem, therefore, that in all these cases there is an organic and functional association, the organic lesion being in itself quite insufficient to cause the serious disturbances noted, while quite capable of producing secondary functional disturbances.

44. Local Injections of Alcohol in Neuritis.

J. A. SICARD (*Revue Neurologique*, November-December, 1916) has tried the injection of alcohol into the affected nerve trunks for painful conditions left by war wounds. The results of a year's experience encourage him to recommend the method. The technique consists in injecting 1 to 2 c.cm. of alcohol at 60° C.—or 80° C. if the pain is of old standing—into the exposed nerve, at least 3 centimetres above the lesion; the injection should also be made into all the tributary branches within the painful area. As alcohol paralyses both the motor and the sensory fibres, the treatment is applicable only when the pain is so sharp and continuous that the patient clamours for intervention of any kind, even amputation. Motor paralysis caused by alcoholization of the nerve is of little importance when there are grave nervous lesions which have already induced almost complete sensori-motor paralyses.

SKIAGRAPHY.

45. Stereoscopic Radiography of the Limbs.

GAGE (*Arch. Radiol. and Electrother.*, June, 1917) suggests a simplified method of stereoscopic radiography for the examination of fractures to determine the position of the fragments and the presence of sequestra, their number, position, and relationship to sinuses. It is often desirable to obtain first a radiographic image of the skin by careful bandaging with gauze that has been smeared with zinc oxide or mercuric ointment, or impregnated with nitrate of silver or collargol. Smearing the skin with metallic ointment has also been found effective. A small metallic object may be used to mark the sinus, and an indicator should be placed upon the anterior surface of the limb. A plate is now taken, half of which is placed under the limb in the usual position with the film towards the tube, while the other half of the plate is covered by sheet lead. The tube is centred over the whole limb and afterwards displaced 3 cm. laterally. After the first exposure the plate is carefully withdrawn without disturbing the limb, and the unexposed half of the plate inserted, this time with the glass side towards the tube. The second exposure is then made after the tube has again been displaced 3 cm. on the opposite side of the centre. The best stereoscopic results are obtained by increasing the displacement for a thin limb, like the forearm or hand, to as much as 4 cm. on either side of the centre; while for the thigh the displacement should be diminished. The height of the tube also has some influence upon the stereoscopic effect; the closer the tube is to the plate the less displacement is required. To view these plates two mirrors, some 8 in. by 10 in. in size, are placed back to back and bound with a piece of adhesive tape. The mirror should be placed in the centre of the two pictures, and the observer should close an eye until he sees one picture clearly reflected; on opening the eye, a stereoscopic projection of the contour of the limb, rendered visible by the application of the metal-impregnated bandage, is seen, as also is the position of the sinus (marked by the metal disc) and the sequestra, which stand out in their relationship to the sinus, the bone, and the skin.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

46. The Nervous Symptoms in Polycythaemia Vera.

IT is important to insist on the nervous manifestations in the disorder variously called polycythaemia vera, splenomegalic or myelopathic polycythaemia, erythraemia, Vaquez's or Osler's disease, as otherwise they may be regarded as due to an organic brain lesion, and even lead to an operation for cerebral tumour. Although a characteristic case is unlikely to escape recognition, the patients are not necessarily cyanosed or abnormally red; out of ten cases observed by H. A. CHRISTIAN (*Amer. Journ. Med. Sci.*, 1917, cliv), who has recently written on this subject, five when seen at the hospital did not show the cutaneous colour that would suggest the diagnosis of polycythaemia. The patients may, indeed, be pale, and in such instances the nervous symptoms, which are usually the reason why medical advice is sought, may easily be referred to an operable cerebral growth. The nervous symptoms are very frequent. They were noted in all but one of Osler's nine collected cases, and out of Christian's ten cases eight showed definite nervous manifestations, such as headache, dizziness, asthenopia, blurred vision, transient blindness, scotomas often scintillating, diplopia, hemianopsia, slight swelling of the optic disc, paraesthesias, pareses, and paralyses suggesting a focal lesion. One patient was for ten years under neurologists and ophthalmologists, cerebral tumour being often suspected before polycythaemia was recognized, and in another its existence was discovered only after an operation for cerebral decompression had been performed. The blood changes probably exist for a long time before the onset of nervous symptoms, which are at first due to simple circulatory changes, but later depend on cerebral softening, haemorrhage, or thrombosis. There are as yet but few data as to the age at which polycythaemia usually appears, but it is remarkable that Christian's ten cases were all between 45 and 63 years of age, and that eight were between 50 and 56.

47. Malarial Amnesia.

FROM his experience in Beyrout DE BRUX (*Presse méd.*, Paris, 1917, xxv) insists on the frequency of loss of memory as the result of malarial infection, as shown by its presence in nearly a third of the patients under his care in a military hospital there. It is indeed remarkable that so little attention has been paid to this manifestation. It may, however, be easily overlooked, especially when it is unaccompanied by other nervous symptoms. Sometimes it is combined with headache, giddiness, cramps, tremors, formication, and be a prominent symptom of malarial polynuritic psychosis. The occurrence of loss of memory may be considered under the two heads of (1) the febrile paroxysm and of (2) the subsequent periods. During the fever there may be complete loss of memory, so that a complete gap is left. This may involve the events of a few hours and is then permanent and absolute, or the duration of amnesia may be prolonged for weeks and is then less complete, and there may be a transitional stage between the period of good memory and that of more or less complete blankness. After the fever patients may have lost their memory for events before the malarial attack, and this may extend back to childhood, or their loss of memory may affect the events of the recent past and the present, so that the patients are obliged to write everything (notebook sign); there is then considerable loss of maintaining attention.

48. Electrical Tests in Peripheral Nerve Injury.

ADRIAN (*Arch. Radiol. and Electrother.*, May, 1917) discusses the physiological basis of electrical tests in peripheral nerve injury. For prognosis or diagnosis little is to be gained by elaborate testing methods. The presence or absence of excitable nerve fibres can be detected well enough by the ordinary faradic coil; when the nerve has degenerated the faradic current becomes ineffective, and this test is the all-important factor in treatment and prognosis. As to paralysed muscle, faradic and galvanic currents do not give all the information it is possible to

obtain, and here a method based on the use of condensers of different capacities should be able to determine the progress of the muscle after the nerve supply is cut off, and might give useful information as to the effects of treatment; but for deciding whether the nerve has degenerated or not condensers seem to have no advantage over the simple faradic coil. Whether the nerve is growing towards the muscle or is prevented from regenerating by scar tissue is a question for the neurologist and the surgeon; the most elaborate electrical tests can give no answer. Cases of incomplete nerve injury, contusion, compression, and the like are readily distinguished as a rule by neurological tests. In a few cases the nerve is much less excitable below the seat of injury than above it, and when this occurs the response to short currents is more readily obtained by stimulating above the level of the injury. Theoretically it should be possible to measure changes in the conductivity of the nerve fibres not great enough to abolish conduction. Such changes would not necessarily be accompanied by any alteration in excitability except in the immediate neighbourhood of the injury. In isolated muscle nerve preparations a very small change of conductivity can be detected readily enough by measurements of the least interval for muscular summation, with two stimuli separated by a short time interval, but there are considerable difficulties in the way of such estimations in the human subject.

49. Gastric Ulceration in Lymphadenoma.

S. F. REIMANN (*Cleveland Med. Journ.*, 1917, xvi) describes the case of a boy aged 14 years with widespread lymphadenoma of the superficial, mediastinal, and mesenteric glands and of the spleen, in which the walls of the stomach were infiltrated by lymphadenoma and the mucous membrane showed four small circumscribed punched-out ulcers with raised edges. The rest of the alimentary canal was normal. The histological appearances were those of lymphadenoma, though less well marked in the stomach than in the lymphatic glands. There were no gastric symptoms. References are given to four other cases of gastric ulceration in lymphadenoma, the author's case being the youngest.

50. Adrenal Indigestion.

LOEPER, BEUZARD, and WAGNER (*Bull. et mém. Soc. Méd. des Hôp. de Paris*, 1917, 3^e sér., xli) describe under this heading the gastro-intestinal symptoms associated with the slighter forms of adrenal insufficiency. As in Addison's disease, the symptoms depend on atony of the stomach and intestines. Gastric distension, often associated with swallowing of air, comes on half an hour to two hours after food and the HCl is deficient, and constipation is troublesome. Though an associated low blood pressure, melanoderma, and "the white line" (the reverse of the *tachocérébrale*) suggest the underlying cause, the most certain means of diagnosis is the response to hypodermic injection of $\frac{1}{2}$ to 1 mg. of adrenalin once or twice daily. As a result the gastric peristalsis is seen by means of an x-ray examination to become vigorous, and the amount of HCl in the gastric juice is increased, while constipation and the other symptoms diminish.

51. Orchitis of Mumps Complicated by Abscess Due to *B. coli*.

TROUDE (*Bull. et mém. Soc. Méd. des Hôp. de Paris*, 1917, 3^e sér., xli) reports the case of a médecin-major, aged 29, who, fifteen days after seeing some patients with mumps, had fever and painful swelling of the left testis. Two days later the parotids became swollen—an inversion of the usual sequence of events. After a further interval of eight days an abscess in the left testis was opened with evacuation of 8 c.cm. of creamy pus containing *Bacillus coli*, but without any special odour. The wound slowly healed, the testis atrophied and became nodular. The epididymis was not involved in the inflammatory process. Suppuration in the orchitis of mumps is very rare, three cases only being quoted; and as a bacteriological report does not appear to have been previously made, this case is

important as showing that suppuration when it does follow is due to a secondary infection superimposed on that of mumps.

52. Artificial Pemphigus.

At a meeting of the Medico-Chirurgical Society of Bologna (*Policlinico*, June 10th, 1917) F. DE NAPOLI described a number of cases of artificial skin affection simulating pemphigus seen among Italian troops at the front. The site is almost always the legs and the feet, particularly the extensor surfaces; sometimes the arms or face were affected; only once the back. The elementary lesions are bullae resembling those of pemphigus; they vary in size from a hazel nut to a turkey's egg and are generally tense and full of lemon-yellow fluid, in some cases opalescent, never haemorrhagic, rarely purulent. Mingled with the bullae are small vesicles, in some cases confluent, in others disseminated over large patches of papular erythema resembling eczema. The affection lasts a week and mostly ends in complete recovery; in some cases, however, the duration is longer owing to secondary suppuration. In nearly every case the affection appeared in epidemic form among men from the same region. It was discovered that it was produced by the application of a paste made by the trituration of a plant growing abundantly in the territory occupied by the regiments in which the eruption appeared. This plant was identified at the botanical garden of the University of Bologna as *Ranunculus acris*, which, like all the ranunculaceae, has an irritating and blistering action on the skin.

SURGERY.

53. Gunshot Wounds of Kidney.

PATEL (*Paris méd.*, September 29th, 1917), after describing two cases of gunshot wounds of the kidney and hilum, says that wounds of that organ alone are relatively rare. In two years of work in a large hospital at the rear he saw only three cases of old wound of the kidney. Two of the patients had a fragment of shell in the renal pelvis, with clinical signs exactly resembling those of calculus. At the time of the injury there was no sign of serious haemorrhage, only an outflow of liquid, probably urine, through the wound. The surgeons at the front had not thought intervention called for. Patel after localization by radio-scopic removed the fragments by a true pyelotomy; both patients recovered. In the third case a fragment of shell was buried in the renal substance; the man died of infection and secondary haemorrhage before Patel thought of operating. When, as is mostly the case, other organs—intestine, liver, or lung—are seriously injured at the same time lesion of the kidney is likely to escape notice. The diagnosis of renal lesion presents difficulties. The seat of the injury—lumbar or lower thoracic region—is a useful guide. Abundant bleeding through the wound suggests injury to a large vascular trunk, but it is not possible to determine the source more precisely. Haematuria is a sign of capital importance. The absence of all peritoneal reaction in the two cases reported warrants the assumption that the peritoneum had not been touched. As in all cases of war wounds, a precise diagnosis is arrived at by direct exploration of the lesion. In both cases Patel performed nephrectomy, which he considers to be the only possible treatment. The men were admitted in such a condition of anaemia that the immediate arrest of haemorrhage was imperative; in an extensive wound of the kidney plugging would have been inadequate; even if the first gush had been stopped secondary haemorrhage would almost certainly have occurred. In both cases the operation was well borne, and the flow of urine was at once established.

54. Recurrent Tetanus.

AN instance of recurrent tetanus has been recorded by HERMANN MEYER (Bruns's *Kriegschirurg.*, H. xxxix, p. 673, 1917). The patient developed stiffness of the lower jaw twenty-four days after receiving a bullet wound of the right leg. Serum injections were immediately administered, and were repeated on the two following days without producing any obvious effect. On handling the wound, which was discharging freely, twitches occurred in the affected leg, and two days later some rigidity of the back was noticed. On the tenth day, after eight preventive doses and one curative dose of serum had been administered, the symptoms began to decline and the patient made uninterrupted progress towards recovery, except for an attack of severe pain in the leg and thigh,

which occurred on the thirty-seventh day. On the eighty-first day slight trismus recurred, together with twitching of the right leg; two days later twitching occurred in the left leg also, and the abdominal muscles became rigid. These symptoms subsided after a course of serum injections. On the hundred and thirteenth day twitching recurred in the right leg, with marked rigidity of the muscles on attempting to move the limb. These symptoms persisted with little change for five weeks. On the hundred and fifty-fourth day severe and painful spasms occurred in the right leg, back, thorax, and abdominal wall, and there was abundant sweating, with normal temperature. Movements of the arm and jaw were unaffected. At this stage the patient came under Meyer's care; he was then pale and wasted. On the inner aspect of the right leg there was a scar 5 cm. long, and on the outer side a somewhat longer scar, beneath which fluctuation could be detected. Both feet were in a position of extreme equino-varus and immovable; the right knee and hip were flexed, and the whole musculature of the limb rigid. The dorsal and abdominal muscles showed extreme rigidity, but those of the arms and thorax were normal. The masseters became rigid only on opening the mouth widely. The x rays showed the presence of two sequestra beneath the scar on the outer side of the leg. This scar was excised, and an incision into the inner cicatrix opened a cavity, which was lined with granulation tissue and contained opaque serous fluid. From this cavity two sequestra were removed, and mice injected with some of the contents developed the symptoms of tetanus. There was no return of the spasms subsequent to the operation, and the muscular rigidity gradually declined, leaving, however, a certain amount of contracture, which necessitated surgical treatment. The treatment of recurrent tetanus Meyer considers should be purely surgical—excision of all suspected scars, removal of foreign bodies and sequestra, even where these have apparently healed in completely; free opening up of all infected foci, the cavities being allowed to granulate up, in order to prevent the inclusion of spores in the cicatrix. Meyer has appended to his article a description of thirteen cases of recurrent tetanus which have been previously recorded.

55. A Displacement Operation for Wounds of Nerves.

I. F. S. ESSER says that during 1915 he performed displacement operations on the radial and ulnar nerves in thirteen cases (*Amer. Journ. Surg.*, June, 1917). His object was to protect the nerve from the surrounding scars and latent inflammation by displacement, instead of the usual procedure of surrounding it with protecting calf's arteries and veins. An envelopment of the nerve with a pedicled muscle flap seemed theoretically preferable, but even this procedure was not as satisfactory as displacing the nerve into a healthy muscle interstice. Esser very carefully frees the nerve for a long distance, both at the seat of injury and above and below it; in this procedure recourse must often be had to the chisel, as the nerve ends are very often surrounded by callus and bone splinters. The nerve ends must be freed from every particle of connective tissue. To do this thoroughly Esser always operated under plexus-conducting anaesthesia, so that half an hour more or less was of no consequence. The plexus anaesthesia demands extreme precision, patience, and much practice, but its results are worth the time and trouble expended. In all his thirteen cases Esser found remnants of the nerve connexions of both ends. In no case was impairment of nerve function proved by examination of the active movement and the electrical susceptibility and response immediately after operation. The following was his technique: After scrupulously clean preparation of the injured nerve, the ends were joined by sewing the nerve sheaths together with the finest vessel sutures. Then the thin connexion, carefully prepared beforehand, hung like a free loop. The brachialis internus and biceps were next sewn together beneath the raised nerve, and the liberated nerve was laid in the groove between those muscles and covered only with subcutaneous fat and skin.

56. Treatment of Wounds of Peripheral Nerves.

G. LUSENA, in a communication to the twenty-fifth congress of the Italian Surgical Society held at Bologna (*Morgagni*, June 23rd, 1917), stated that between August, 1915, and the date of his report he had treated 55 cases of lesions of peripheral nerves. The operations were done at a minimum of twenty-nine and a maximum of 508 days from the time of injury. By means of simple neurolysis two complete and two almost complete cures were obtained; neurolysis and resection with direct suture gave three complete, seven almost complete cures, and seven

of notable and progressive improvement; resection and distant suture yielded one case of complete cure; simple resection in two cases of pure syndrome of sensory irritation brought about the immediate cessation of the subjective symptoms with the necessary consequence of regional anaesthesia. In many other cases signs of amelioration were observed; among these were some operated on two months before—all instances of lesion of the ulnar nerve. Lusena pointed out that from statistics of other surgeons it might be inferred that in about 80 per cent. of cases restoration of function takes place naturally; in his own series this result was observed in 75 per cent. Regeneration occurs naturally by restoration of nervous conductivity along the injured trunk. It is not seen when a permanent obstacle to conductivity is formed at the seat of the lesion. In gunshot wounds the obstacle is seldom due to division of the nerve with separation of the ends; less rarely it is due to a dense mass of connective tissue surrounding and stretching the nerve; much more often it is caused by the interposition of dense connective tissue between the ends. It is extremely rare for natural restoration to begin after the first six to ten weeks; later this is quite exceptional. If it does not begin within two to eight weeks muscular changes, beginning with mechanical hyperexcitability and going on to complete reaction of degeneration, occur. If these become more marked, intervention is indicated. In regard to the choice of procedure, if Lusena finds a mass of dense connective tissue surrounding the nerve trunk, he performs neurolysis; if there are one or two masses of dense fibrous tissue, he practises resection followed by direct suture, either stretching the ends or bringing the stumps together with fine catgut. The region of operation should be surrounded with muscular bundles parallel to the nerve trunk. If these methods prove ineffective, recourse may be had to the interposition of transplanted nerves—free, autoplasmic, haemoplastic, or heteroplastic. Lusena does not use a haemostatic bandage from fear of subsequent haemorrhage and the production of other nerve lesions, especially in the arm. Resections are confined to some bundles of a nerve if these are the seat of cicatricial masses which interrupt conductivity. Reaction of degeneration persists many weeks or even months after clinical cure. Electrical treatment should be begun as soon as the operation wound is healed. The application of a movable apparatus to prevent excessive stretching of the paralysed muscles by the force of their antagonists is often useful. To establish the fact of clinical recovery the restoration of motor function must be investigated, since the return of sensibility, particularly in the primary anaesthetic zone, is not a sign of restoration of nervous conductivity.

57. Cheap Dressings.

FRANÇOIS DEBAT, head of the dermatological centre of the 8th French region (*Paris méd.*, May 26th, 1917) states that he has effected a considerable economy in the cost of dressings by using strips and squares cut out of old bed-linen instead of gauze compresses, tarlatan, and cotton bandages, etc. The advantage is that whereas gauze, tarlatan, and cotton are very dear and can be used only once, old linen costs nothing, and after sterilization and washing can be used over and over again. In his service of 180 beds the dressings have to be renewed almost every day, and the monthly cost, which used to be £56, is now a little over three guineas—a reduction of more than 90 per cent., representing a total saving of more than £600 a year. The old bed-linen is supplied for nothing by the military hospitals and by private charity. It is cut into pieces of suitable size and sterilized by boiling. After a trial of three months during a period of very active work, Debat declares that the method has no disadvantages in the treatment of superficial sores and skin affections. The work of the nurses is facilitated, the dressings being easy to make and taking little time.

THERAPEUTICS.

58. Treatment of Epidemic Jaundice.

In a communication to the Royal Academy of Medicine of Turin CARLO FOÀ (*Morgagni*, September 22nd, 1917) said he had tried the drugs generally credited with remedial properties in protozoal diseases in a number of cases of epidemic jaundice. He divided the patients into seven groups, all the cases chosen being in the early stage of the disease and almost all showing the symptoms in equal intensity. To one group of 5 cases quinine bisulphate

was given in daily doses of 1.5 grams by the mouth for six consecutive days. To a second group of 5 cases crystallized chemically pure methylene blue was given by the mouth in daily doses of 8 centigrams divided into four equal cachets for six consecutive days. To a third group of 7 cases a daily intramuscular injection of 2 centigrams of methylene blue dissolved in 1 cubic centimetre of distilled water was given for six consecutive days. To a fourth group of 10 six intramuscular injections of atoxyl (0.30 gram each) were given on six consecutive days. To a fifth group of 2 cases three intravenous injections of Billon's novarsenobenzol (formula of neo-salvarsan) were given on three consecutive days in increasing doses (0.15, 0.30, and 0.45 gram) dissolved in 5 c.cm. of a cold sterilized solution of sodium chloride (4 per cent.). To a sixth group of 11 cases an intramuscular injection of mercury bichloride in doses of 1 centigram each was given on six consecutive days. To a seventh group of 40 cases a single intramuscular injection of calomel was given. The results were as follows: In the first six groups the remedy produced no appreciable effect, and such improvement as took place was the same as might have been expected without any treatment: the illness had the usual duration of twenty to thirty days. The calomel injection was followed by distinct improvement, starting from the fourth or fifth day; this showed itself in the colour of the skin, mucous membranes, and urine, and went on increasing so that at the end of ten or twelve days hardly any visible trace of the disease remained. In 3 cases the cure was delayed till about the twentieth day.

59. X Rays in Rhinoscleroma.

MACKEE (*Amer. Journ. of Roentgenol.*, April, 1917) considers rhinoscleroma a typical example of the group of dermatoses in which x rays or radium offer the best means of permanent cure. As a large total dosage of x rays is required, unless the disease is in its early stage, an intensive technique is indicated. Deep therapy is also called for, so that filtration is required. If the disease is limited to the alae nasi, an unfiltered ray may be directed into the nasal orifices; two or three doses of from $\frac{3}{4}$ to 1 Holzknecht unit will usually suffice for a cure. In extensive cases it is advisable to divide the nose into several areas for the purpose of cross-firing, each area to receive from $\frac{1}{4}$ to 2 H., filtered through 3 mm. of aluminium, every four to six weeks. The hardness of the ray should be Benoist 9-10. In addition, a radium plaque may be placed against the hard palate, and a dose of gamma rays also administered. Several—perhaps eight or ten—series of cross-fire treatments may be required to produce the desired result in extensive and long-standing cases. Lesions situated in the nose, at the posterior nares, or in the pharynx, will usually disappear as a result of deep therapy applied to the nose. If necessary, this treatment may be reinforced by the application of radium to the pharyngeal walls or the x rays may be applied to these parts through a metal mouth tube.

60. Electricity in the Treatment of Scars.

SREUWEN (*Arch. Radiol. and Electrother.*, October, 1917), writing of the treatment of the wounded by means of electricity, says that when a scar is painful or adherent, or both, he gives massage thrice a week, preceded by an application of hot air or radiant heat. The duration of the hot air or radiant heat treatment depends on the sensibility of the scar and of the patient. If after three or four minutes' hot air application the skin around the scar becomes pink, the time has been sufficient; otherwise the application may continue for five or six minutes if the patient can stand it. Radiant heat may go on for longer—even for ten or twenty minutes. On the other days of the week, alternating with the massage, ionization with a 2 per cent. solution of sodium chloride or potassium iodide is given. The active electrode is made with at least twelve layers of gauze, slightly exceeding the size of the scar, well soaked in hot solution. The indifferent electrode, as large as possible, is soaked with plain hot water and placed on the back or chest; in some cases, instead of a pad electrode, a bath is used for arm or leg. The intensity of the current varies from $\frac{1}{2}$ to 1 milliampère for each square centimetre of the active electrode, or nearly 3 to 6 milliampères to the square inch. The application lasts about fifteen to twenty minutes, sometimes longer. The results of this combined treatment have been very satisfactory; the first sign of improvement is generally a diminution of the pain. The average duration of treatment for the simple uncomplicated scar has been from six weeks to two months. The reason why many scars remain painful and unhealthy is because other foreign

bodies than those which the x-ray plate can detect—such as small quantities of dust and very tiny bits of clothing—remain embedded in the tissues.

PATHOLOGY.

61. Persistence of Intestinal Amoebiasis.

THE carrier question in amoebic dysentery has come into special prominence during the war, and valuable work has been done by Clifford Dobell, under the aegis of the Medical Research Committee, in showing the necessity for more extended examination of the stools for *Entamoeba histolytica* than had previously been thought necessary before the infection could be regarded as "cured." These investigations were made in this country on patients sent home from the Eastern Mediterranean, and there is therefore need for information on the problem of the carrier question in the tropics. For example, very little is known about the results of systematic examination of the stools of troops in India for *Entamoeba histolytica*. From the protozoological findings in the stools of over 2,000 men, chiefly of the Mesopotamia Field Force, carried out at Deolali, India, MACADAM and KEELAN (*Indian Journ. Med. Research*, Calcutta, 1917, v. pp. 239-272) have drawn some important deductions. In the first place it appears that, after applying Dobell's appropriate "figure for correction" to those results obtained on a single examination method, at least 33 per cent. of the troops that have been in Mesopotamia are "healthy" or "unhealthy" *histolytica* carriers. Further, it is disquieting to find that there is a fallacy in concluding from protozoological examination of the stools in hospital that the patient is clear from infection. In hospital the possibilities of intestinal irritation are reduced to a minimum; but when the patient is discharged, coarse food, excessive exertion and fatigue, and the lack of hospital discipline as regards diet and drink may cause intestinal catarrh, and the reappearance of *histolytica* cysts in the faeces. This difference was also seen in the case of hospital and convalescent camp patients, the percentage of carriers being higher in the camp patients whose conditions formed a faint replica of active service. Further, the percentage of carriers was higher in men who had been a week in the camp than among those just admitted. In order to test for the presence of latent infection the authors make a routine practice of giving a mild saline to all convalescent dysentery patients, thereby causing some intestinal irritation. Although the softer condition of the faeces may lead to a more equal distribution of the cysts, it is probable that the flooding out of the cysts due to the flushing of the mucous membrane of the intestine is an equally important factor. The high percentage of *histolytica* infection among men not suspected of any intestinal disorder, and the apparent failure of hypodermic courses of emetine to rid men of this infection, throw considerable doubt on the utility of attempting to "clear" by a series of protozoological examinations of the stools only, those cases of amoebic infection which have had sufficient intestinal disturbance to demand hospital treatment. Among 87 *histolytica* carriers in the convalescent dépôt with a history of previous dysentery there was an average interval of 8.5 months between the first attack and the examination of the faeces. The authors come to the conclusion that the segregation of any but the "gross" human carriers is impossible and futile; and that, as light and intermittent infections appear to be present in at least a third of the troops, it is doubtful if the isolation of a few gross carriers will be of much use in prophylaxis.

62. Serum Treatment of "Bacillus welchii" Infections.

IN a preliminary paper¹ it was shown that the *Bacillus welchii*, like *B. tetani* and *B. diptheriae*, produces an exotoxin, and further, that injection of this toxin into animals yields an immune serum, which prevents and controls infections with both the spore and vegetative forms of the bacilli. C. G. BULL (*Journ. Exper. Med.*, Baltimore, 1917, xxvii) now brings forward more extensive and systematic experiments, which show that in all probability a passive immunity to *B. welchii* of at least two weeks' duration can be conferred on man by a single injection of the antitoxic serum; and in the light of the results obtained in treating the infection in guinea-pigs, that the serum will also exert a curative action. The immunity conferred by a single injection will be sufficient in most instances, since the majority of cases of infection with *B. welchii* occur within forty-eight hours of the

injury, and sporadic examples only are seen after an interval of ten days. The serum is now prepared in the horse, and the method employed and the standardization will be described in a later communication.

SKIAGRAPHY.

63. X-ray Characteristics of Shrapnel Balls.

HOWARD PIRIE (*Arch. Radiol. and Electrother.*, October, 1917), on a basis of 10,000 x-ray findings, compares the characteristics of the x-ray image of shrapnel balls with that of bullets and other foreign bodies. He states that shrapnel balls, which are most usually of lead, though sometimes of iron, may be found entire without any alteration of shape, and every stage of deformity may be met with until an appearance is obtained as if the ball had exploded into fine particles. Only two bones, in the author's experience, have proved impenetrable to shrapnel balls, namely, the femur in its shaft, and the vault of the skull; he has no record of a case in which a shrapnel ball entered the brain. The x-ray characteristics of a shrapnel ball when broken up are rounded or slightly ragged edges, scarcely if at all serrated; one piece may show part of the round outline of the ball, and minute fragments like dust are noticeable along its track. In the broken-up bullet the larger pieces are very ragged; one piece may show something of the form of the bullet, and there are minute dust-like fragments. In multiple iron foreign bodies the edges are serrated like broken cast-iron; the fragments are not so numerous as in the broken-up ball or bullet, and when numerous fragments are present they are more widely separated, and there are many separate wounds of entry; dust-like particles are absent. The contrast between damage done by a bullet and that done by a shrapnel ball is very marked in cases where a direct hit is made on the femur or on the skull. A bullet hitting the femur splinters the bone as it does a glass bottle; at the same time the bullet breaks into pieces, and its fragments and those of the femur are scattered through the limb. In the case of the shrapnel ball, when the femur had received a direct hit, the ball was broken into two or more pieces, and had just roughened the bone surface.

64. The Pathological Gall Bladder.

GEORGE and LEONARD (*Amer. Journ. of Roentgenol.*, July, 1917) state that only when some pathological change has taken place in the walls of the gall bladder or its contents can its shadow be demonstrated on the x-ray plate. When the shadow of a gall bladder is "visualized" it must be pathological, by which they mean that either the walls of the gall bladder are thickened or that the bile content is of greater density than normal, or greater in quantity, or that it contains stones or calcium in some form. The authors further maintain that the operating surgeon cannot determine by simple palpation and inspection whether or not the gall bladder is normal, and that even if the gall bladder be opened, simple inspection of its interior is not sufficient to determine the presence or absence of disease. Only by removal of the gall bladder and microscopic examination can the absence of disease be made certain. Some workers have claimed that normal gall bladders are visible on the x-ray plate. To this it is replied that just as some "normal" individuals may show gall stones, so a few healthy persons may have technically pathological gall bladders without clinical symptoms.

GYNAECOLOGY.

65. Cancer of the Cervix after Subtotal Hysterectomy.

RALPH WORRALL (*Medical Journal of Australia*, June 23rd, 1917) reports a case of cancer of the cervix uteri in a patient in the Sydney Hospital upon whom subtotal hysterectomy for fibroids had been performed elsewhere three years previously. The growth was a papillary form of squamous-celled epithelioma. Wertheim's radical operation was performed on March 1st and was followed by favourable convalescence. The author suggests that subtotal hysterectomy for myoma should be abandoned in favour of total hysterectomy by the abdominal method, which he now performs—when such an operation is indicated—in all cases associated with diseased or injured cervix. The time has come, he thinks, when the type of operation for such cases should be reconsidered by gynaecologists.

CURRENT NOTES.

Emergency Committee.

At its last quarterly meeting the Council of the Association appointed an Emergency Committee consisting of the officers of the Association, the chairmen of the Medico-Political, Public Health, Hospitals, and Insurance Acts Committees, with the addition, at the Chairman of Council's discretion, of the chairman of any other committee concerned. The duty of this committee will be to take such immediate action as may be necessary with regard to matters which are the subject of recommendation by a Standing Committee or which come within the scope of more than one Standing Committee.

Payment of Medical Officers to V.A.D. Hospitals.

With reference to the payment of medical men who render services at Voluntary Aid Hospitals, it may now be stated that—

1. Every man so employed may be paid.
2. The discretion of the D.D.M.S. of each command is twofold: (a) He may decide that the work could be carried on efficiently without the full staff employed at a particular hospital. Thus, if three medical men render services which could be done by one, it is within the competence of the D.D.M.S. to pay only one. (b) The amount of pay given is decided by the D.D.M.S. It appears to vary in different commands from 10s. a day to 2d. or 3d. a day for each occupied bed.
3. Whatever sum is given is *pay*, and not reimbursement of out-of-pocket expenses. In certain commands an attempt has been made by the D.D.M.S. to adopt the latter view, and to suggest that the sum allocated is for the purpose of covering cost of petrol, etc. This is not so.
4. It is left to the county directors to inform medical men of the possibility of payment.

Thus it will be seen that every medical man whose services are used in a Voluntary Aid hospital is entitled to be paid, provided those services are necessary to the carrying on of the hospital. The unfortunate mystery in which the original decision to grant pay, if desired, was shrouded has led to a very anomalous state of affairs. Hence it would be only fair that payment should be made retrospective where desired. But great difficulty would arise from the financial side of the War Office, and it may be doubted whether it is possible now to calculate amounts due on a retrospective basis. We understand that in some areas medical men are disinclined to accept payment for their services to V.A.D. hospitals. Consequently, we must remind our readers that Deputy Directors of Medical Services have the whip hand wherever they are able to get men who do not desire payment to take over the work at such hospitals. Whether the position in which the whole question now stands is acceptable to the majority of the profession we do not know. But if it happens to be a fact that a majority of medical men are disinclined to accept payment, this would make it somewhat difficult for any professional body to press for a proper arrangement. It will be of great interest to see what view is adopted by the Representative Meeting on July 26th.

Civil and Military Needs.

It will be remembered that when the War Office in the third week of last April decided to call up all medical men of military age, the procedure laid down by the military authorities was that a practitioner ready to accept a commission in the R.A.M.C., and proceed at once on active service, should sign a form of contract and await instructions, holding himself in readiness to join for service at forty-eight hours' notice. But owing to the strong representations made by the central professional bodies, Lord Derby agreed that the procedure hitherto prevailing with regard to the selection of doctors should be continued, and that no commission would be given to any doctor except on the recommendation of one of the professional bodies. In the meanwhile, however, a number of medical men under the age of 41 had been called up and accepted by the Army Medical Department, some being sent direct to the new R.A.M.C. dépôt at Blackpool. Needless to say, it took some time for the Central Medical War Committee to recover from the dislocation of business caused by the action of the War Office and its subsequent reversal.

We have received a number of letters from readers with regard to the effect upon the civil population and medical profession of the repeated and insistent calls for more medical men for the army, of which Lord Derby's letter to the profession on April 21st was perhaps the most urgent and emphatic. Dr. Vaughan Pendred (East Sheen), writing on this subject, expresses in forcible terms a point of view which we know to be widely held. After pointing out that the civil hospital staffs are depleted, and the ranks of private practitioners dangerously thinned in many places, he challenges the military authorities to defend the use to which they have put the greater number of practitioners taken from civilian work. He maintains that in Malta, Mesopotamia, Egypt, and India there are hundreds of medical men kept in reserve for emergencies which never arise, who are doing next to nothing, and often nothing at all. "We are as patriotic a profession as exists, but these useless demands for very expensive services—services that are not required—is irritating the profession beyond endurance." As an instance he quotes the case of a member of a busy partnership—already reduced from three to two—who was sent to Blackpool at the end of April, "and is still there doing nothing." Dr. Pendred, in conclusion, claims that if the scheme for summoning medical men at forty-eight hours' notice, as soon as their services were really needed, and not before, had been put into action, the difficulty would have been solved, and the present resentment so keenly felt would have abated.

SPECIAL NOTICE TO MEMBERS.

Every member is requested to preserve this SUPPLEMENT, which contains matters specially referred to Divisions, until the subjects have been discussed by the Division to which he belongs.

By Order,

[689]

MATTERS REFERRED TO DIVISIONS.

British Medical Association.

SUPPLEMENTARY REPORT OF
COUNCIL, 1916-17.

(A) Preliminary.

OBITUARY.

159. Since the publication of the Annual Report the Council has received with much regret intimation of the deaths of Dr. J. Mitford Atkinson, a former representative of the Hong Kong and Malaya Branches on the Council; Inspector-General Robert Bentham, at one time representative of the Royal Naval Medical Service; Lt.-Col. Davie Harris, a former representative of the Royal Army Medical Corps; and Dr. Major Greenwood, who for many years has been a most active and valued member of the Association, a member of the Council, a Representative, and a member of the Insurance Acts and Public Health Committees.

HONOURS CONFERRED ON MEMBERS OF THE COUNCIL.

160. The Council has heard with great pleasure of the conferring of the C.B. on Col. James Galloway, representing the Metropolitan Counties Branch on the Council, and the C.M.G. on Lt.-Col. W. T. Hayward, representing the Australasian Branches.

(C) Central Medical War Committee.

NEW MEMBERS.

(Continuation of paragraph 21, p. 86, of Annual Report of Council, Supplement to *B.M.J.* of May 5th, 1917).

161. In its last Report the Committee reported the resignation of Major Russell Coombe. The vacancy has been filled by the appointment of Lt.-Col. J. Michell Clarke of Bristol. The Committee has further increased its membership by the addition of the following five gentlemen:—

Drs. H. J. Campbell (Bradford), H. J. Cardale (Cubitt Town), T. W. H. Garstang (late of Altrincham), Arnold Lyndon (Hindhead), and H. J. Starling (Norwich).

These additions were made because the large number of appeals pending and the necessity of dealing with them without delay rendered it very desirable that a larger number of members should be available for appeal purposes. As appeals are being heard nearly every week, and sometimes two days in the week, it is not always easy to keep together the quorum necessary for each of the two sections sitting. It is now possible to divide the Committee into three sections for appeal purposes. Through an alteration of the Order in Council these changes apply not only to the Central Medical War Committee but also to the Central Professional Committee for England and Wales under the Military Service Act.

Opportunity was taken, in adding to the Committee, to secure representatives of certain important areas, which up to then had not been represented on the Committee. These additions will, it is believed, not only make the Committee capable of dealing with its work more expeditiously, but will bring into the common stock much local and personal knowledge of the profession which will be invaluable.

SUPPLY OF MEDICAL MEN FOR THE ARMY.

(Continuation of paragraph 24, p. 81, of Annual Report).

162. After the reply from Lord Derby of April 25th, which was quoted in the last report of the Committee, the Committee informed him that it was unable to guarantee to supply his demands in the time stated, though it would do its utmost; and that the recent action of the War Office had disorganised the machinery of the Committee very considerably, thus making the task even more difficult. Lord Derby's attention was called to the urgent need of economies in the use of doctors (1) in all kinds of civil employment, and (2) in the Army Medical Department, and the Committee stated its opinion that many such economies might be expected from thorough co-operation between the military authorities and the Central and Local Committees. To this Lord Derby replied on April 28th agreeing with the Committee as regards the measures it thought the Government should adopt, and promising to fall in as far as he

NOTE.—The Sections numbered (A), (C), etc., of the Supplementary Report are continuations, respectively, of the similarly lettered sections of the Annual Report, published in the SUPPLEMENT of May 5th, 1917. The paragraphs of the Supplementary Report are numbered consecutively to those of the Annual Report.

possibly could with any suggestions the Committee might make. On June 2nd the Committee informed Lord Derby of the methods by which it was proceeding to estimate and call up the maximum number of medical men who could be spared for the Army with due regard for minimum civil requirements, and stated that it was doubtful whether under existing powers and conditions the number of men at present demanded by him could be provided at any time. The Committee again pressed on his attention the measures which it had previously indicated as being necessary if more men were safely to be released, namely (1) legislative compulsion for the civil employment of medical practitioners, (2) economies in the use of doctors in the Army, and (3) co-operation between the military authorities and representatives of the civil medical profession. The Committee also drew attention to the announcement that large numbers of American doctors were shortly to be available at the front, and suggested that these should be able to relieve the pressure on the profession in this country. To this the only reply that has so far been received from Lord Derby is a letter of June 12th, recognising the extreme difficulty of freeing the number of doctors required, and also that it may prove impossible to release that number, and enquiring as to the definite date after which, with due regard to the needs of the civil population, the Committee can supply no more doctors. The Director-General A.M.S. has stated that it would be unsafe and unwise to permit the advent of assistance from the United States to modify in any way the demands that have to be made on the British profession.

In order to ascertain the maximum number of men who can be released, a Local Arrangements Sub-Committee under the Chairmanship of Dr. T. W. Shore is closely scrutinising the names of all men of military age in each area in England and Wales, with the help of all the information the Committee has in its possession, and often with the personal assistance of representatives of the Local Committees who are asked to attend for this purpose. The Committee then decides, on the report of this Sub-Committee, which of the men it is obvious cannot be spared, which are doubtful, and which seem *prima facie* spareable, and the men in the two latter classes are then given their right of appeal. This is very laborious work, but when it is completed, as it is hoped it will be within the next few weeks, it will be possible to say that with few exceptions the military authorities have in their hands all the eligible men of military service age who under existing powers and conditions can safely be allowed to leave civil practice. It may interest the profession to know that up to June 21st, the Committee has dealt with 512 appeals.

À LA SUITE TERRITORIAL OFFICERS.

163. Questions have been raised from time to time by Local Medical War Committees as to the position of Territorial Medical Officers who are *à la suite* of Territorial General Hospitals, and have accepted the imperial service obligation to serve abroad when called upon. When these officers were appointed it was contemplated that they would remain available for the civil needs, hospital and private, in their area. But by accepting the imperial service obligation they have placed themselves at the disposal of the military authorities, and may be called upon at any time to take service abroad. This position has caused considerable alarm in some areas in which, if the military authorities exercised their right, the localities would find themselves almost entirely deprived of skilled specialist professional assistance, and in some cases of necessary general practitioners. On May 18th the Committee received a deputation from the British Hospitals Association which asked for the assistance of the Committee in securing so far as possible, that the War Office would not call on the officers in question for foreign service without previous consultation with representatives on the civil side. A letter has therefore been addressed to the Director-General, A.M.S., asking that his Department should inform the Committee whenever any action in the way of calling upon those officers for foreign service is contemplated, and that he should suggest means whereby Local Committees can be assured that a sufficient supply of specialist assistance will be retained in their areas.

DEMOBILISATION.

164. The Committee has commenced consideration of the important and intricate question of demobilisation as it will affect the medical profession, and has appointed a small Sub-Committee to make a preliminary survey of the whole position.

PAYMENT OF MEDICAL OFFICERS OF V.A.D. HOSPITALS.

165. At the last Representative Meeting a motion was moved on the consideration of the report of the Committee, in favour of the principle of payment for the services of practitioners working at V.A.D. Hospitals, but it was evident that there was considerable diversity of opinion on the subject, and the motion was allowed to drop. Since that time the subject

has again been revived, partly because the duration of the War has compelled some of the practitioners concerned to reconsider their position as unpaid officers, but mainly owing to the fact that though authority had been given by the War Office to Commanding Officers to make payment to such practitioners as asked for it, no steps had been taken to secure that practitioners concerned should be aware of this. The Committee has endeavoured to obtain from the War Office the instructions on the subject which were issued to Commanding Officers so far back as June 1915, but without success. In the opinion of the Committee the action of the authorities in this matter has been far from happy, as the air of mystery with which these instructions were surrounded has given rise to misunderstanding and irritation which might and should have been avoided. The Committee has now been informed by the War Office that medical officers in V.A.D. Hospitals who wish for such remuneration should make application on Form P. 62 through the Commandant of the hospital to the General Officer Commanding in Chief of the command in which the hospital is situated. It is hoped that the arrangements are sufficiently elastic to enable the payments to be made with due regard to the time and trouble involved in rendering the services, and it is considered that under all circumstances the payment to such as desire it should be made retrospective.

RENEWAL OF THE MANDATE OF L.M.W.C.S.

166. Most of the Local Medical War Committees now in office were appointed so far back as August and September of 1915. Some of them have since been modified in composition by meetings of the local profession; many have from time to time called meetings of the whole local profession and rendered an account of their work. In view of the length of time that has elapsed since the election of most Local Committees, and of the increased responsibilities that have been imposed on them during the past year, and the possibility of still further additions if the war continues much longer, the Committee feels that it would be a politic and useful thing for all Local Medical War Committees (excepting any that have recently been elected or re-elected) to call a meeting of the whole local profession at which they would render an account of their stewardship and give an opportunity to the meeting to renew the mandate under which the Committee represents its constituents. To this meeting every local practitioner should be summoned, whether a Member of the Association or not. The Central Committee has conveyed this instruction to the Secretary of every Local Committee in England and Wales, accompanying it with an expression of its thanks for the invaluable assistance which those bodies have rendered not only to the Central Committee but to the medical profession and the State.

Proposed Loan Fund for Assistance of Practitioners Suffering Loss by taking Naval or Military Service.

167. At its October Meeting the Council considered a proposal to form a Loan Fund, and arrived at the following conclusions:—

1. That a case has been made out for the formation of a Fund to assist by loans those medical practitioners who suffer financial loss owing to taking service with the Navy and Army.
2. That an *ad hoc* Committee should be appointed to take all necessary steps to create such a Fund.
3. That the Fund should be initiated and administered so that the liability of each contributor is limited.

The Special Committee was elected and invitations sent to other representative medical bodies, asking them to take part in determining the character of, and initiating the proposed Fund.

Constitution of Committee.

Royal College of Physicians of London; Royal College of Surgeons of England; Royal College of Physicians, Edinburgh; Royal College of Surgeons, Edinburgh; Epsom College; Royal Medical Benevolent Fund; Scottish Committee of the B.M.A.; Irish Committee of the B.M.A.

The British Medical Association: The President, Chairman of Representative Meetings, Chairman of Council, Treasurer, Chairman of Central Medical War Committee, Lt.-Col. R. A. Bolam, Dr. William Collier, Mr. N. Bishop Harman, Dr. C. O. Hawthorne, Dr. R. McKenzie Johnston.

The Corporations appointed respectively:—

Royal College of Physicians of London (Dr. Sidney Phillips, *pro tem.*); Royal College of Surgeons of England (Mr. H. J. Waring); Royal College of Physicians of Edinburgh (unable to appoint a representative as they had not sufficient information with regard to the proposals to warrant them in committing the College in any way); Royal College of Surgeons of Edinburgh (Dr. R. McKenzie

Johnston); Epsom College (Sir Henry Morris, Bart.); Royal Medical Benevolent Fund (Dr. Samuel West); Scottish Committee of the B.M.A. (Dr. John Adams); Irish Committee of the B.M.A. (Dr. T. Hennessy).

The Committee generally reviewed the question and appointed a Sub-Committee to investigate the best methods of initiating and administering such a Fund.

Report of Sub-Committee.

The Sub-Committee, under the chairmanship of Mr. Bishop Harman, held three meetings and collected much valuable data.

It formulated a report which was circulated to the Council, but the Sub-Committee decided that it would be inadvisable to proceed with the launching of the scheme since: (1) it would clash with the issue of the War Loan; (2) its success might be affected by uncertainty concerning the possible mobilisation of the medical profession. The members of the full Committee were consulted and endorsed the opinion of the Sub-Committee. The Council accordingly resolved that no further action should be taken at present.

Medical Recruiting Boards.

168. The Council had before it on June 27th the report of the debate in the House of Commons on June 21st, when severe strictures were passed on the medical examination of recruits. The Council has appointed a small Committee to watch the proceedings of the Select Committee which has been appointed to examine into the working of the Review of Exceptions Act, and the method, conduct and general administration of medical examinations under the Military Service Acts. The Committee appointed by the Council has been given power to take such action as may be necessary.

(D) Organisation.

GROUPING OF DIVISIONS FOR ELECTION OF REPRESENTATIVE BODY, 1917-18.

(Continuation of para. 38, p. 84, of Annual Report.)

169. The Council has settled the list of Constituencies in the R.B., 1917-18, having grouped the Divisions in the same way as for 1916-17 (Supplement, July 3rd, 1915, p. 9), making necessary formal adjustments in respect of changes in Division areas effected since the 1916-17 grouping was decided.

GROUPING OF HOME CONSTITUENCIES FOR ELECTION OF 12 MEMBERS OF COUNCIL.

(a) Council, 1917-18.

170. Acting on the authority conferred by Min. 176 of the A.R.M., 1916, the Council has grouped the Home Constituencies for election of 12 members of Council, 1917-18, in the same way as for 1916-17.

(b) Council, 1918-19.

171. The Council recommends:

Recommendation.—That, as in the case of the 1917-18 grouping, the grouping of Constituencies for election of 12 members of Council, 1918-19, be left to the Council.

REPORTS OF DIVISIONS AND BRANCHES FOR 1916.

(Continuation of para. 40, p. 84, of Annual Report.)

172. Notwithstanding the War conditions, reports have, up to June 20th, been received by the Council as follows:—

	Total	No. which have reported.
Home Divisions ...	207	141
Home Branches ...	41	37
Oversea Divisions ...	16	1
Oversea Branches ...	43	13

GRANTS TO BRANCHES.

(Continuation of paras. 42-4, p. 84, of Annual Report.)

173. In all, up to June 20th, the Council has allotted grants, varying from 1s. to 4s., to 31 of the 41 Home Branches. Of the remainder, 6 Branches required no grant, having in hand, from 1916, balances sufficient for financing their current work. The question of grants to the remaining Branches is held over by the Council pending receipt of reports by these Branches for 1916.

MEMBERSHIP.

(Continuation of para. 41, p. 84, of Annual Report.)

174. During the period January 1st to May 31st, 1917, 397 new members joined, and the Association lost by arrears (201), resignation (233), death (101), and expulsion (1), 536, a net decrease of 139, as compared with 402 in the same period of 1916. On May 31st, 1917, the total membership of the Association was 20,296, as compared with 20,710 at the same

date last year. A gratifying number of applications for membership has been received since May 31st.

DIVISION AND BRANCH AREAS.

175. A new Division of the Yorkshire Branch, the Dewsbury Division, has been formed. Wallingford has been transferred from the Oxford to the Reading Division of the Oxford and Reading Branch.

CONFERENCE OF SECRETARIES.

176. In view of the War conditions the Council has decided, as in 1915 and 1916, to hold no Conference of Secretaries in 1917.

EXECUTIVE PROCEDURE OF ASSOCIATION.

(Continuation of para. 50, p. 85, of Annual Report.)

177. The Council has considered the fact that after the War the position of every practitioner, in whatsoever class of practice he or she may be engaged, may be gravely affected by legislation or social schemes, and the question of what, if any, change should be made in the executive procedure of the Association so that it may be possible to take the promptest and most effective action in cases of medico-political urgency.

In this connection the Council has also considered the views of a deputation from the Oldham Division as to the need for an 'Intelligence' Department of the Association. The deputation expressed the view that the Association should make more use of the lay press in educating the public as to the views of the profession on matters affecting public health, e.g., the Ministry of Health suggested by the Government, and the whole-time State Medical Service advocated by the medical correspondent of the *Times*, to which there had not been a counterblast in any other paper. The deputation felt that the Association should endeavour to obtain by means of an agent of its own or a subsidised representative of a newspaper in the lobby of the House of Commons, the latest information as to proposals for legislation, prior to such being embodied in Bills. The Chairmen's Committee pointed out to the deputation the existing procedure of the Association in obtaining up-to-date political information affecting the profession, and the parliamentary work generally of the Association, a work naturally somewhat curtailed owing to the depletion of staff due to the War, and to the extra work thrown on the Medical Department by the activities of the C.M.W.C. The Committee assured the deputation that the question upon which they urged action was one to which the Council attached great importance.

The deputation further urged that, while it was possibly not politic to publish all information broadcast in the *Journal*, the Council should provide for early confidential information being issued periodically to Division and Branch Secretaries, in order that they might watch and report to the Head Office as to local occurrences of medico-political interest.

To provide more effectively for the class of cases where the necessity of urgent action arises as to matters which must be the subject of recommendation by a Standing Committee to the Council and/or Representative Body, or cases which come within the scope of more than one Standing Committee, the Council has appointed an Emergency Committee consisting of the Officers of the Association, the Chairmen of the Medico-Political, Public Health, Hospitals and Insurance Acts Committees, with the addition, at the Chairman of Council's discretion, of the Chairman of any other Committee concerned. The duty of this Committee will be to take such action as they may think desirable in respect of any such emergency.

UNDER CONSIDERATION.

178. Question of Association subscription in Ireland.

(F) Science.

INCREASED LENDING LIBRARY FACILITIES.

(Continuation of para. 46, p. 85, of Annual Report.)

179. The Council has made arrangements whereby books relating to all branches of medical literature and general science are now obtainable on loan by members of the Association, free of charge (other than postage), from the Lending Department of the Library, 429, Strand. The new facilities include, besides works on medicine, surgery, anatomy, physiology, bacteriology, dentistry, hygiene, obstetrics, and the other branches of medical and surgical science, the subjects of astronomy, biology, botany, chemistry, electricity, engineering, geology, microscopy, mining, physics, philosophy, sociology, technology, voyages and travels, zoology, etc. All such books issued will be latest editions, new books and new editions becoming available immediately upon publication.

The new facilities are additional to those which were already available for the loan to members, of medical journals and periodicals, scientific reports of hospitals and laboratories,

transactions of societies and congresses, and reports issued by States and municipalities, including those of commissions and committees appointed by States, municipalities, and legislative bodies.

The rules in respect of the new facilities, of which a considerable number of members are already availing themselves, are similar to the previous rules. Copies of the rules and all other information may be obtained on application to the Librarian.

ACCESS TO LIBRARY FOR MEDICAL OFFICERS OF DOMINIONS OR ALLIED FORCES.

180. The Council has intimated to the authorities concerned that the Association will be glad to welcome to the Library any Medical Officers attached to the Forces of the Dominions or of the United States; also to furnish through the officials of the Association any information or assistance that can be given.

MIDDLEMORE PRIZE.

(Continuation of para. 55, p. 85, of Annual Report.)

181. The Council has awarded the Middlemore prize for 1917 to Capt. William Clark Souter, R.A.M.C. (T.F.) for his essay on "Disorders of the eye and of its functions induced by War injuries not directly affecting the eye."

BRITISH PRISONERS OF WAR BOOK SCHEME.

182. The Council has had much pleasure in presenting to the British Prisoners of War Book Scheme (Educational) duplicate copies from the Library of certain books required by that Scheme.

(G) Medical Ethics.

ACTION AGAINST THE ASSOCIATION AND OTHERS.

(Continuation of para. 62, p. 86, of Annual Report.)

183. The trial of the action referred to in para. 62 of the Annual Report of the Council has been further postponed.

(H) Medico-Political.

MATERNITY AND CHILD WELFARE.

(Continuation of para. 77, p. 90, of Annual Report.)

184. The approval of the Association was sought by a lay organisation to an Infant Consultation Centre for educated mothers to be established in London. The Council, however, intimated that the Centre could not meet with the Association's approval, as it purported to provide consultations and advice for mothers and children belonging to classes of the community (i.e., mothers whose husbands were in professions, business, trade, or were officers in either Service) which were quite able to consult their family doctor. At the same time appreciation was expressed of the value of the work proposed to be carried out by the Centre in arranging lectures on infant management.

DUNDEE MATERNITY AND CHILD WELFARE SCHEME.

185. As the result of local and central action the salary for the post of a Woman Practitioner to take charge of the Maternity and Child Welfare Centre in Dundee was raised from £300 to £350, the latter being the minimum recognised by the Association for such work.

MEDICAL CERTIFICATES FOR MUNITION WORKERS.

186. As a result of the recommendations to the Minister of Munitions of the Health of Munition Workers Committee, a form of certificate was issued by the Ministry to national factories and controlled establishments for use in connection with absence of workmen on account of illness. The form was issued by various establishments to the practitioners of the area, with a letter in practically all cases to the effect that the Ministry desired that all future certificates as to absence of workers through illness should be on the prescribed form. A considerable number of practitioners communicated with the Association, and were advised that any fee for the certificate appeared to be payable by the munition worker, and that its amount would vary in the different areas according to the local scale of medical charges. Subsequently the Deputy Medical Secretary interviewed two medical officers of the Welfare and Health Section of the Ministry on the subject, with the result that a letter was received from that Section regretting that the form of certificate was presented to some members of the profession for use before steps had been taken to approach the Association, and asking whether the Association was of opinion that medical practitioners would accept a fee of 1s. for filling up the certificate.

In reply the Council has informed the Welfare and Health Section of the Ministry that in its opinion the fee of 1s. for a medical certificate in the form now suggested by the Ministry of Munitions would not be considered adequate

by the members of the profession, but that the whole matter would be raised at the forthcoming Annual Representative Meeting.

MEDICAL EXAMINATION OF WOMEN SEEKING EMPLOYMENT IN MUNITION FACTORIES.

(Continuation of para. 81, p. 91, of Annual Report.)

187. The Council has urged upon the Ministry of Munitions that the fee for the medical examinations of women seeking employment in munition areas should be 5s. per case instead of the present fee of half a crown, which it considers inadequate payment having regard to the importance of the work, and not likely to attract the best type of medical practitioner. The Ministry, in reply, states that it has had no difficulty in getting the desired medical services at the fee of 2s. 6d.

The Council has reminded the Ministry of Munitions of the importance attached by the latter to medical certificates as to munition workers (Annual Report of Council, page 91, par. 80) and the need urged by the Ministry for special care being taken by doctors as regards the giving of medical certificates.

MEDICAL CERTIFICATES IN CONNECTION WITH POSSIBLE PENSIONS OR GRATUITIES TO DEPENDANTS OF SOLDIERS AND SAILORS KILLED ON ACTIVE SERVICE.

188. The A.R.M. 1916 resolved:—

Minute 55.—That in connection with the giving of certificates by medical practitioners as to the degree of capacity to earn their own livelihood of dependants of deceased soldiers or sailors for the purpose of establishing their claim to pension or gratuity, it is desirable:—

(i.) That there should be a uniform standard of estimating disability to earn;

(ii.) That the work of certification should be done by a board of local practitioners, and should be paid for.

Minute 56.—That it be urged upon the Government that the above proposal would be conducive to public economy and efficiency.

These resolutions were forwarded last autumn to the Statutory War Pensions Committee. No satisfactory result having been noted, the Council has drawn the attention of the Pensions Minister to *Minute 55*, pointing out that individual practitioners are still being requested by dependants of deceased soldiers to fill in the certificates in question, and find it very difficult to do so satisfactorily in the absence of a common standard.

MEDICAL CERTIFICATES ACCOMPANYING APPLICATIONS FOR GRANTS UNDER NAVAL AND MILITARY WAR PENSIONS ACTS.

189. Representations have been made to the Pensions Minister that provision should be made by the State for payment for the medical certificates which some local War Pensions Committees are demanding should accompany applications for grants to meet cases of temporary distress or emergency on the part of the wives, children, or other dependants of soldiers or sailors. From evidence received it appears very desirable that practitioners should make a stand against the assumption which seems to be so common, namely, that these certificates are of such small consequence that practitioners will without demur grant them gratuitously. If it were merely a matter of charity to the dependants of men who have fought for the country, the members of the profession would, of course, be as willing to give their services as they always are in suitable cases. But no question of charity arises. The dependants of soldiers and sailors are under the care of the State, and the State has no right to demand the services of any class of the community as a charity.

QUESTION OF RECOGNITION BY THE ASSOCIATION OF MEDICAL AID INSTITUTES IN SOUTH WALES.

190. As a result of conferences between representatives of the Association and of the South Wales and Monmouthshire Alliance of Friendly Societies in July, 1915, as to the possibility of an understanding being arrived at between the two bodies in connection with the various classes of medical aid organisations throughout the Kingdom, the A.R.M., 1915, resolved:—

Minute 121.—That it is inadvisable to take objection to the acceptance by members of the Association of appointments at those existing institutions in Wales and Monmouthshire recognised under Section 15 (4) of the Insurance Act which will conform to the following conditions:—

(a) Salaries or other forms of payment to be satisfactory to the Association;

(b) Free choice of doctor by patient and of patient by doctor to be allowed;

(c) The Institution doctor to be placed as nearly as

possible in the same conditions as the panel doctor as regards complaints by patients;

(d) The rules of the Institution, so far as they affect the doctor, to be approved by the Association, before any member is allowed to accept or retain appointment;

(e) Some guarantee to be obtained that the Institution is not using the Insurance Funds to finance the medical attendance on the dependants, thereby lowering the rate which the outside profession would be able to secure for the same work;

Minute 122.—Resolved: That the strongest opposition be offered to any extension of similar Institutions or Schemes, and especially to those Schemes formed in South Wales under Section 15 (3) of the Insurance Act.

The Association has now obtained from the Alliance, or direct, information as to the following Workmen's Medical Aid Institutions in South Wales:—Abertyswg, Blaenavon, Rhymney, Tredegar and Ebbw Vale.

In dealing with the matter the Council has also had regard to (i.) the following resolution of the A.R.M., 1913:—

Minute 141.—That the Representative Body adopt the following principles as essential to the formation of any schemes for the provision of medical attendance and treatment of uninsured persons:—

(1) That, in general, in considering the necessity for obtaining the approval of the Council for schemes for the treatment of uninsured persons upon contract terms, the following principles and conditions must be adhered to:—

(a) Free choice of doctor by patient, and of patient by doctor;

(b) Remuneration to be not less than that which is deemed by the Council to be equivalent to that paid in respect of insured persons—that is, 9s. per annum, including medicines;

(c) Persons with a total income from all sources of £104 per annum or upwards, or the dependants of any such person, not to be treated under contract terms at all.

(2) That the Representative Body realises that the conditions in certain areas will not allow of the above terms being obtained, and that in these circumstances the approval of the Council may be given provisionally to a scheme involving a less payment when the local profession can show that the economic conditions in the area demand it.

(3) That one of the conditions necessary for the approval of schemes containing lower rates of payment shall be the inclusion amongst the rules, in a prominent position, of a statement that approval by the Association has been given to the rates only because of special economic conditions;

and (ii.) the following rules adopted by the Council in January, 1915, in connection with the above *Minute 141* of the A.R.M. of 1913:—

(a) That no scheme or scale of charges be considered which is not submitted through a Division or Branch of the Association.

(b) That in all cases where schemes and terms for the provision of medical attendance and treatment of uninsured persons are approved by the (Medico-Political) Committee, the local Division must undertake to forward to the Central Office a copy of the final print of the rules (if any) or agreement, so as to enable the Committee to satisfy itself that its wishes in connection with such conditions have been embodied in the rules.

(c) That where any of the terms are lower than those approved by the Representative Body, there be included amongst the rules or in the agreement, in a prominent position, a statement that the terms mentioned had only been provisionally approved by the Association in view of the economic conditions of the area concerned to which the local profession had drawn attention, and

(d) That the Division concerned be asked to forward not later than eighteen months from its approval by the Association, a report upon the whole scheme.

The Council has come to the conclusion that none of the medical aid institutions which have submitted their rules, etc., conform to the terms laid down in *Minute 121* of the A.R.M., 1915.

PREVENTION OF TREATMENT OF VENEREAL DISEASES BY UNQUALIFIED PRACTITIONERS: VENEREAL DISEASE BILL OF THE GOVERNMENT.

(Continuation of para. 71, p. 89, of Annual Report.)

191. In connection with the Venereal Disease Bill of the Government, one clause of which was intended to prohibit the

sale of medicines, drugs and appliances for the treatment of venereal disease, except on prescription of a registered medical practitioner, the Council became aware that there was a possibility of objection being raised to the clause in the House of Commons by pharmacists, unless a quid pro quo was secured in the form of a provision prohibiting medical practitioners from dispensing. A conference was accordingly held between representatives of the Association and of the Pharmaceutical Society, with a view to an agreement whereby it would be possible to avoid the threatened opposition in Parliament. The representatives of the Society stated that while pharmacists as a body were in sympathy with the proposed legislation they felt that the clause in question would deprive pharmacists of a certain amount of business, e.g., the sale of various articles in demand by private customers, whereas the proposed legislation would not interfere with dispensing by medical practitioners, who, in fact, would probably dispense the identical articles which the pharmacists were to be prevented from selling. The representatives of the Society therefore urged that the two bodies should agree that no chemist should prescribe, and no practitioner dispense. On behalf of the Association it was pointed out that the position under the Bill would not be quite as stated, inasmuch as the treatment of venereal diseases in the case of patients of the industrial classes, hitherto given to a considerable extent by general practitioners, would largely go to the new State Clinics, and the early treatment of these diseases thus brought about meant, to the medical profession, a very considerable loss of income at present obtained from the treatment of the sequelae of these diseases; further, that the business which the pharmacists alleged they would lose under the Bill would in any event be lost to them in the near future, in that the treatment of venereal disease by ordinary internal medication was being superseded. It became apparent that an understanding could not be arrived at between pharmacists and the Association as to the clause.

Amendments having been tabled in the Commons at the instance of representatives of the pharmacists, the effect of which would have been to prevent medical practitioners from dispensing remedies for treatment of venereal disease, the views of the Association were placed before the members of the Standing Committee dealing with the Bill. The amendments were lost.

UNQUALIFIED PRACTITIONERS.

192. Arising out of information supplied by the Division of the Association primarily concerned, joint action taken by the Association and the Medical Defence Union against a person who kept a herbalist's shop, resulted in his being fined £25 and 10 guineas costs for using the titles "M.B." and "medical practitioner."

RECOGNITION OF BONE SETTERS.

193. A letter was sent to the Government in connection with the recent agitation in a section of the lay press and of Members of Parliament for utilisation of the services of a certain "manipulative surgeon" in the treatment of the wounded. The letter pointed out the logical consequences of such recognition by the State. The Council is glad to note that the Government has up to the present taken up a firm attitude on this question.

CENTRAL EMERGENCY FUND.

194. The following is an audited statement of the receipts and payments of the Central Emergency Fund for the year ending 31st December, 1916:—

Jan. 1st, 1916.		Dec. 31st, 1916.	
To Balance—	£ s. d.	By Grants	£ s. d.

„ Loan to British Medical Association ...	600 0 0	„ Do. Deposit ...	325 0 0
To Subscriptions and Donations from 1st January to 31st December ...	60 9 6	„ British Medical Association Loan Account ...	600 0 0
„ Interest ...	36 3 2		
	£1,040 2 0		£1,040 2 0

(I) National Health Insurance.

CONFERENCE OF REPRESENTATIVES OF LOCAL MEDICAL AND PANEL COMMITTEES.

195. Many important matters will require to be discussed with the Local Medical and Panel Committees before Insurance practitioners can be recommended to renew their agreements for 1918. In addition, it is important that the Association should receive renewed authority from the Local Medical and Panel Committees to continue to act as their representative in central negotiations. The Council therefore proposes to call, probably in October, a Conference of Representatives of the Local Medical and Panel Committees.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

(Continuation of para. 95, p. 92, and para. 1, p. 93, of Annual Report).

196. The Council arrived in April at the following provisional conclusions:—

(1) That the question of wounded disabled soldiers and sailors, whether insured or not, is one to be dealt with by the State as a special national problem outside the Insurance Acts.

(2) That in any scheme adopted for dealing with these men, it should be arranged (a) that for any discharged disabled soldier or sailor who becomes employed, and is therefore an insured person, a grant should be made to his Insurance practitioner from the Special Discharged Disabled Soldiers' and Sailors' Fund, to supplement the payment received under the Insurance Act; and (b), that for any discharged disabled soldier or sailor who remains unemployed and consequently not insured, an agreed annual payment should be made to a doctor of his own choice towards the cost of his domiciliary attendance.

(3) That it is preferable that these persons should be detained for treatment under military or naval discipline until such time as they are considered (i.) to be fit to earn their own living, or (ii.) as unlikely to benefit any further from treatment obtainable.

(4) That any financial arrangement put into operation by the State in connection with the treatment of wounded disabled soldiers and sailors, whether insured or not, should be retrospective, so as to bring within the scope thereof such soldiers and sailors as had already been discharged.

(5) That payment for medical attendance should be made for each person to the doctor attending him, on a scale agreed between the B.M.A. and the Government.

By instruction of the Council, these provisional decisions of the Council were considered by the Chairmen's, Hospitals, and Insurance Acts Committees jointly. The members of the three Committees met and discussed with Mr. George Barnes, M.P., the Pensions Minister, on May 15th, 1917, the question of medical attendance and treatment of discharged soldiers and sailors. (A report of the proceedings of the deputation was published in the *B.M.J.* Supplement of May 19th, 1917, p. 115.)

At this deputation to the Pensions Minister it was ascertained that the provision of general practitioner medical attendance and treatment had been handed over by the National Insurance (Part I. Amendment) Act to the Insurance Commissioners to carry out through the machinery of the Insurance Acts.

Subsequently, by invitation of the Commissioners, the Insurance Acts Committee resumed discussion of the subject with them on May 24th. The Committee agreed substantially to the proposals for new Regulations as to the treatment of discharged disabled soldiers and sailors who are not insured persons, but pressed again for adequate payment for the treatment of discharged disabled soldiers, both insured and non-insured. While failing to obtain any assurance that this request would be favourably considered by the Treasury, the Committee obtained an undertaking from the Commissioners that they would place its views before the Treasury. The Committee pressed that the same income limit (£160) as applied to voluntary contributors should apply also to discharged disabled men who were not insured persons, which view the Commissioners appeared to agree to, and also to the contention of the Committee that the new arrangements should not exclude practitioners who had hitherto abstained from Insurance practice from undertaking the treatment of discharged disabled soldiers and sailors.

To facilitate submission by the Commissioners to the Treasury of the views of the Insurance Acts Committee with regard to increased payment for treatment of discharged disabled soldiers and sailors, the Committee forwarded to the Commissioners the statement of the case of the medical profession for such increased payment. This was published in the *B.M.J.* Supplement of June 16th (see Appendix VIII).

It is understood that, as a result of the discussion between the Commissioners and Treasury, the latter is willing to agree to an arrangement whereby medical practitioners shall be paid on a per attendance basis for this treatment, the money being obtained from a pool made up of the 9s. at present available under the Insurance Acts, any excess of the doctors' accounts over the total of such pool being paid by the Treasury. This arrangement will apply automatically to all disabled soldiers and sailors who are discharged in the future, but as regards those who have already been discharged, as it is impossible to identify them individually, it will be optional to the doctor concerned to decide, when they present themselves for treat-

ment, whether he will retain any such persons on his capital list or treat them on the per attendance system. The proposals of the Commissioners on the subject are appended (see Appendix I¹).

FEDERATION OF LOCAL MEDICAL AND PANEL COMMITTEES.

197. The attention of the Council was drawn to the action of Local Medical and Panel Committee in circularising other Committees in its vicinity suggesting federation of those bodies. The Council has intimated that while it realises fully the desirability of communication between one Panel Committee and another, it is of opinion that such communication between individual Committees should be made direct, and not by any separate definite organisation or federation, a form of organisation which would only tend to divert the energies of the profession from the Insurance Acts Committee as the co-ordinating body.

NEW ADVISORY COMMITTEE.

(Continuation of para. 114, p. 95, of Annual Report.)

198. As a result of negotiations with Sir Edwin Cornwall, Chairman of the National Health Insurance Joint Committee, it has been arranged that the Statutory Advisory Committee under Section 58 of the 1911 Act shall consist of two Sections, viz. (a) General, (b) Medical, and that these Sections shall ordinarily meet separately to consider matters affecting primarily their respective interests. The General Section will consist of the present 30 members, together with 2 or 3 medical representatives nominated by the Medical Section from amongst their number. The Medical Section will consist of about 12 doctors, with one representative of institutions approved under Section 15 (4) of the Act, one or two chemists, and one or two members nominated by the General Section from their number. Of the 12 doctors, not less than 8, including one woman, must be actually engaged in practice under the Acts, and amongst the 8 there must be represented practice in the metropolitan area, rural areas, industrial areas, Scotland, Wales and Ireland. Of those not Insurance practitioners, it is intended that there shall be representatives of physicians, surgeons, pathologists and of the public health services, with one general practitioner not practising under the Acts.

Sir Edwin Cornwall has decided that the nominations for the Advisory Committee shall be obtained by the Insurance Acts Committee from the Local Medical Committees. Each of these has therefore been asked to nominate not more than 12 persons, who in its opinion would be most capable of representing the views of the profession on the Advisory Committee, and who would among them comprise the various types of practice mentioned. Obviously, as regards the 4 who are not Insurance practitioners, it will require the exercise of considerable judgment to combine the various types of practice, in the persons of four practitioners. When the nominations are received, the Insurance Acts Committee will select from amongst them (bearing in mind the above points, and guided by the preferences shown by the nominations) names which it will forward to Sir Edwin Cornwall, who will make the appointments.

MEDICAL PROFESSION AND FUTURE OF INSURANCE PRACTICE.

(Continuation of para. 104, p. 93, of Annual Report.)

199. A large amount of information has now been received from all over the Kingdom in response to the Memorandum and Questions issued by the Insurance Acts Committee (D. 8.9. See *B.M.J.* Supplement, January 12th, 1917). In the light of the information thus obtained, the Committee has prepared an Interim Report (D. 19) setting forth the views of the profession, and has issued it, with a series of questions in respect of the various proposals therein suggested (D. 18), to Chairmen and Secretaries of Divisions and Local Medical and Panel Committees and Presidents and Secretaries of Branches. Both documents appeared in the *B.M.J.* Supplements of June 23rd and 30th, 1917. After the replies are received to the questions, it is the intention of the Council to draft a final report, with a view to its becoming the declared policy of the Association.

METHOD OF ORGANISATION OF PROFESSION.

(Continuation of paras. 131-2, p. 97, of Annual Report.)

200. The Council has prepared and issued to Insurance practitioners the first of its Quarterly Circulars stating the work of the Association on their behalf.

PAYMENTS TO MEDICAL AID INSTITUTIONS FOR PROVISION OF MEDICAL ATTENDANCE AND TREATMENT OF INSURED MEMBERS.

201. The Council has considered the question of the favoured treatment received by medical aid institutions in some parts of

the country as regards the payments in respect of the medical attendance and treatment of their insured members. The Council cannot admit that medical aid institutions should be placed in a more favoured position, as compared with medical practitioners, in the matter of deductions from their lists of members owing to inflation, nor (though there may be a case for an Insurance Committee exercising its discretion as to the deduction owing to inflation of lists as between institutions in its area) can it admit that an Insurance Committee is given any discretion by the Regulations in the matter of inflation of lists as between institutions and medical practitioners. The Council has further expressed the opinion as regards the argument that institutions are entitled to favourable consideration in the matter of deductions for inflation because they have no share in the unallotted money shared by the medical practitioners, that it must be remembered that institutions are not under the liability, which Insurance practitioners are under, to attend unallotted insured persons, nor are the former likely to have assigned to them any unallotted insured persons to whom they might refuse membership, as in practically every area there exists a scheme under which medical practitioners have agreed to take such unassigned insured persons.

CENTRAL INSURANCE DEFENCE FUND.

(Continuation of para. 134, p. 97, of Annual Report.)

202. The Council submits a statement of the receipts and payments in 1916 of the Administration and Compensation Accounts of the Central Insurance Defence Fund, together with a statement of the available funds as at December 31st of that year (see Appendix X).

Non-Panel Committee

MEMBERSHIP OF COMMITTEE.

(Continuation of para. 135, p. 97, of Annual Report.)

203. The Council has authorised the Non-Panel Committee to co-opt not more than 5 further members.

MEDICAL ATTENDANCE AND TREATMENT OF INDUSTRIAL AND POORER CLASSES.

204. The Council has endorsed the following opinions of the Committee and submits them for the consideration of the Representative Body:—

Recommendation A.—That the medical treatment of the industrial and poorer classes should not be carried out by a whole-time salaried State Medical Service.

Recommendation B.—That the medical treatment of the industrial and poorer classes, which there is reason to believe is intended by the Government, should be carried out by a modified or improved Insurance Scheme.

Recommendation C.—That no system of State-controlled Medical Service will be acceptable to those medical practitioners who are not giving service on the present Panel System which does not provide (a) complete and efficient medical and surgical treatment to that section of the community which is unable to provide such treatment for itself, and (b) freedom to any other person involved in any system of State Medical Service to make his own individual arrangements for treatment if he so desire.

(J) Public Health and Poor Law.

UNIFORM FORM FOR NOTIFICATION OF INFECTIOUS DISEASE.

(Continuation of para. 136, p. 97, of Annual Report.)

205. Further correspondence has passed with the Local Government Board as to a uniform form for notification of infectious disease. The Council gathers that the proposed form will be issued shortly.

ASSOCIATION OF POOR LAW AUTHORITIES WITH MATERNITY AND CHILD WELFARE CENTRES.

206. There appears to be a desire on the part of some few local authorities to make use of Poor Law funds in connection with the work carried on at Maternity and Child Welfare Centres. This tendency should in the opinion of the Council be combated.

The Council recommends:

Recommendation.—That the grants for nutriment and such like provided for young children by Maternity and Child Welfare Centres should not be made from Poor Law funds.

CO-OPERATION BETWEEN ASSOCIATION, POOR LAW MEDICAL OFFICERS, AND MEDICAL OFFICERS OF HEALTH.

(Continuation of para. 137, p. 97, of Annual Report.)

207. Meetings of the newly appointed Poor Law Medical Officers and Medical Officers of Health Sub-Committees have been held, and have been found most helpful.

PERMANENT APPOINTMENTS OF MEDICAL OFFICERS OF HEALTH DURING THE WAR.

208. Representations are being made to the Local Government Board as to its apparent acquiescence in recent permanent appointments of whole-time medical officers, notwithstanding its circular letter of May, 1915, which urged local authorities not to make such permanent appointments during the War.

PUBLIC HEALTH AND POOR LAW APPOINTMENTS.

(Continuation of para. 138, p. 97, of Annual Report.)

209. Successful action has been taken in further cases of public health and Poor Law appointments.

(K) Hospitals.

FUTURE POSITION OF VOLUNTARY HOSPITALS: DISCHARGED DISABLED SOLDIERS AND SAILORS.

(Continuation of para. 140, p. 97, of Annual Report.)

210. In the report of the proceedings of the Deputation to the Minister of Pensions (Supplement May 19th, 1917, p. 115) will be seen the provision made and intended to be made by the Government for institutional treatment. In this connection the Pensions Minister, as a result of the views expressed by the Association's representatives at the Deputation, suggested that a Medical Advisory Committee should be set up, and invited the Association to appoint representatives thereon. The Council appointed Dr. H. B. Brackenbury, Mr. N. Bishop Harman and the Medical Secretary. The other members are Sir Frederick Taylor, Bart., Dr. Sidney Martin, Sir W. Watson Cheyne, Bart., and Sir J. Rickman Godlee, Bart.

The Advisory Committee has already held one meeting, at which Mr. Barnes asked its opinion on a draft instruction proposed to be issued to all Pensions Committees, stating the way in which discharged men should be enabled to secure such specialist treatment as they require. A discussion arose on the terms proposed to be paid to Voluntary Hospitals for the maintenance of such men as become in-patients. The representatives of the Association urged that the sum paid should include a proportion to be ear-marked for payment of the medical staff for the work done, in accordance with the policy of the Association, but as there was a difference of opinion on the matter the present proposal of the Ministry is to leave the matter to be settled by the individual hospitals and their staffs. Since that time a meeting of the members of the Advisory Committee has been held, and the Council is glad to report that unanimity has been reached in consequence of which representations have been made to the Minister in favour of the policy of the Association.

(L) Scotland.

SCOTTISH SUB-COMMITTEE OF INSURANCE ACTS COMMITTEE.

(Continuation of para. 145, p. 98, of Annual Report.)

211. The Scottish Committee is obtaining, in co-operation with the Insurance Acts Committee, the nomination by Scottish Panel Committees of practitioners for appointment upon the Scottish Sub-Committee of the Insurance Acts Committee. It has been decided that before the Meeting of the next Conference of Local Medical and Panel Committees convened by the Association, the Sub-Committee shall meet and consider the Agenda of the Conference.

QUESTION OF INCREASE OF MEDICAL FEES.

(Continuation of para. 150 (1), p. 99, of Annual Report.)

212. The Scottish Committee has considered the replies received from a number of the Divisions to a circular issued by the Committee, enquiring whether they have recently passed any resolutions as to the general raising of professional charges. As some Divisions have not yet replied, consideration of the question of the desirability of taking steps in the matter has been postponed until the next Meeting of the Committee.

CENTRAL MIDWIVES' BOARD (SCOTLAND).

(Continuation of para. 150 (3), p. 99, of Annual Report.)

213. Drs. Michael Dewar (Edinburgh) and J. Wishart Kerr (Glasgow), members of the Scottish Midwives Board appointed by the Scottish Committee, have submitted a very satisfactory report upon the work of the Board for the past year, and they have been thanked for their services.

(M) Ireland.

ACTIVITIES OF THE IRISH COMMITTEE.

214. The Council is glad to note the increased activity of the Association in Ireland. Since the publication of the Annual Report the Irish Committee of the Association has held another Meeting at which many points of interest to the Irish profession were discussed, and various steps taken to bring before Government Departments the claims of the profession

in connection with the Notification of Births, etc. and certain Poor Law matters.

It is a source of gratification to the Council to note the increasing use that is being made of the Irish Office of the Association and the Irish Medical Secretary in connection with practically every form of medico-political activity in the Country.

(O) Naval and Military.

PRESENT POSITION AND FUTURE PROSPECTS OF INDIAN MEDICAL SERVICE.

215. As reported to the Divisions in 1914 (Annual Report of Council, *B.M.J.* Supplement, May 2nd, 1914, p. 290, para. 172), the Council in 1913 forwarded to the Secretary of State for India a Memorandum upon the position and prospects of the Indian Medical Service (see *British Medical Journal*, March 7th, 1914), in response to a letter from the Secretary of State intimating that he would be glad of the assistance of the Association in ascertaining the cause of the deficiency of high-class candidates for that service. Subsequently, in response to an invitation received from the Royal Commission on Public Services in India, the Council in 1914 appointed Lieut.-Col. R. H. Elliott, I.M.S., to give evidence on behalf of the Association before the Commission.

The Council regrets to have to record its profound concern and disappointment with the whole trend of the Report and Recommendations of the Commission, published in January, 1917, so far as regards the Indian Medical Service, and is of opinion that the matter cannot be left where it stands. The Council submits a Memorandum on the subject (see Appendix XI.), and in the event of the Memorandum being approved by the Representative Body, it is intended to ask the Secretary of State for India to receive a deputation, to be appointed by the Naval and Military Committee of the Association, for the purpose of discussing with him the position of the Indian Medical Service.

The Council recommends:

Recommendation A.—That the Representative Body approve the Memorandum submitted by the Council, on that part of the Report of the Royal Commission on the Public Services in India which deals with the Indian Medical Service.

NOMINATIONS FOR ELECTION OF REPRESENTATIVES OF SERVICES AS MEMBERS OF COUNCIL.

Recommendation B.—That the following representatives of the Services on the Council be appointed for the period 1917-20:—(a) For the Royal Navy Medical Service, Fleet-Surg. F. D. Lumley, R.N. (Retd.); (b) For the Army Medical Service, Col. R. I. D. Hackett, A.M.S. (Retd.); (c) For the Indian Medical Service, Lt.-Col. R. H. Elliott, I.M.S. (Retd.).

DEPARTMENTAL COMMITTEE OF ENQUIRY INTO ANOMALIES OF PROMOTION, ETC., OF OFFICERS OF THE TERRITORIAL FORCE AND NEW ARMIES.

216. In view of the appointment by the Government of a Departmental Committee to enquire into the anomalies of promotion of Officers of the Territorial Force and New Armies, there were submitted to the Departmental Committee, on behalf of the Association, the Memorandums (see Appendix XII.), based upon a considerable amount of correspondence and interviews with Medical Officers of the Territorial Forces, published in the SUPPLEMENTS of March 17th and May 19th.

The Association pressed upon the Departmental Committee that it should be allowed to support the Memorandums by oral evidence, and selected three witnesses for the purpose. The Departmental Committee however intimated that it could only hear one witness on behalf of the Association. Accordingly Col. J. Raglan Thomas, accompanied by the Deputy Medical Secretary, gave evidence before the Departmental Committee on June 13th, 1917, when the suggestions of the Association were fully discussed. The report of the Committee must now be awaited before further action can be taken.

J. A. MACDONALD,
Chairman of Council.

July 3rd, 1917.

The Annual Report of the Council had seven appendices, numbered I to VII, the Supplementary Report has five, numbered VIII to XII.

Appendix VIII, containing the case of the profession for increased payment for treatment of discharged disabled soldiers and sailors, was published in the SUPPLEMENT of June 16th, 1917, p. 159.

Appendix IX, containing the proposals of the National Insurance Commissioners as to the remuneration of doctors in respect of invalided sailors and soldiers, is published below.

Appendix X, a statement of accounts of the Central Insurance Defence Fund, is published below.

Appendix XI is a memorandum on the Indian Medical Service, and is published below.

Appendix XII consists of memorandums by the Association on anomalies as to promotion of officers of the Territorial Forces and new armies; they were published in the SUPPLEMENTS of March 17th, 1917, p. 49, and May 19th, 1917, p. 116.

APPENDIX IX.

PROPOSALS OF NATIONAL HEALTH INSURANCE COMMISSIONERS AS TO REMUNERATION OF DOCTORS IN RESPECT OF INVALIDED SAILORS AND SOLDIERS.

(Document furnished by Insurance Commissioners).

(See page 6, para. 196, of Supplementary Report of Council.)

1. The proposal is that doctors should be remunerated in respect of discharged disabled sailors and soldiers on the attendance basis at the same rates as temporary residents, on the assumption that, if the total payments to be made are in excess of a sum calculated at the rate of 9s. per discharged disabled man the amount of the excess will be found by the Exchequer.

2. The foregoing proposal necessarily involves the appropriation from the General Medical Benefit Fund of the sum of 9s. for each invalided man towards the cost of treatment of all such persons. Certain considerations arise in this connection which may be conveniently dealt with under two heads, viz. :—

- (a) Future invalidings, and
- (b) Past invalidings.

3. With regard to (a), as each case arises steps will be taken to put the man forthwith under the new arrangements, and the 9s. can be appropriated there and then. No difficulty thus arises with this class.

4. With regard, however, to (b), it must be remembered that most of these men are already included in the doctors' lists. Obviously, every man in respect of whom nine shillings is appropriated should be removed from the doctor's list. But although the number of such men in the aggregate is known, and therefore the number of sums of nine shillings to be appropriated, no record is available of their names or distribution amongst doctors.

5. Were it possible for the doctors, with such assistance as Insurance Committees can afford, to pick out *all* past invalided sailors and soldiers included in their lists, the difficulty could thus be solved. But it is understood that this plan is not feasible; and it is necessary, therefore, to consider alternative proposals.

6. One practical method would be to deduct from the General Medical Fund the total number of sums of nine shillings to be appropriated (which, as indicated above, is ascertainable by the Commissioners) without amending the doctors' lists. The effect of this operation would be to increase the inflation in the doctors' lists. If each doctor had in his list the same proportion of invalided men, no inequity would result. This, however, is not the case. For example, the woman doctor would probably not have any invalided men in her list and would therefore be prejudiced.

7. It might be possible to obviate the inequity in its acutest form by the following plan. Having ascertained the total sum to be appropriated for the whole country, the central pool would not be diminished; but the amount to be appropriated in respect of men hitherto invalided would be apportioned among the several areas on the basis of the proportionate number of men found in fact to be invalided in future in each area, so as to arrive at an amount to be debited to the *local* pool of each area. It would then be possible for the Insurance Committee and Panel Committee in each area to arrange for the apportionment of this debit among the doctors in the area, excluding, if they thought it desirable, the woman doctor and any other doctor who could prove that he had no invalided men on his list. This would involve the introduction of an additional and somewhat complicated piece of machinery.

8. Alternatively, perhaps, it might be possible for past invalidings to be brought under the new arrangements gradually, so that part of the invalided men already on doctors' lists would be dealt with on the attendance basis and part on the capitation basis. It would be necessary in this event to secure that the Exchequer is safeguarded against the possibility of an unfair selection of cases being made by the doctors. Perhaps this might be secured by an arrangement on the following lines

9. Until any particular invalided soldier is brought under the new arrangement, the nine shillings will accrue to the General Medical Benefit Fund in respect of him, and the doctor will be remunerated in the ordinary way. It will be open to the doctor at any time to claim that he should be remunerated in respect of the soldier on the attendance basis. It will be obvious, however, that payment could not be made forthwith

on the attendance basis since, if this were done, the doctor would in practice be paid on the capitation basis whilst the patient was well, and on the attendance basis after he fell ill, which is clearly not an insurance proposition. It would be necessary, therefore, to impose a waiting period after the doctor's claim. This period need not be long, and the Treasury might consider that they have a sufficient safeguard if the case be included under the new arrangements as from the beginning of the quarter succeeding that in which the doctor's claim is made. The doctor will, of course, continue to be remunerated on the ordinary basis until that date. It will be appreciated that under this method each doctor would have an option (as regards each invalided man already on his list) as to whether he will continue to be remunerated on the capitation basis or will change over to the attendance basis as from the commencement of the ensuing quarter.

APPENDIX X.

STATEMENT OF RECEIPTS AND PAYMENTS OF CENTRAL INSURANCE DEFENCE FUND IN 1916, AND OF AVAILABLE FUNDS AS AT DECEMBER 31st, 1916.

(See page 7, para. 202, of Supplementary Report of Council.)

ADMINISTRATION ACCOUNT.

APPENDIX XI.

MEMORANDUM OF THAT PART OF REPORT OF ROYAL COMMISSION ON PUBLIC SERVICES IN INDIA WHICH DEALS WITH INDIAN MEDICAL SERVICE.

(See page 8, para. 215, of Supplementary Report of Council.)

The British Medical Association has carefully considered that part of the Report (published in January, 1917) of the Royal Commission on the Public Services in India which deals with the Indian Medical Service, and regrets to have to record its profound concern and disappointment with the whole trend of the Report and its Recommendations.

The various points to which the Association drew attention in its Memorandum on the Present Position and Future Prospects of the Indian Medical Service have received very scanty attention, and there is little or no evidence of any intention to redress the numerous grievances which the Association pointed out could not fail, if allowed to continue, to result in a marked deterioration in a service already becoming unpopular.

COMPARISON OF REPORT OF COMMISSION AND THE MORE IMPORTANT RECOMMENDATIONS OF THE ASSOCIATION.

Entrance Examinations.

1. That the present method of recruitment for the Indian Medical Service by competitive examinations held in England should be continued; that the examination should be kept as practical as possible rather than theoretical; and that the importance of this aspect of the question should be brought prominently before the attention of the examiners.

R.M.A.
Memo.

Royal Commission Agrees and Recommends: That the open competitive examination for the Indian Medical Service should be made more practical, and a *vivâ voce* test should be introduced. All candidates should have had a hospital training, have been through a practical course of midwifery; and have had experience of treating the diseases of women and children. If it is found necessary to give Indians this training in the United Kingdom sufficient facilities should be provided there for them.

Training in a British School of Medicine.

B.M.A. Memo. 2. That candidates from India should be encouraged to spend as much time as possible in a British School of Medicine. A period of three years would be none too long to permit a man to become acquainted with the methods of sanitation, the modes of living, hospital treatment and dietary, and the other features of medical practice which are so widely different in Europe and India.

Royal Commission Ignores, with the exception of the above half-hearted and vague recommendation.

Post-graduate Training.

B.M.A. Memo. 3. That the time now spent at Millbank would be better spent in the large hospitals and schools of medicine in the Indian Presidency towns, where a course of study of tropical diseases, bacteriology, and hygiene could be carried out under ideal conditions. Larger facilities should be afforded to medical officers for taking up resident appointments before going out to the East.

Royal Commission Ignores.

Too Frequent Transfers.

B.M.A. Memo. 4. That Officers are subjected to too frequent transfers.

Royal Commission Ignores.

Allowances on Transfer.

B.M.A. Memo. 5. Reasonable cost of transfers should be provided by Government instead of the present entirely inadequate allowances.

Royal Commission Agrees and recommends: That the principle that travelling expenses must not be treated as a source of profit has its necessary corollary in the principle that such expenses should not be a source of loss. Exactly what provision should be made to meet such charges is a question for the decision of Government. We would, however, urge that immediate measures be taken to remove what undoubtedly is a widespread and, in our opinion, a legitimate grievance.

Family Pensions Fund.

B.M.A. Memo. 6. (a) That pensions for sons should continue up to the age of 25.

(b) That daughters who have become widows should be again eligible for pensions.

Royal Commission Ignores.

Leave.

B.M.A. Memo. 7. That an officer should be allowed to take the leave due to him, and to take it when it falls due, instead of having, as too often happens at present, to forego it for long periods, or else to "go sick."

Royal Commission Agrees and recommends: That the reserves for leave, deputation, and training in the various civil medical services should be re-calculated. In the local services more uniformity should be observed in making the calculations, and, where possible, an annual rate of recruitment should be fixed.

B.M.A. Memo. 8. That a more liberal grant of casual leave should be made, and the disposal of all matters connected with this form of leave should lie entirely in the hands of the local Surgeon-General.

Royal Commission Ignores.

The Right of Private Practice.

B.M.A. Memo. 9. That all interference with the right of private practice and fees should be withdrawn.

Royal Commission Recommends: (a) Civil surgeons, and officers holding similar posts, whether belonging to the Indian Medical Service or not, and the assistant surgeons working under them, should enjoy the privilege of private practice at the pleasure of Government. Should it be found necessary to withdraw this privilege in individual cases a suitable monthly allowance should be granted.

(b) Medical Officers holding scientific posts should be debarred from private practice but should receive a monthly allowance instead. Similar officers holding clinical posts should be allowed consulting practice in their own subject. Chemical examiners and alienists and their assistants should be allowed private practice, under certain conditions, but only in their own subject, and in such cases the fees should be credited to Government and a suitable monthly allowance made to the officer concerned.

Provincial Medical Service.

10. That a Provincial Medical Service should be created on lines similar to those of the Provincial Civil Service.

Agrees.

Royal Commission

Period on Probation.

11. That the period spent on probation, and the time from completing the period of probation until arrival in India should in the case of all officers count towards an officer's service for promotion.

Ignores.

Royal Commission

The Position of the Surgeons-General.

12. That the Surgeon-General should be a Secretary to Government, and the personal assistant to a Surgeon-General an Under Secretary to Government in the Medical and Sanitary Departments, both being paid as such.

Opposes this and recommends: The Surgeon-General and the Inspectors-General of civil hospitals should have regular and direct access to the head of their province, or to the member of council in charge of the medical department, where there is a council form of Government.

Royal Commission

Status of District Medical Officer.

13. That the district medical and sanitary officer of a district should, in the interests of discipline and efficiency, have complete control over his medical subordinates, including vaccinators, as regards transfers from one station to another within the district.

Ignores.

Royal Commission

Confidential Reports.

14. That it should not be open to any lay authority to override or disregard the Surgeon-General's opinion on professional matters.

Ignores.

Royal Commission

Conclusion.

15. The Association does not attempt to dictate to the Government of India the terms that it should offer to its medical officers, but, knowing as it does the feeling of the medical profession, it desires to make it clear to the Under-Secretary of State for India that a failure to redress the grievances which the Association has pointed out, will most certainly result in a very marked augmentation of the deterioration already in progress in the class of recruits to the I.M.S.

16. The Association feels that the real storm-centre is the question of limiting private practice of Indian Medical Service officers. It desires that there should be no ambiguity in future as to the policy to be adopted by the Secretary of State for India on this subject, in order that it may be in a position to place the future prospects of officers of this Service clearly before the profession, and to give such advice on the subject to possible applicants as they are entitled to expect from it.

Association Notices.

ANNUAL REPRESENTATIVE MEETING, 1917

Date of Meeting.

The Annual Representative Meeting of the Association will be held at the Connaught Rooms, Great Queen Street, London, W.C., on Thursday, July 26th, at 10 a.m. and following day(s) as may be required.

Agenda of A.R.M.: Further Notices of Motion by Divisions and Branches.

The provisional Agenda of the Annual Representative Meeting, including the Annual Report of the Council, was

published in the SUPPLEMENT of May 5th, and a supplementary Notice of Motion in the SUPPLEMENT of June 2nd. The Supplementary Report of the Council is published in this SUPPLEMENT. There will be included in the final Agenda of the Meeting, as to be issued to the members of the Representative Body on or about July 19th, not only the Notices of Motion published in the SUPPLEMENTS of May 5th, June 2nd, and (Supplementary Report of Council) July 7th, but also Notices of Motion received up to Thursday, July 12th, found by the Agenda Committee to be in order.

By order,

ALFRED COX,

Medical Secretary.

July 4th, 1917.

ANNUAL GENERAL MEETING.

NOTICE is hereby given by the Council that the Annual General Meeting of the British Medical Association will be held at the Connaught Rooms, Great Queen Street, London, W.C., on Friday, July 27th, 1917, at 2 o'clock in the afternoon. *Business:* (1) Minutes of last meeting. (2) Appointment of auditors (Messrs. Price, Waterhouse, and Co. offer themselves for re-election). (3) Award of Middlemore Prize. (4) Report election of President.

By Order,

GUY ELLISTON,

Financial Secretary and Business Manager.

Dated this 7th day of July, 1917.

429, Strand, London, W.C.2.

BRANCH AND DIVISION MEETINGS TO BE HELD.

EAST ANGLIAN BRANCH.—Dr. B. H. Nicholson, Honorary Secretary (East Lodge, Colchester), gives notice that the annual meeting of the East Anglian Branch will be held at the Crown and Anchor Hotel, Ipswich, on Tuesday, July 10th, at 3 o'clock.

EAST YORKS AND NORTH LINCOLN BRANCH.—Mr. H. L. Evans, Honorary Secretary (101, Princes Avenue, Hull), gives notice that the annual meeting of the Branch will be held in the Board Room of the Hull Royal Infirmary, at 4 p.m., on Friday, July 13th. *Business:* Annual report, financial statement, election of officers. Address by Robert Grieve, M.D., F.R.C.S.

SOUTHERN BRANCH.—Mr. James Green, Honorary Secretary, gives notice that the annual meeting of the Branch will be held at the South-Western Hotel, Southampton, on Thursday, July 12th, at 3 p.m., Dr. A. E. Bodington in the chair. *Business:* Minutes. Correspondence. Election of officers for 1917-18. Annual report. Balance sheet. To consider resolution of Branch Council: "That it be recommended from this Council to the next general meeting that the future quorum of the Council consist of five members." General business. At the conclusion of the business Dr. Bodington will vacate the chair in favour of the incoming president, Dr. H. J. May of Southampton. On account of the war there will be no luncheon or other social function, except that tea will be served at the end of the meeting by the kindness of Dr. May. The usual collection for Epsom College will be made during tea time. There will be no golf competition this year. Members who intend to accept the President's invitation to tea will oblige by sending word to that effect not later than July 9th to Mr. C. P. le Quesne, 1, Lawn Road, Southampton.

SOUTH MIDLAND BRANCH: BUCKINGHAMSHIRE DIVISION.—Dr. Arthur E. Larking (Secretary) gives notice that a meeting of the members of the Bucks Division, to which all medical men in the county are invited, will be held at the Crown Hotel, Aylesbury, on Thursday, July 19th, at 2.45 p.m., to re-elect the Local Medical War Committee, discuss the question of the formation of a Ministry of Health, consider matters relating to payments under the National Insurance Act, and other matters. Tea will be provided.

Meetings of Branches and Divisions.

FIFE BRANCH.

The annual meeting of the Fife Branch was held at Kirkcaldy on June 6th, when Dr. Macdonald was in the chair.

Annual Report.—The annual report and balance sheet were passed.

Election of Officers.—The following officers were elected:

President: Dr. John Macdonald (Cupar). *Vice-President-elect:* Dr. Wm. Craig (Cowdenbeath).

PROCEEDINGS OF COUNCIL.

A MEETING of the Council was held in London on June 27th, 1917, and there were present:

Dr. J. A. Macdonald, LL.D., Chairman of Council, presiding; Sir T. Clifford Allbutt, Mr. E. B. Turner, Dr. G. E. Haslip, Dr. John Adams, Surgeon-General P. H. Benson, Dr. M. G. Biggs, Lieut.-Colonel R. A. Bolam, Dr. H. B. Brackenbury, Dr. Francis Clark, Major Russell Coombe, Dr. J. Singleton Darling, Dr. Edward J. Domville, Captain E. Rowland Fothergill, Dr. Adam Fulton, Dr. T. W. H. Garstang, Dr. James Green, Mr. N. Bishop Harman, Lieut.-Colonel W. T. Hayward, C.M.G., Dr. I. W. Johnson, Major Albert Lucas, Dr. H. C. Mactier, Colonel C. H. Milburn, Dr. E. N. Nason, Major George Parker, Dr. Edwin Rayner, Dr. C. E. Robertson, Dr. F. J. Smith, Dr. W. Johnson Smyth, Dr. John Stevens, Dr. T. Jenner Verrall, LL.D., Dr. Claude Wilson, and Dr. O. R. M. Wood.

Sir James Barr, Dr. H. J. Campbell, Major A. C. Farquharson, Dr. J. Giusani, Dr. John Gordon, Major T. D. Greenlees, Major J. Livingstone London, Fleet Surgeon F. D. Lumley, R.N., and Lieut.-Colonel J. Munro Moir sent letters of apology regretting unavoidable absence.

DEATHS.

The Council passed votes of condolence on the deaths of Dr. Henry Hetley, of Norwood, a former member of Council; Dr. Major Greenwood, a member of Council at the time of his death; Dr. J. Mitford Atkinson, a former representative of the Hong Kong and Malaya Group of Branches; Inspector-General Robert Bentham, R.N., at one time representative of the Royal Navy Medical Service; and Lieut.-Colonel Davie Harris, a former representative of the R.A.M.C.

HONOURS TO MEMBERS OF COUNCIL.

The CHAIRMAN, on behalf of the Council, congratulated Colonel James Galloway, A.M.S., and Lieut.-Colonel W. T. Hayward on the honours recently conferred upon them by H.M. the King.

MEDICAL EXAMINATIONS OF DISCHARGED SOLDIERS AND MEDICALLY REJECTED MEN.

The CHAIRMAN of Council drew attention to the appointment by the House of Commons of the Select Committee on medical examination under the Review of Exceptions Act, and to the severe criticisms in the lay press and by members of the House of Commons upon members of medical boards in connexion with the medical examination of recruits for the army, and suggested that the Council should consider the desirability of action being taken by the Association on behalf of members of the profession in connexion therewith. A Special Committee was appointed to watch the proceedings of the Select Committee, and to take any action it may deem advisable in the interests of the profession in connexion therewith. The Committee consists of the Chairman of Council, the Chairman of Representative Meetings, the Treasurer, Dr. T. Jenner Verrall, Dr. M. G. Biggs, and Major Russell Coombe, with power to co-opt.

A communication from Mr. Ben Tillett, General Secretary, Dock, Wharf, Riverside, and General Workers' Union

of Great Britain and Ireland, forwarding for the consideration of the Association a resolution passed at the triennial meeting of that union, protesting against the action of medical boards in passing unfit men into the army, was referred to this committee.

UNIVERSITY OF WALES.

The CHAIRMAN reported that he had renominated Dr. Ewen J. Maclean as Representative of the British Medical Association on the Medical Board of the University of Wales for a further period.

FINANCE COMMITTEE.

ACCOUNTS.

The accounts for the period ending June 2nd, 1917, amounting to £11,484 9s. 1d., were received and approved, and the Treasurer was empowered to pay those still outstanding.

MEDICO-POLITICAL COMMITTEE.

HANDBOOK OF THE ASSOCIATION.

The Council expressed the opinion that the more important decisions of the Association upon matters of policy, together with essential general information as to the Association, should be collated and issued for the information and use of Secretaries of Divisions and Branches and others. This expression of opinion was referred to the Organization Committee, which will report as to the practicability and probable cost of such action.

ARTICLES AND BY-LAWS CONCERNING HOLDING OF ANNUAL REPRESENTATIVE MEETING.

The Organization Committee was instructed to consider and report as to the advisability of the Association, through the Council, obtaining powers to alter the Articles of Association which compel the holding of the Annual Representative Meeting.

CANDIDATES.

Eighteen candidates were elected members of the British Medical Association.

The rest of the proceedings of the Council were incorporated in the Supplementary Report of Council published in the SUPPLEMENT of last week (p. 2 et seq.).

Meetings of Branches and Divisions.

EDINBURGH BRANCH.

The annual summer meeting of the Edinburgh Branch was held in the Hall of the Royal College of Physicians, Edinburgh, on June 20th.

Vote of Condolence.—The PRESIDENT made sympathetic reference to the death, in the service of their country, of Dr. W. Guthrie Porter, Edinburgh, and of Dr. W. H. Calvert, a former member of the South-Eastern Counties Division, and a vote of condolence with their relatives was passed.

Annual Report and Financial Statement.—The report of the Branch Council was submitted and approved. The HONORARY TREASURER submitted the annual financial statement, showing a credit balance, on December 31st,

1916, of £50 15s. 10d.; he was cordially thanked for his services.

Election of Officers.—The following office-bearers were elected for 1917-18:

President: Dr. William Blair. *President-elect:* Dr. R. McKenzie Johnston. *Vice-Presidents:* Drs. W. R. Martine, J. J. Graham Brown.

Honorary Treasurer: Dr. R. A. Lundie.

Honorary Secretaries: Dr. John Stevens, Captain John Eason.

Vote of Thanks to Retiring President.—In the unavoidable absence of Dr. Blair, the chair was then taken by Dr. MARTINE. Dr. James Ritchie, on vacating the chair, was cordially thanked for his services as President during the past year.

Representative on the Central Council.—It was intimated that Dr. John Stevens had been re-elected Representative on the Council of the Association for the Edinburgh and Fife Branches.

Queen Mary Nursing Home.—Dr. Alexander Scott (Broxburn) was elected to fill the annual vacancy on the Board of Management of the Queen Mary Nursing Home.

Scottish Committee.—The proceedings of the Scottish Committee were reported on, including the formation (now in progress) of an Insurance Acts Subcommittee for Scotland, and the arrangements for co-operation between the Scottish Committee and the Colliery and Public Works Surgeons' Committee.

Scottish Medical Service Emergency Committee.—A statement was made of the work of the Scottish Medical Service Emergency Committee, showing that throughout Scotland, the Edinburgh Branch included, the response to the call for medical officers for the R.A.M.C. continues, notwithstanding the seriously depleted state of the profession, to be all that can be desired, and that Scotland is still giving its full share towards the requirements of the army.

Annual Report of Central Council.—On the Annual Report of Council the following resolutions were carried unanimously:

I. Ministry of Health.

That, while welcoming the appointment of a Ministry of Health, this meeting is of opinion that the scheme for giving effect to this requires very careful consideration, and is strongly of opinion that the circumstances under which the profession is at present placed make it impossible effectively to consider any scheme before the end of the war, and it therefore cannot give its support at this time to the scheme proposed by the Council of the Association, and very strongly protests against a provisional scheme having been forwarded by the Council of the Association to the Government on the plea of urgency.

II. Provision of Medical Treatment for Discharged Disabled Soldiers and Sailors.

1. That any provision made for medical attendance on discharged disabled soldiers and sailors ought to be outside the National Insurance Acts.
2. That this provision ought to be made under conditions which will allow of these persons being attended by any registered medical practitioner they may respectively choose.

METROPOLITAN COUNTIES BRANCH.

THE sixty-fifth annual general meeting of the Branch was held at 429, Strand, W.C., on June 26th, when the President, Surgeon-Colonel ATWOOD THORNE, was in the chair.

Election of Officers.—The following officers were elected for 1917-18:

President: Dr. C. O. Hawthorne. *President-elect:* Dr. M. G. Biggs. *Past President:* Surgeon-Colonel Atwood Thorne, V.D., R.A.M.C.(T.). *Vice-Presidents:* Dr. Cecil W. Cunningham, Dr. G. Michael, Dr. H. H. Norton, Dr. H. Tanner.

Honorary Treasurer: Mr. H. Betham Robinson, M.S., F.R.C.S.

Honorary Secretaries: Mr. N. Bishop Harman, M.B., F.R.C.S., Dr. Wilfred Kingdon, R.A.M.C.

Representatives of the Branch on the Central Council of the Association:—Elected by the Metropolitan Counties Branch: Dr. M. G. Biggs, Dr. H. B. Brackenbury, Colonel James Galloway, C.B., A.M.S., Dr. F. J. Smith.

Annual Reports.—The annual report of Council for the year 1916-17, together with the financial statement for the year ending December 31st, 1916, was approved and adopted. The annual report of the Representatives on the

Council was submitted, and, in accordance with the rules of the Branch, received.

The late Dr. Major Greenwood.—The President reported the death of his predecessor, Dr. Major Greenwood, and a vote of condolence was passed.

Induction of President.—Dr. HAWTHORNE was then inducted to the chair, and delivered an address on the clinical organization of the profession.

METROPOLITAN COUNTIES BRANCH: CAMBERWELL DIVISION.
The annual general meeting of the Camberwell Division was held in the Board Room of the Guardians' Offices, Peckham, on June 21st, when Dr. H. G. CLITHEROW presided.

Annual Report.—The annual report and financial statement were received and adopted.

Election of Officers.—The following were elected for the ensuing year:

Chairman: Dr. H. G. Clitherow. *Vice-Chairman:* Dr. J. Heard.

Honorary Secretary and Treasurer: Dr. A. F. Heald.

Representative to Representative Meeting: Dr. F. C. Langford.

Representative of Branch Council: Dr. W. T. Partridge.

Executive Committee: Drs. G. B. Batten, A. D. Brenchley, H. G. Cowie, C. Cooper Cripps, C. H. Fring, W. G. Stone, R. Tilbury.

Fees for School Clinics.—A question having arisen as to the increasing disposition on the part of public bodies to reduce medical fees on every possible opportunity, the following resolution, proposed by Dr. C. COOPER CRIPPS and seconded by Dr. BATTEN, was carried:

That the Honorary Secretary be instructed to send a letter of protest to the British Medical Association against any reduction of fees for school clinics, the protest to be supported by documentary evidence.

Ministry of Health.—The Division meeting was followed by a meeting—of which the whole of the local profession had been notified—called to consider the circular (D 15) containing recommendations relative to the establishment of a Ministry of Health. It was decided that the recommendations be approved, and the following suggestions be submitted:

1. That under "Central Organization," Clauses 4 and 5, a condition should be that the medical members of the Board mentioned be elected by the medical profession of Great Britain.

2. That under "Local Organization" this extra clause be added: "That for each area there should be a local medical committee with administrative powers, such committee to be elected by the practitioners resident in the administrative area."

MIDLAND BRANCH: LEICESTER AND RUTLAND DIVISION.

THE following officers have been elected for 1917-18:

Chairman: Dr. Harris. *Vice-Chairman:* Captain W. M. Holmes. *Honorary Secretary and Representative to Representative Meeting:* Major R. Wallace Henry.

Representatives on Branch Council: Dr. Harris, Major Henry, Captain Waite, Dr. T. Bell.

Executive Committee: Dr. Binns, Captain Foster, Captain Stamford, Captain Young, Major Blakesley, Dr. Jenkins, Dr. Ballard.

NORTH WALES BRANCH: DENBIGH AND FLINT DIVISION.
The annual meeting of the Division was held at Chester on June 15th.

Election of Officers.—The following officers were elected for the ensuing year:

Chairman: Dr. E. D. Evans (Wrexham). *Vice-Chairman:* Dr. Henry Lloyd (St. Asaph).

Representative for Annual Representative Meeting: Dr. T. Roberts (Wrexham).

The representatives on the Branch Council, the Executive Committee, and the Secretary were re-elected.

Ministry of Health.—The meeting approved of the general principles laid down for the establishment of a Ministry of Health, and instructed the Representative accordingly.

Rhythmical Spasm of Pharyngeal Muscles.—Dr. DRINK-WATER (Wrexham) showed a case of rhythmical spasm of the pharyngeal muscles with typical tic.

Public Health Laboratory.—Dr. E. OWEN PRICE (Bangor) presented his scheme for the establishment at the University College of North Wales, Bangor, of a public health laboratory to serve North Wales—as published in the JOURNAL of April 28th, 1917, p. 562—and expressed his ambition for the establishment of a chair in bacteriology.

and the pursuit of research work on the level of that carried out at the older universities. The meeting considered that to serve the needs of the industrial area in the west of North Wales a laboratory was also needed at Wrexham, and that the more ambitious part of the scheme required a much larger capital than that at present proposed. It was decided to give hearty support to the scheme as outlined by Dr. Price.

SOUTH-EASTERN OF IRELAND BRANCH.

An ordinary meeting of the Branch was held in the Town Hall, Clonmel, on June 6th, when Dr. R. R. O'BRIEN was in the chair.

Supply of Pure Milk.—On the motion of Dr. LAFFAN, seconded by Dr. POWER, it was unanimously resolved:

That the resolutions relating to milk passed at the last meeting be sent to the Local Government Board with a request that they take immediate and practical action on the question. (See SUPPLEMENT, June 2nd, p. 124.)

The Annual Subscription to the Association.—The following notice of motion was deferred for the general consideration of the profession:

That the annual subscription be reduced to the original figure of one guinea, and that we urge same on the constituent bodies of the Association.

Reports of Meetings.—On the motion of Dr. LAFFAN, seconded by Dr. JELLET, it was unanimously resolved:

That the reports of Branch meetings in Ireland should be reported in greater detail and without unnecessary delay, and, further, that more prominence should be given to Irish medical affairs in the JOURNAL.

Association Notices.

ANNUAL REPRESENTATIVE MEETING, 1917.

Date of Meeting.

The Annual Representative Meeting of the Association will be held at the Connaught Rooms, Great Queen Street, London, W.C., on Thursday, July 26th, at 10 a.m. and following day(s) as may be required.

Agenda of A.R.M.: Further Notices of Motion by Divisions and Branches.

The provisional Agenda of the Annual Representative Meeting, including the Annual Report of the Council, was published in the SUPPLEMENT of May 5th, and a supplementary Notice of Motion in the SUPPLEMENT of June 2nd. The Supplementary Report of the Council was published in the SUPPLEMENT of July 7th. There will be included in the final Agenda of the Meeting, as to be issued to the members of the Representative Body on or about July 9th, not only the Notices of Motion published in the SUPPLEMENTS of May 5th, June 2nd, and (Supplementary Report of Council) July 7th, but also Notices of Motion received up to Thursday, July 12th, found by the Agenda Committee to be in order.

By order,

ALFRED COX,

Medical Secretary.

July 11th, 1917.

ANNUAL GENERAL MEETING.

NOTICE is hereby given by the Council that the Annual General Meeting of the British Medical Association will be held at the Connaught Rooms, Great Queen Street, London, W.C., on Friday, July 27th, 1917, at 2 o'clock in the afternoon. **Business:** (1) Minutes of last meeting. (2) Appointment of auditors (Messrs. Price, Waterhouse, and Co. offer themselves for re-election). (3) Award of Siddemore Prize. (4) Report election of President.

By Order,

GYV ELLISTON,

Financial Secretary and Business Manager.

Dated this 7th day of July, 1917.

429, Strand, London, W.C.2.

RANCH AND DIVISION MEETINGS TO BE HELD.

NORTH WALES BRANCH.—Dr. J. R. Prytherch, Honorary Secretary (Llangefni, Anglesey), gives notice that the annual meeting of the North Wales Branch will be held at the University College, Bangor, on Wednesday, July 18th, at 3.15 p.m. The Branch Council will meet at 2.45 p.m. The meeting is being held at Bangor in deference to the wishes of members who desire to attend the Graduation Ceremony in the morning. An associate member of the Branch, Sir Robert Jones, B., will receive an honorary degree of the university.

SOUTH MIDLAND BRANCH: BUCKINGHAMSHIRE DIVISION.—Dr. Arthur E. Larking (Secretary) gives notice that a meeting of the members of the Bucks Division, to which all medical men in the county are invited, will be held at the Crown Hotel, Aylesbury, on Thursday, July 19th, at 2.45 p.m., to re-elect the Local Medical War Committee, discuss the question of the formation of a Ministry of Health, consider matters relating to payments under the National Insurance Act, and other matters. Tea will be provided.

Meetings of Branches and Divisions.

DORSET AND WEST HANTS BRANCH.

THE summer meeting of the Branch was held at the Royal Naval Hospital, Portland (by kind permission of Fleet Surgeon J. Shand, R.N.), on July 11th, when the President, Dr. T. HOWARD, was in the chair. Prior to the meeting the members were entertained to luncheon by the President at his house.

Autumn Meeting.—It was decided to hold the autumn meeting at Bournemouth in October.

Scientific Proceedings.—Temporary Surgeon C. H. S. TAYLOR, R.N., read a paper entitled, "Some experiences with the Royal Naval Division in Antwerp, Gallipoli, and France," and made special reference to the treatment of sanitary questions at the front. Afterwards a demonstration was given at the hospital on the diagnosis and treatment of venereal diseases, and the technique of the intravenous administration of galyl was illustrated by the injection of a patient. Some x-ray photographs and clinical cases in the wards were shown and the members then adjourned to Dr. Shand's house where they were entertained to tea.

LEINSTER BRANCH.

THE annual meeting of the Leinster Branch was held in Dublin on June 19th, when Dr. R. L. HEARD was in the chair.

Election of Officers.—The annual report and financial statement were read and adopted, and the following officers were elected for 1917-18:

President: Surgeon A. Blayney. *President-elect:* Dr. H. Jellett. *Vice-Presidents:* Dr. W. V. Furlong, Colonel Johnston, R.A.M.C.

Honorary Secretary and Treasurer: Dr. W. Doolin.

Representative on Council of Association: Dr. W. Doolin.

Representatives of Branch on Irish Committee: Drs. James Craig, J. M. S. Kenny.

Ministry of Health.—A subcommittee, consisting of Drs. D. Jackson, Katharine Maguire, R. J. Rowlette, and Ella Webb, was appointed to report regarding the proposed legislation in connexion with the physical welfare of mothers and children, and the establishment of a Ministry of Health.

Remuneration for Doctors attending V.A.D. Hospitals.—The following motion proposed by Dr. Good, seconded by Dr. JACKSON, was passed unanimously:

That this meeting of the Leinster Branch strongly disapproves of the manner in which the War Office has concealed the fact that medical officers to V.A.D. hospitals are entitled to State remuneration for attendance at such hospitals.

SUSSEX BRANCH.

THE annual meeting of the Branch was held in the Town Hall, Hastings, on July 4th, when Dr. G. LOCKE was in the chair.

The members were entertained at lunch by Dr. Locke, who was supported by the Mayor of the borough.

Election of Officers.—The following officers were elected:

President: Dr. George Locke, J.P. *Vice-Presidents:* Dr. W. Muir Smith, J.P., Dr. H. C. L. Morris.

Honorary Secretary and Treasurer: Dr. A. M. Dady.

The financial statement was adopted and Chichester selected for the next annual meeting.

Presidential Address.—Dr. LOCKE delivered an address in which he referred to the proposed establishment of a Ministry of Health, and said it seemed impossible to prophesy as to the future of medical work because the country was on the edge of great changes—social, political, and financial—but the profession should consider what it could do to guide decisions. It must be careful with regard to the social changes likely to take place, otherwise there was the risk of medical practitioners becoming the servants instead of the advisers of the public. If doctors became State officials they would probably be drawn into the vortex of public affairs and unwillingly into strife. Strong organization was a necessity, and he considered that the British Medical Association was their best defence. He suggested that like trade, labour, and wealth, the British Medical Association should have a representative in Parliament. He supported the proposal for a Ministry of Health, and contended that the president should have Cabinet rank and be a medical man. He concluded his address by proposing a motion in favour of the establishment of a Ministry of Health on the lines recommended by the Central Council, which after some discussion was adopted.

Association Notices.

ANNUAL REPRESENTATIVE MEETING, 1917.

THE Annual Representative Meeting of the Association will be held at the Connaught Rooms, Great Queen Street, London, W.C., on Thursday, July 26th, at 10 a.m. and following day(s) as may be required.

By order,

ALFRED COX,

Medical Secretary.

July 11th, 1917.

ANNUAL GENERAL MEETING.

NOTICE is hereby given by the Council that the Annual General Meeting of the British Medical Association will be held at the Connaught Rooms, Great Queen Street, London, W.C., on Friday, July 27th, 1917, at 2 o'clock in the afternoon. *Business:* (1) Minutes of last meeting. (2) Appointment of auditors (Messrs. Price, Waterhouse, and Co. offer themselves for re-election). (3) Award of Middlemore Prize. (4) Report election of President.

By Order,

GUY ELLISTON,

Financial Secretary and Business Manager.

Dated this 7th day of July, 1917.

429, Strand, London, W.C.2.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are announced by the Admiralty:—Fleet Surgeons: P. T. Sutcliffe, M.B., to the *President*, additional, for service at the Medical Department; W. P. Dyer to the *Cornwall*. CURRENT NOTES.

White Bread for Invalids.

In consequence of various statements in the lay press to the effect that the Food Controller had decided to allow the purchase of "white" bread to those who find bread of the official standard indigestible or harmful to health, and who can furnish a medical certificate in corroboration of their view, a letter was addressed on behalf of the British Medical Association to the Food Controller on July 17th, asking for an exact statement by the Food Controller and information as to the way in which it was intended that the procedure should be carried out. In reply, the Association has been informed that invalid applications for superior flour should, in the first instance, be made by the invalid direct to the Ministry of Food, Grosvenor House, London, W.1, which will forward forms direct. The first form addressed to the applicant asks for a doctor's certificate and the name of a miller willing to manufacture a superior flour at the cost of the applicant. The medical certificate is in the following form:

Form II.

I hereby certify that I am in professional attendance on who is suffering from and that in my opinion it is essential that he (or she) should be supplied with superior flour to the regulation grade during the next weeks.

Signature

It is not the policy of this department to issue licences freely, otherwise it would be open to serious abuse; therefore please only sign above certificate in case of urgent necessity.

The Reorganization of Recruiting.

At a meeting of the Joint Committee of representatives of the Committee of Reference of the Royal Colleges of Physicians and Surgeons in England and of the Central Medical War Committee on July 17th it was resolved to summon a joint meeting of the full committees on July 25th to consider, among other matters, the propriety of submitting to the Government a scheme for the constitution of recruiting medical boards throughout the country. Meanwhile, on July 23rd, Lord Derby gave evidence before the Select Committee, as reported under Parliamentary Notes (p. 126), and stated that he desired that the whole of the recruiting should be taken out of the hands of the War Office and of the military authorities and entrusted to a civilian department. He made it a condition that "a civilian body should find the men, and until the men had gone through various processes to ascertain whether they could be spared from their civilian employment and whether they were fit for the various categories of service the army required, they should not come under the authority of the military." In view of this declaration, the joint meeting of the two committees on July 25th adopted unanimously the following resolution:

That this joint meeting of the Committee of Reference and the Central Medical War Committee communicate at once to the Prime Minister, the Secretary of State for War, the President of the Local Government Board, and the Chairman of the Select Committee (Mr. Shortt), its view:

1. That in any reorganization of the recruiting machinery of the country it is absolutely necessary that, as regards

the medical examination of men, the selection of the doctors to serve on the medical boards throughout the country should not be left wholly in any local hands, but should be supervised by a central body in order to obtain adequate uniformity of standard, and

2. That the selection should be made under the auspices of these two bodies (the Committee of Reference and the Central Medical War Committee) jointly, who are preparing a scheme for this purpose, which they will have the honour of submitting to the Government for its consideration.

PENSIONS AND GRANTS FOR DISABLED OFFICERS AND RELATIVES OF DECEASED OFFICERS.

THE promised draft of a Royal Warrant for the retired pay of officers disabled and for the pensions of the families and relatives of officers deceased, and for the pensions of nurses disabled in the present war, has been presented to Parliament.

Its general terms are explained in the body of the JOURNAL (p. 122), but we reproduce here the two schedules showing the rates of retired pay to disabled officers, and of pensions, gratuities, and allowances to officers' widows and children, together with some explanatory notes.

FIRST SCHEDULE.

Retired Pay to Disabled Officers.

		Retired Pay on Account of Disablement.						
		Officers not holding Permanent Commissions in Regular Forces.						Officers holding Permanent Commissions in Regular Forces.
Degree of Disablement.	Percentage Degree of Disablement.	Major-General.	Brigadier-General.	Colonel.	Lieutenant-Colonel.	Major.	Captain, Lieutenant, or Second Lieutenant.	All Ranks.
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
1	100	£ 350	£ s. 325 0	£ s. 275 0	£ 250	£ s. 225 0	£ s. 175 0	£ 100
2	80	280	280 0	220 0	200	180 0	140 0	80
3	70	245	227 10	192 10	175	157 10	122 10	70
4	60	210	195 0	165 0	150	135 0	105 0	60
5	50	175	162 10	137 10	125	112 10	87 10	50
6	40	140	130 0	110 0	100	90 0	70 0	40
7	30	105	97 10	82 10	75	67 10	52 10	30
8	20	70	65 0	55 0	50	45 0	35 0	20

Notes.

An officer who has lost the sight of both eyes as the result of wounds received in action shall be granted not less than £300 a year in wounds pension and retired pay taken together.

In the case of pecuniary need a disabled officer in receipt of retired pay may be granted an education allowance not exceeding £50 a year in respect of each child above the age of 9.

An officer who shows that the retired pay which he has been granted, together with any wound gratuity or pension of which

he is in receipt, together with the average earnings (if any) of which he remains capable, are less than his pre-war earnings, may be granted temporarily or permanently in lieu of such retired pay, retired pay which, together with the wound gratuity or pension and the average earnings (if any) of which he is judged capable, shall not exceed his pre-war earnings up to a maximum of £300 a year, plus half any pre-war earnings between £300 and £600 a year.

"Pre-war earnings" means the average earnings of an officer during the twelve months preceding the commencement of the war, or such lesser period as he was employed, and shall be computed generally in such manner as is best calculated to give the rate at which he was being remunerated, and so far as may be applicable, in the same manner as for the purposes of the Workmen's Compensation Act, 1906. In the case of a man in trade, business, or profession, the average profits of the last three years preceding the commencement of the war shall be taken, or of such lesser period as he engaged therein.

If an officer's disablement is not permanent the grant of retired pay and allowances will be temporary and will not be made permanent unless the permanency of the disablement is established.

If the degree of disablement is assessed at less than 20 per cent. or if the Minister of Pensions considers it more in the interests of the officer, a gratuity or temporary allowance may be granted in place of retired pay; the amount of the grant will depend on the nature of the disablement and other circumstances, and will not exceed £500.

An officer who retires, relinquishes his commission, or is placed in the Territorial Force or Reserve on account of medical unfitness neither attributable to nor aggravated by military service, and not due to serious negligence or misconduct of the officer, may be granted a gratuity or temporary allowance, the amount to be determined by the Minister of Pensions. In exceptional circumstances it may amount to a sum not exceeding £300, and generally will depend on the extent to which the officer is incapacitated and on the other circumstances of the case.

Grants or pensions may be made to the parents (including a grandparent who has been in the place of a parent to an officer and wholly or mainly supported by him) or to sisters or brothers wholly or partially dependent on him subject to the discretion of the Minister of Pensions.

SECOND SCHEDULE.

Pensions, Gratuities, and Allowances to Officers' Widows and Children.

Rank.	Widow's Pension.		Widow's Gratuity.	Children's Allowances.	
	Art. 11 (1).	Art. 11 (2).	Art. 11 (3).	Art. 12 (1).	Art. 12 (1).
(1)	(2)	(3)	(4)	(5)	(6)
Field Marshal ...	800	600	3,500	30	25
General ...	600	450	3,000	30	25
Lieut.-General ...	500	375	2,000	30	25
Major-General ...	400	300	1,100	30	25
Brigadier-General ...	300	225	900	30	25
*Colonel ...	200	150	600	24	20
†Lieut.-Colonel ...	180	135	450	24	20
Major ...	140	105	300	24	20
Captain ...	100	75	250	24	20
Lieutenant ...	100	75	140	24	20
Second Lieutenant	100	75	100	24	20

* Colonel means a Colonel who has been employed as a substantive Colonel if a combatant officer, or in the rank of Colonel if a medical, veterinary, or departmental officer.

† Including a Colonel not employed as above.

Notes.

Article 11 (1) applies "if the officer (a) is killed in action or suffers violent death due directly and wholly to war service . . . or dies within seven years from wounds or injuries so received; or (b) dies from illness which is certified as directly traceable to fatigue, privation, or exposure, incident to active operations in the field, within seven years after having been first removed from duty on account of such illness; or (c) dies in consequence of injuries received in the performance of military duty otherwise than under (a) within seven years after having been so injured."

Article 11 (2) applies "if the officer (a) dies of disease attributable to or aggravated by military service other than under Subsection (1) (b) within seven years after having been first removed from duty on account of such disease, or (b) dies of injuries attributable to military service other than under (1) (a), or (1) (c), and not through his own serious negligence or misconduct, within seven years after having been first removed from duty on account of such injuries."

Article 11 (3) provides for a gratuity in addition to a pension if the officer dies in the circumstances referred to in subsection (1) (a).

Article 12 (1). The widow of an officer awarded a pension under Article 11 (1) may be granted a further allowance as in column 5, and a widow awarded a pension under Article 11 (2) a further allowance as in column 6, for each child maintained by her. These allowances may be granted or continued up to the age of 18 in the case of sons and 21 in the case of daughters, unless the child is otherwise provided for or married, and may be granted or continued after the age of 18 in the case of a son who is an apprentice receiving not more than nominal wages, or is being educated at a secondary school, technical institute, or university.

A gratuity of one-third of the amount in column 4 may be granted in addition to children's allowance for each child if the officer dies in the circumstances referred to in Article 11 (1) (a).

The Minister of Pensions may grant to a widow who is in pecuniary need an education allowance not exceeding £35 a year for each child above the age of 9.

A pension to a widow will cease on her remarriage, but may be restored should she again become a widow.

The motherless child of an officer who has died in the circumstances set forth in Article 11 may be awarded a pension of £40 a year, but in the event of two or more children being maintained by one person the amount will be reduced to £35 for each of the children after the first.

Meetings of Branches and Divisions.

CAPE OF GOOD HOPE—EASTERN PROVINCE BRANCH.

A MEETING of the Branch was held at Grahamstown on June 8th, when Dr. J. A. LEA was in the chair.

Lady Health Visitor.—The meeting approved the employment of a lady health visitor on the terms suggested by a subcommittee of ladies connected with the Labour Bureau.

The late Dr. Herman F. Becker.—A vote of condolence was adopted to Mrs. Becker on the death of her husband, who for many years was a member and office-bearer of the Association, and whose loyal work for the town, science and art generally, was a lasting memorial to his memory.

Grahamstown Water Supply.—After a discussion on this subject, introduced by Dr. Lea, it was resolved to urge the Municipal Council to render impervious as soon as possible not less than 10 acres of the Slaai Kraal catchment as a measure for the necessary and immediate relief of the citizens.

Medical Insurance.—The Secretary reported the result of the canvass for medical insurance, and it was decided to inquire from the South Africa Committee whether dental surgeons insured under the scheme were eligible for benefits.

MUNSTER BRANCH.

The annual general meeting of the Branch was held at Cork on July 7th, when Dr. D. J. O'CONNOR, President, was in the chair.

Insurance.—The interim report of the Insurance Acts Committee was read and considered, but no action taken thereon.

Election of Officers.—The following officers were unanimously elected:

President: Dr. J. Dundon. *Vice-President:* Dr. M. A. Shinkwin. *Retiring President:* Dr. D. J. O'Connor. *Honorary Secretary and Treasurer:* Dr. Philip G. Lee. *Representative to Representative Meeting, 1917:* Dr. Philip G. Lee. *Deputy Representative:* Dr. D. J. O'Mahony. *Representative on the Irish Committee:* Professor H. Corby. *Council for 1917-18:* Drs. H. R. Townsend, Lucy Smith, O. McCarthy, D. J. O'Mahony, P. T. O'Sullivan, J. T. O'Connor, E. Murphy, Professor W. Ashley Cummins, R. R. Leader (Millstreet), R. Foott (Monkstown), J. Devane (Limerick), Humphrey O'Sullivan (Crookstown).

INSURANCE.

INSURANCE COMMITTEES.

COUNTY OF LONDON.

The Assignment of Insured Persons.—At the meeting of the London Insurance Committee on June 28th the scheme for the assignment of insured persons to practitioners, which has been in operation since 1914, was modified to meet the case of an insured person who had been refused acceptance by a doctor. It was agreed that a practitioner on refusing to accept an insured person who applied for acceptance or for treatment should inform the applicant that it was open to him to apply to another practitioner for acceptance, and should hand him a special form in order that he might apply to the Panel Committee. The practitioner who made the refusal should

also give such treatment as might be required pending assignment.

Panel Practice and War Emergency.—In view of the burden thrown upon panel practitioners remaining in civil practice owing to the number of their colleagues absent on war service, the Committee agreed to issue a notice asking insured persons not to make unnecessary demands on the time and services of doctors, and to present prescriptions to chemists without delay. Each practitioner is to be asked to exhibit this notice in his surgery, and a statement to the same effect is being published in the press.

LOCAL MEDICAL AND PANEL COMMITTEES.

COUNTY WICKLOW.

At a recent meeting of County Wicklow Local Medical Committee the following resolutions were unanimously passed:

1. That the Committee believes that the numbers of insured persons returned by the National Health Insurance Commission as resident in certain areas in County Wicklow are very much underestimated, and that our secretary be instructed to ascertain from the Commission how the numbers of insured persons as given by them have been calculated.
2. The Committee is anxious to know if certificates issued to insured persons resident in, but not insured in, a particular dispensary area, are paid for; and, if so, on what basis?
3. That the Committee, representing the medical practitioners of the county, demands an increase of remuneration for medical certification out of the £25,000 per annum which has been unexpended by the National Health Insurance Commission for medical referees.

CHESHIRE.

At a meeting of the County Palatine of Chester Local Medical and Panel Committee on March 25th the following resolution was carried unanimously:

That in any scheme for the development of the medical service of the public the free right of the patient to select the doctor who is actually to attend him in illness should be preserved, and the right of the doctor to accept or refuse a patient should be recognized.

At an adjourned meeting of the Local Medical and Panel Committee on April 1st it was decided to inform the county medical officer of health that the employment of midwives for medical work does not constitute a satisfactory scheme, but that in cases where practitioners choose to undertake the examination of specimens of urine a suitable fee for examination and report on each specimen would be 5s. It was decided that the fees for the remuneration of practitioners called in by a midwife should be:

For all difficult cases (this to cover attendance for fourteen days)	£	s.	d.
And that the fee for subsequent attendance should be	0	3	6

And that otherwise the British Medical Association scale, including the fee for anaesthetic of £1 ls., be approved.

BIRMINGHAM.

At a meeting of the Panel Committee on June 5th it was decided to again approach the Commissioners with regard to the appointment of a medical man on the Insurance Committee. It was decided to ask the Insurance Acts Committee of the British Medical Association to bring the following resolution before the Commissioners:

That the medical card, being the only evidence of title to medical benefit, should bear the date of issue, and that the period allowed to elapse between issue and presentation to doctor for signature should be limited.

It was decided that the present Committee should continue in office till July 15th, 1918. The Secretary was instructed to inform the Birmingham Citizens' Committee that panel doctors would be recommended on the termination of each case to fill in the necessary particulars as to treatment of discharged soldiers and sailors for future reference.

COUNTY OF LONDON.

At the meeting of the London Panel Committee on June 26th a recommendation was brought forward that a conference of delegates from all the Panel and Local Medical Committees in the country should be summoned by the

London Committee to discuss the general question of closer co-operation and co-ordination. This was amended to include only those committees which had replied in sympathetic terms to the recent referendum of the London Committee. It was stated that favourable answers had been received from the great majority of committees, including the most important. Some members thought it unwise to start with a partial conference, but the amendment was carried and a special section of the Committee was instructed to make arrangements.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following notifications are announced by the Admiralty:—Fleet Surgeon J. E. Coad is placed on the retired list with the rank of Deputy Surgeon-General. Temporary Surgeons: L. B. Stringer to the *Europa*; A. H. Wear, M.B., to the *Daedalus* for Cranwell; A. C. McAlister, M.B., to the *Temeraire*; H. K. Shaw, M.B., to the *President*, additional, for Roehampton Hospital; H. W. Eddison, P. G. S. Davis, J. M. S. Nichol, M.B., and J. F. Howell to the *Pembroke*, additional, for Chatham Hospital; A. Strachan, M.B., to Chatham Hospital; K. McFadyen to Haslar Hospital; W. T. Beswick and L. B. Bartley to the *Fivid*, additional, for Plymouth Hospital; A. Pearce, S. S. Barton, D. W. MacKay, M.B., and W. T. Cooper to the *Victory*, additional, for Haslar Hospital; A. K. Roche, M.B., to the *Lord Nelson*; R. H. H. Newton to the *Truro* Auxiliary Naval Hospital, vice Roche; J. S. Farries to the *Pembroke*. To be temporary Surgeons: B. Thomas, J. F. Ryan, H. N. Dale-Richards, H. Rowan, W. E. Powell, W. D. Brunton, M.B.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon R. Wilbond promoted to Staff Surgeon; Surgeon Probationer P. Wilson to the *Victory*, for Haslar Hospital. To be Surgeon Probationers: W. Woodman, H. A. Potter, J. D. Whiteford, J. Macdonald.

ARMY MEDICAL SERVICE.

Colonel A. A. Sutton, C.B., D.S.O., to be temporary Surgeon-General.

ROYAL ARMY MEDICAL CORPS.

Majors R. H. L. Corder and A. A. Meaden relinquish the acting rank of Lieut.-Colonel on reposting. Major H. C. Sidgwick, M.B., retains the acting rank of Lieut.-Colonel whilst commanding a general hospital.

Temporary Major H. J. Shirley, M.D., F.R.C.S., to be temporary Lieut.-Colonel.

To be acting Lieut.-Colonels: Major G. E. Cathcart and Captain C. Clarke, M.B., F.R.C.S., whilst in command of a field ambulance; Major E. B. Booth, D.S.O., M.D., and Captain J. L. Wood whilst in command of a stationary hospital; Major A. B. Hinde (Reserve of Officers) whilst commanding a general hospital; Major H. R. Bateman, D.S.O., whilst commanding Officers' Convalescent Home, Michelham.

Major E. V. Aylen, D.S.O., to be temporary Lieut.-Colonel whilst commanding a R.A.M.C. Training Centre.

Temporary Captains to be temporary Majors: W. de M. Hill, H. Dickie, M.D.

W. C. McN. Dickey (late temporary Captain) to be Honorary Captain.

Temporary Captains relinquish their commissions: G. W. Whitman, M.D., C. O. Walsh, M.D., G. M. Shaw, M.B., H. M. Godfrey, M.D., A. D. Sharp, M.D., G. B. Burwell, M.C., M.B., J. H. Box, M.B., J. F. Ryan, M.B., W. J. B. Brown, M.B., H. G. Murray, M.B., G. A. Greaves, M.D., R. E. Johnston, M.B., D. A. Fletcher, M.B., H. Grey, M.D., A. G. C. Irvine (on account of ill health).

To be temporary Captains: J. Allan, J. Henderson, M.B., C. J. Heaton, A. E. Boycott, M.D., F.R.S., A. E. Moore, M.D.

Temporary Lieutenants to be temporary Captains: H. M. Gillespie, M.B., A. E. Francis, H. R. Hurter, M.D., J. MacInnes, M.B., S. R. Hunter, M.D., A. E. Wynne, M.D., F.R.C.S.I., J. L. Smith, M.B., R. J. Morgan, A. Gaston, D. C. Crole, M.B., G. de H. Dawson, J. Whiteside, M.B., J. W. Watthews, M.B., A. J. Hawes, M.B., B. Robertson, M.B., A. Smith, W. Sowerby, M.D., R. M. Morison, M.B., J. R. M. MacKenzie, M.B., J. McD. Matheson, M.B., A. H. B. Pearce, A. Wright, M.B., E. W. Toulmin, W. B. Hendry, S. H. Scott, J. McPolin, M.B., D. Walker, M.B., J. Byrne, V. E. Sorapure, M.B., F.R.C.S.E., R. M. McMinn, M.B., H. W. Hues, H. H. Tipping, H. M. Sturrock, C. S. Glegg, M.B., R. L. S. Nuthall, D. Campbell, T. B. A. Haggard, A. Morrison, A. W. Adams, W. L. Thomas, M. Graves, F. E. Dowling, J. F. Finlay, M.B., A. F. Fraser, M.B., L. Bensted, F. C. Morgan, J. F. C. O'Donohoe, M.B., H. E. T. Dawes, M.B., S. G. Graham, A. J. Ireland, M.D., W. S. Foote, R. J. Snider, M.B., G. W. Armstrong, W. B. Rutherford, M.B., G. Scullard, M.B., P. W. M. Curry, M.B., M. J. Loughrey, J. H. Fryer, M.B., P. A. Dykes, J. Graham, M.D., H. Whitwell, D. McCormack, C. J. B. Pasley, D. P. Blair, M.B., A. R. M. Brean, M.D., J. Clark, M.B., D. Collingham, F. D. Sauer, M.B., F.R.C.S., W. St. A. Hubbard, J. P. Mathie, J. A. B. Hammond, M.B., D. D. Pincock, M.B., F.R.C.S., T. S. Law, M.B., J. B. Donaldson, G. D. Watkins, J. D. Doherty, M.D., J. M. Lazenby, M.B., R. R. Law, M.D., C. W. Brown, M.B., A. E. B. Sim, M.B., R. C. Alexander, M.B., F.R.C.S.E., A. G. McKenna, C. B. Goulden, M.D., F.R.C.S., W. S. I. Robertson, M.B., S. A. Bull, M.D., F. W. Falconer, M.B., R. Roberts, R. E. Sedgwick, R. McL. Wishart, J. Monroe, M.B., A. E. Rayner, M.D., H. F. Bodvel-Roberts, S. J. W. Donald, M.B., J. S. Rowlands, M.D., D. Ranken, F.R.C.S., W. Fraser, M.B., W. K. Connell, M.B., W. D. Allan, M.B.

To be temporary Lieutenants: L. S. Davison, M.D., A. Fleming, M.B., F.R.C.S., A. G. McIntyre, M.D., W. B. Primrose, M.B., B. S. Johnson, W. T. McCutcheon, M.B., E. MacMahon, J. B. Cook, M.B., J. Grogono, E. W. Grogono, E. P. Harding, P. W. L. Camps, M.B., F.R.C.S., B. Kelly, T. A. Davidson, C. A. B. Horsford, M.D., F.R.C.S., E. W. Hiltne, M.B., T. Marron, M.B., W. E. Burrows, M.D., S. E. Holder, C. A. Lawrence, J. B. Baister, M.D., F.R.C.S.E., J. Ellenbogen, E. Morison, M.B., P. J. Hay, M.D., J. A. W. Ponton, M.D., J. C. Ryan, B. Suggitt, M.B., F. H. Diggle, M.B., F.R.C.S., A. M.

Macleod, M.D., A. Tait, M.B., M. S. Wood, M.D., A. R. Taylor, G. H. Hackney, O. Smith, M.B., J. Cross, M.B., R. C. Corbett, M.B., T. F. Murphy, C. H. G. Lyall, E. Morgan, C. Bernard, T. A. Davies, M.D., F. P. Nunneley, M.D., M. Dockrell, T. Kennedy, M.B., M. B. Phillips, M.B., C. B. Gerrard, M.B., C. B. M. Aldridge, R. N. Woodsend, M.B., J. McGibbon, M.B., R. T. A. Patchett, L. Wayne-Morgan, A. H. Gray, M.D., F. Crooks, M.B., A. MacMillan, H. Baird, M.D., V. J. Rigg, M. Aikman, M.B., P. L. Pollard, M.B., H. W. J. Hawthorn, W. Cook, M.B., R. S. Strachan, M.B., D. O. Fairweather, M.B., T. Fraser, M.B., C. Brash, M.B., R. Taylor, M.B., J. D. Oliver, M.B., F.R.C.S., J. A. Powell, M.D., J. N. M. Sutherland, M.B., A. Matheson, M.B., F. L. Thomas, M.B., J. W. A. Wilson, M.D., D. L. G. Radford, F. A. Morrison, M.B., D. P. Smith, M.B., P. A. Hendler, S. W. Swindells, M.B., A. Westernman, M.D., G. Eager, A. C. Farlinger, M.D., G. W. Bissett, M.D., H. F. Smith, M.D., E. G. D. Benson, G. Milne, M.D., J. W. Senter, M.B., C. M. Stevenson, M.D., U. Marks, T. B. Vaile, A. H. Duckett, M.B., J. J. Todd, D. W. Tacey, C. R. A. Thacker, M.B., W. Tudhope, M.B., H. R. Cran, R. N. Dunlop, M.D., J. G. Woolham, M.B., N. H. M. Burke, J. D. Hartley, F.R.C.S., J. D. Jones, P. Steele, M.D., G. Denbigh, M.D., A. F. Waterhouse, M. D. MacKenzie, M.B., L. D. Callender, M.B., J. Dawson, H. C. Taylor, J. B. H. Holroyd, H. E. Middlebrooke, W. H. Parkinson, M.B., H. W. B. Ruxton, M.B., H. Maffin, M.B., T. Brodie, M.B., J. G. Langley, M.D., F. de R. Martyn, W. B. Peacock, R. R. H. Wonnacott, A. O. Bisson, J. F. Lindsay, M.B., F. McG. Loughnaue, F.R.C.S., C. Gray, A. Rogers, G. D. Dawson, M.D., H. A. Mason, J. Gilchrist, W. E. Procurier, M.B., H. H. Stiff, M.B., J. Orr, M.B., J. W. McDougall, M.B., G. Nowat, M.B., D. R. C. Shepherd, M.B., C. L. Stewart, E. C. Roberts, M.B., H. F. Marshall, F.R.C.S.E., H. B. L. Allott, F. F. C. Willington, M.D., J. Good, R. C. Pitt, C. Visger, A. J. Adkins, W. H. Gibson, M.B., J. T. R. MacGill, M.B., D. Longwill, M.B., M. J. Macaulay, M.B., G. Ligertwood, M.B., F. H. Mosse, D. P. McDonald, M.B., L. D. Wright, R. Fraser, M.B., E. J. Manning, C. J. Taylor, F.R.C.S.E., W. Duguid, M.B., St. G. M. L. Homan, M.B., C. W. C. Harvey, G. E. A. Mitchell, M.D., T. R. Coudrey, P. J. O'Brien, M.B., J. Fortune, M.D., J. F. MacLeod, M.B., A. F. Horn, M.B., I. B. Richardson, W. Deane, C. H. Gunson, M.B., W. B. A. Moore, S. G. Johnson, R. W. Dale, M.B., J. Maxwell, M.D., A. G. Brand, M.B., A. S. Findlay, M.B., J. A. Hagerty, M.B., H. P. Wright, M.B., F. D. Scott, M.B., W. H. Gowan, M.B., A. G. Stewart, M.D., J. W. Robertson, M.B., F.R.C.S.E., A. G. J. Thompson, M.B., G. Garland, M. P. Thomas, A. R. Jennings, H. Thorp, M.B.

Temporary Lieutenants relinquish their commissions: R. B. Robson, M.B., R. F. Williams, M.C., M.B., J. Barrett, H. W. Gush, M.B., R. J. Wilson, M.B., A. McD. Nevin, M.B., J. A. Williams, M.D., L. E. Price, A. Dangerfield, M.B., F.R.C.S., J. R. Heath, H. P. Motteram, M.D., J. H. Watson, M.B., F.R.C.S., B. J. Courtney, M.D., H. E. White, M.B., S. Vardon-Roe, M.B., I. W. Dickson, M.B., F. Kinnear, M.B., K. S. Macky, M.B., E. F. Hoare, M.D., G. A. Campbell, H. D. Gasteen, A. K. Henry, M.B., F.R.C.S.I., V. A. Crinks, S. B. Turner, A. E. Hunter, M.D., D. P. Lacey, M.B., R. E. Marwick, M.B., A. P. F. Gammack, M.B., G. P. G. Beckett, M.D., C. L. Hawkins, M.B., W. D. Hopkins, G. W. Renton, M.D., A. J. Stanley, M.B.

Temporary honorary Lieutenants to be temporary honorary Captains whilst employed at the British Red Cross Hospital, Netley: E. W. Twining, L. W. Sharp.

Granted temporary honorary rank: As Captain, J. R. Taylor. As Lieutenant, H. D. Havard.

EIGHTY-FIFTH ANNUAL MEETING

OF THE

British Medical Association.

LONDON, 1917.

ANNUAL REPRESENTATIVE MEETING.

MR. E. B. TURNER, F.R.C.S. (Chairman of Representative Meetings), in the Chair.

The proceedings of the Annual Representative Meeting began on Thursday, July 26th, 1917, at the Connaught Rooms, London, at 10 a.m. The number of Representatives present was 137, and in addition 17 members of Council attended. The return of Representatives of Constituencies for 1917-18 was received, and the notices of appointment of substitutes were also received and entered on the minutes. The Standing Orders of the last Representative Meeting, subject to certain formal amendments, were approved, and the report of the Agenda Committee dealing with the order of business, was adopted.

On the motion of Dr. J. A. MACDONALD (Chairman of Council), the Annual and Supplementary Reports of Council were received.

Sir Thomas Clifford Allbutt, K.C.B., LL.D., was re-elected President of the Association for 1917-18 by acclamation. Dr. MACDONALD said that the preliminary part of the Report of Council recorded the deaths of those members of the Association who had lost their lives in the war. Nothing that he could say could add to the glory of these men; he could only express his poignant regret that the necessities of the country had called on so many of them to surrender their lives. Another list recorded the deaths of members other than those on active service; the list, unfortunately, was very long, and included many distinguished names.

This portion of the report was approved by the Representatives rising in their places.

THE MESOPOTAMIA COMMISSION.

Mr. N. BISHOP HARMAN (Marylebone) moved:

That this meeting desires to express to Lieut.-Colonel R. M. Carter its hearty congratulations on his public spirited and courageous action in persisting in bringing to the notice of the authorities the defects in the medical provision for the Mesopotamia Expedition; and places on record its pride in the knowledge that the credit of this action belongs to a member of the medical profession.

He said that the picture afforded by the report of the Parliamentary Commission on the operations in Mesopotamia, especially of the horrors of the medical break-

down, was very black; it was relieved by gleams of brightness, one of them being the reference to the gallantry of the troops, and another was that the work of the executive medical officers was praised in unmistakable terms. Lieut.-Colonel Carter, I.M.S., taking full count of what might be the consequences of his action, but venturing the whole of his future in order to bring to the notice of the authorities the defects of the medical provision, deserved to be commended and congratulated, because he retained under adverse conditions that independence of mind and soberness of judgement which was the first necessity in the making of a real doctor.

Dr. R. C. BUIST (Dundee) thought that the motion detracted from its compliment to Lieut.-Colonel Carter for performing his duty under difficult circumstances by its final clause, and Mr. HARMAN agreed to withdraw all the words after "Mesopotamia Expedition."

Dr. E. O. PRICE (North Wales Branch) had a motion to a similar effect, which he said he would be content to withdraw in favour of Marylebone, except for the last three lines of his own motion, which read: "And invites the Council to bestow upon Lieut.-Colonel Carter some mark of the Association's appreciation of the great services which he has thereby rendered to the army and to the State."

Dr. W. M. CROFTON (Leinster) said that Lieut.-Colonel Carter deserved all the encomiums that had been passed upon him, but he had been singularly fortunate. Other men had seen elsewhere the results of inadequacy and ineptitude, and had protested, but had been unable to make their protests effective. The temporary medical officers were seething with discontent. Efficiency received no recognition.

The motion as amended was carried, together with the rider proposed by Dr. PRICE, *nemine contradicente*.

THE FINANCIAL STATEMENT.

The Treasurer, Dr. G. E. HASLIP, moved the financial part of the Report of the Council (SUPPLEMENT, May 5th, p. 74). He thanked the meeting for the honour they did him last year in electing him to an office whose responsibilities were certainly aggravated by the times. Notwithstanding the war, however, the deficit of £55,000 outstanding at the end of 1913 had been reduced to £11,600 at the end of 1916. The Treasurer went over in detail the various items set forth in the report. With regard to the JOURNAL, he said that in round figures the total cost of production in 1913 was £40,000, and in 1916 £26,500. The total number of JOURNALS printed in 1913 was a million and a half copies, and in 1916 a million and a quarter copies; the decrease was due partly to a diminution in membership, and partly to reduction in the numbers of free and exchange copies. A great factor in influencing the finances of the Association had been the foresight

displayed by his predecessor, by the Chairman of the Journal Committee, by the Editor, and by the Financial Secretary in grasping the fact that the size of the JOURNAL must be diminished. The finances of the Association would be very different to-day had not that early economy been exercised. In 1913 the pages of the JOURNAL averaged 164 weekly; in 1916, 86. Its weight in 1913 was 14 oz., and the paper cost 1½d. a copy; in 1916 it weighed 6 oz., and the cost of the paper was 2d. a copy. He specially mentioned the cost of paper because this was advancing, from 2d. a lb. in 1913 to 5d. in 1915, and 7½d. to-day, and he was afraid the price would yet be higher. A further reduction in the size of the JOURNAL had been carefully considered, but up to the present this had not taken place; by keeping it at 84 pages in all, £45 a week was saved in postage. Looking at the position as a whole, he thought that the meeting would recognize that it had been possible substantially to consolidate the finances of the Association during the last three years, and it was the first time since the rebuilding of the Association's premises that there was nothing owing to the bank.

Dr. EDWIN RAYNER congratulated his successor on the very great ability he had shown during his year of office.

Expenditure of War Committees.

Dr. J. J. TISDALL (Liverpool) moved:

That a paragraph be added stating the total amount expended by the Central and Local War Committees, and what attempt has been made to recover this from the Government.

His Division was unanimous in believing that the Central and Local War Committees were the best possible machinery that could have been devised, and the manner in which they had worked was beyond all praise. Had it not been that a small minority of the local War Committees had misinterpreted the trust placed in them by the Council of the Association, this matter would never have been raised. As it was, a number of men had suddenly made the discovery, as they believed, that the Association had been using its funds illegally for this purpose, and with the enthusiasm of all discoverers had pressed the matter forward.

The TREASURER said that the cost of the Central Medical War Committee from its commencement in February, 1915, to September 30th, 1916, was £2,500, and from the latter date to July 25th, 1917, it was £3,980, making a total of £6,480. It was shown in the balance sheet (SUPPLEMENT, May 7th, p. 77) as £2,704 for the whole of 1916. The cost amounted to about 2s. 7d. a member of the Association for 1916. That included the expenses of all local War Committees that had made returns.

Dr. TISDALL, in view of the Treasurer's explanation, withdrew his amendment, and also another which stood in the name of his constituency requiring that the proportional amount of each member's subscription involved in the War Committee's expenses be inserted in the financial statement.

Payment of Subscriptions.

Dr. NOY SCOTT (Plymouth) pointed out that the arrears of subscriptions amounted to something like £3,000, and in an Association composed of men who could certainly afford to pay their subscription within the proper time this should not be allowed. He therefore moved:

That the Council be instructed to consider an alteration of by-laws to provide that no one be recognized as a member of the Association whose subscription is not paid on or before September of each year.

Dr. H. MARSHALL (Gloucestershire) formally seconded.

Dr. MACDONALD said that it would not be advisable for the Council to enter any such restriction on the by-laws. The loss from subscriptions in arrear was only something like 2 per cent. The Council was prepared to consider the matter again, but it had already been considered several times. The TREASURER said that the arrears written off were £1,578, not £3,000, as stated by Dr. Scott. The other, it was hoped, was good money.

The amendment was lost, and the financial report was then finally approved.

THE ASSOCIATION AND THE WAR.

Dr. T. JENNER VERRALL, Chairman of the Central Medical War Committee, moved the approval of the

Report of the Council with reference to that Committee. He said that he was under no delusion as to the serious nature of the matters to be considered, and no one would object to criticism. As the war proceeded the supply of medical men for the army must be more and more difficult, and there must come a point when there would be no further supply. The action of the War Office in April in calling up every medical man under 41 took the Committee by surprise. This action, without notification to and consultation with the Committee, was not in accordance with what was understood to be the proper order of things. The result for the time being was disastrous, for it brought about a condition of things under which the Committee could not work. Lord Derby, with his usual courage and promptness, accepted the Committee's protest in the spirit in which it was made. His letter was a prompt reversal of the decision, so far as that could be reversed, which had already caused considerable mischief. It was a matter for congratulation that this protest, followed by Lord Derby's recall of his action, had not, he was glad to say, resulted in any bitterness between the Army Medical Department and the Committee; its relations with Sir Alfred Keogh were as cordial now as before. With regard to the question of mobilizing the medical profession, he could not go specifically into the recommendations which were now under the consideration of the Director-General of National Service, but the resolutions given in the SUPPLEMENT (May 7th, p. 82) were in general taken as a basis for the consideration of the conference. The utilization of men found unfit for general service was another matter which the Committee had to face, owing to the fact that it was constantly being forced upon it during the hearing of appeals. Obviously a man might be quite fit to work in civil life, but unfit to take his part in a campaign, but it was some satisfaction to find that on the representations of the Committee the basis of classification was altered so that commissions could be given to men whose physical standard made them available only for home service, which included the base hospitals in France, where the conditions of service were no more arduous than those prevailing in this country. On the question of protecting the practices of the men on active service, he noted that the President of the General Medical Council had taken upon himself in one of his addresses to say that, without going into chapter and verse, the Council so far as it had the power would be prepared to exercise it in the direction of discountenancing as disgraceful any local disloyalty to absent men. Finally, Dr. Verrall referred to the report prepared by joint representatives of the War Committee and the Committee of Reference on the subject of the treatment of the dischargeable disabled soldier, and said that he had reason to hope that the plan put forward, although not at once accepted in its entirety, might yet help the Government in evolving a workable and efficient scheme.

Disbursement of Association's Funds.

The CHAIRMAN, referring to an amendment by Liverpool with regard to the disbursement of the Association's funds on the expenses of the Central and Local Medical War Committees, said that this matter came up at the last Representative Meeting, and on taking legal opinion it was decided that the question of spending money on these committees was one which came well under the memorandum of the Association. The Solicitor was prepared again to give the same opinion as he gave on the last occasion.

Dr. TISDALL, who was in charge of the Liverpool amendment, said that this was not an attack on the War Committees. Any controversy must revolve around the point as to whether paragraph 3 of the Memorandum of Association could be stretched to bring in this expenditure. Liverpool felt that if this went without a protest some future Council might call upon them to spend money on other and less laudable objects. They were fearful that this might become a precedent.

Dr. MACDONALD said that the Solicitor was prepared to stand by the advice he gave last year. The Association was empowered to spend money for the honour and interests of the profession; was it not for the honour and interests of the profession that the Committee had acted as it had in the case of the War Office call last April?

The amendment was lost by a large majority.

Personnel of Central Medical War Committee.

Dr. TISDALL (Liverpool) then moved:

That the list of names (of the Central Medical War Committee) should specify which are members of the British Medical Association and which are not, and in the case of the latter what they represent.

Dr. VERRALL described the help which the four members of the Committee who were not members of the Association had been in the work of the Committee. One of them, Dr. A. E. Shipley, was not even a medical man, but he was Master of Christ's College, Cambridge, and rubbed shoulders with so many medical men, present and prospective, that he might almost be regarded as semi-qualified. (Laughter.) He had rendered most valuable assistance.

Dr. D. A. SHEAHAN (Portsmouth) asked whether it was legal for a committee to spend the funds of the Association when some of its members were not members of the Association, and was informed that it was. The amendment was withdrawn.

Railway Fares.

A further amendment by Liverpool urged that the appropriate paragraph in the report (para. 23, p. 81) should show whether the Association paid the difference between first and third-class fares of members of the committee and witnesses. The TREASURER said that the Association made up the difference so far as members of the committee and witnesses summoned to assist the committee, and the amendment was withdrawn in view of the Treasurer's explanation, as was a further one by Liverpool disapproving of paragraph 24.

MOBILIZATION OF THE MEDICAL PROFESSION.

Dr. TISDALL further moved on behalf of Liverpool:

That the Representative Body strongly disapproves of any attempt being made to control the liberties of members of the medical profession differently from those of other members of the community.

Liverpool wanted to know why medical men should be singled out as the only body of men in the country to be coerced.

Dr. VERRALL said that the principle that it was unwise and unfair to limit the liberties of a portion of the community and not the liberties of the community generally might in a general way be accepted; but the reason why it might be necessary for the Government to adopt some plan whereby the medical men remaining in the country should contribute to the greatest possible extent in attendance on the civil community by shifting such men from parts of the country where they might be superfluous to parts where they were sorely needed, was simply the hard and terrible necessities of the country, in the face of which many principles which ought to be supported in peace time had to go by the board. It was the same principle as that of restraining the sale of sugar while not touching certain other commodities.

The amendment was lost, as was a further amendment by Dr. TISDALL, with which he said he did not associate himself, to the effect that it should not be described as a matter of regret but as a matter of congratulation that, as stated in the report, the proposed joint interview with the Director of National Service never took place; and on yet another Liverpool amendment,

That it is not the duty of the Association to use its machinery to increase the powers of the General Medical Council or to endeavour to get practitioners struck off the Register for disobeying rules formed by committees which are not committees of the British Medical Association,

Dr. BUIST (Dundee) moved that the meeting proceed to the next business, which was carried.

Captain FOTHERGILL (Brighton) moved:

That this Representative Meeting approves the resolution of the Central Medical War Committee passed in December, 1916, re mobilization of the medical profession, provided such mobilization be carried out on a scheme approved by the profession under the direction of its accredited representatives.

The general practitioner who had not joined the army saw that he might be transferred by a body or an individual who knew nothing whatever of the interests of public health. The words at the end of the rider simplified the position; the practitioner was willing to go here or there

provided that his own professional colleagues determined that it was necessary.

Dr. VERRALL said that he thought the resolutions of the committee given in the report met Captain Fothergill's case, for the suggestions and proposals would be carried out under the direction of accredited representatives of the profession.

Dr. F. L. POCHIN (Oldham) asked who were the accredited representatives of the profession on this matter.

Captain FOTHERGILL said that the War Committee was in the minds of those who framed the rider. He added, in reply to Major D. F. TODD (Sunderland), that he was quite willing to insert the words, "War Committee."

Dr. VERRALL pointed out that the Central Medical War Committee only dealt with England and Wales, the Committee of Reference only with the metropolis. He suggested that the words, "on a scheme approved by the profession," be left out altogether.

Dr. C. E. ROBERTSON (Glasgow) said that a meeting of practitioners in the Glasgow district was absolutely unanimous in declaring that they would not permit themselves to be mobilized until the workers of every other body were mobilized at the same time.

Dr. J. STEVENS (Edinburgh and Leith) said that in his Division a similar resolution was passed, and one such resolution at least was passed in London. There was no doubt that there was a considerable opinion throughout the profession that it would not be a wise or a good thing that it should be mobilized in advance of other sections of the community. His conviction was that the profession could do a larger and better service, not only for the war but for the civil population, if it were not mobilized and made to serve under some cut-and-dried scheme.

Dr. BUIST (Dundee) hoped that it would not be assumed that Scotland was unanimous in support of the opinions just expressed.

Captain FOTHERGILL's amendment was carried after the substitution of the words "under the direction of accredited representatives of the profession" for all the words after "carried out."

Dr. J. V. C. DENNING (Lambeth) said that he had no criticisms to make of the general work of the War Committee, and he was sure the interests of practitioners were in the best hands. But he had one or two things in the nature of suggestion to offer. The first was the question of rank. It was perfectly well known that the callowest curate in England, when he entered military service, became a captain; a medical man was a lieutenant. There were a good many men between 35 and 40 with a vast amount of experience who felt this very strongly. Then there was a feeling among a very large number of elderly men (elderly, he meant, in the military sense) that very often they were sent to the front, whereas young men were sent to camps in England. His last point was that the present difficulties in conducting practices at home would be relieved if a number of superfluous men now in France were brought back to home practice. Abroad there seemed to be little beyond the two alternatives, once suggested as true of the future life—an eternity of misery or an eternity of ennui. The misery was in the trenches, and the ennui almost anywhere else.

Dr. J. HUNTER (The Lothians), referring to the paragraph in the report with regard to the cancelling of the veto on the resignation of officers in the R.A.M.C., said he knew personally of one instance where an officer who had served his two years in May came home from France, having sent in his resignation, and was immediately sent back to France by the War Office, and not allowed to resign.

Dr. VERRALL, in reply to Dr. DENNING, referred to paragraph 27 of the report, from which it would be seen that representations had been made to the Director-General from time to time in favour of the substitution, where possible, of older men for the younger men employed at home and eligible for service abroad. The question of rank and many similar questions were not neglected, but were taken up on occasion with the Director-General, and had been received courteously, even if the Committee had not always got all that was desired. With regard to doctors being sent back to France after having served their two years, one thing must not be forgotten: a man who returned, whether he had served one, two, or three years, if under 41, was liable to military service, and therefore, unless he received exemption on appeal, he was liable to go

back. Certainly an opportunity should be afforded to lodge an appeal, in which case it would be heard by the Central Medical War Committee, the Committee of Reference, or the Scottish War Emergency Committee, which held a statutory position for this purpose.

SUPPLEMENTARY REPORT OF COUNCIL: CENTRAL MEDICAL WAR COMMITTEE.

Payment of Medical Officers of V.A.D. Hospitals.

The first part of the report having been approved, Dr. VERRALL moved the approval of the Supplementary Report (SUPPLEMENT, July 7th, page 2) relating to the work of the Committee. He said that originally it was well known that *à la suite* territorial officers would in time of war probably be available for the treatment of civilians in the areas in which they resided as well as for the treatment of patients in territorial hospitals. But as time went on it was suggested to many of these gentlemen that they should accept the demand for their services overseas. A very considerable number did so, many, of course, being under the military age limit, but some over. From that it could result that the War Office, acting upon the permission given by that acceptance of imperial obligation, might dislocate the services of the various areas, both from a civil and a military aspect; from the civil aspect, because the officers concerned included general practitioners as well as specialists. They therefore put it to the Director-General that in any case these doctors, even if they had accepted the overseas condition, should not be sent abroad without giving the Central Medical War Committee an opportunity of putting the case before him. The Director-General had promised to tell the Committee when he proposed to remove them. Having briefly touched on the question of demobilization along the lines mentioned in the report itself, Dr. Verrall came to what he conceived to be the most contentious item—namely, the payment of medical officers of V.A.D. hospitals. Dr. Howard Marshall, feeling that some of his colleagues were put upon by doing so much work for nothing, urged that they should be remunerated. Dr. Carter, of Cheltenham, also wrote a letter to the D.D.M.S. Southern Command suggesting that such gentlemen should be remunerated. At that time, apparently, Dr. Carter and others—he assumed Dr. Marshall—had become aware of the existence of the order of June 16th, 1915. Seemingly the reply of the D.D.M.S. was sufficient to satisfy Dr. Carter, not as to the non-existence of that order, but to the effect of leading him to do nothing more in the matter between January, 1916, and November of the same year. Although in general members attending V.A.D. hospitals were unaware of the possibility of getting it, payment of 10s. per diem was begun in Aldershot as long ago as August, 1915. Dr. Marshall drew the attention of the Central Committee to the matter in January, 1917. Dr. Verrall detailed the discussion which took place between the Committee and the War Office which led the Committee to express themselves concerning the misunderstanding and irritation which had arisen. He did not think it incumbent upon him to attempt to settle where the blame should be apportioned. It was obvious that it should have been the duty of some authority to see that when the order of June, 1915, came into existence, those attending the V.A.D. hospitals did not remain in ignorance of the possibility of getting payment if they desired it. In that connexion they had a great deal for which to thank Dr. Marshall; he not only ascertained the fact, but he fixed his mind on it, and on behalf of those attending these hospitals pursued it with praiseworthy pertinacity. It was due to him that it came to the knowledge of the Central Committee. It was the desire of the speaker to give Dr. Marshall full credit, because he was now going to turn to another side of the question of which he could not speak so favourably. The *Medical Press and Circular* had been very active in pushing this particular complaint on behalf of the V.A.D. men, but it had also made some remarks about the Central Committee and the Association which it was impossible to pass over. Dr. Marshall had thought it right to circulate a reprint. After depicting what had been done by Dr. Carter and Dr. Marshall the reprint stated that Dr. Marshall's appeals for help to the Central Medical War Committee and the British Medical Association were made, iterated, and reiterated, and nothing was done. That statement was simply not true. It might

be supposed that the Committee was appealed to at an early stage and had refused and had been again appealed to and refused. The fact was that the Committee was not approached at all until January of the present year. It was fair to claim that so far as the Committee was concerned, when approached it had done a great deal, and it was due to nobody else but the Committee in its dealings with the Director-General that the matter was officially set beyond all question, and his opinion obtained and published in the *Journal* of July 7th. The *Medical Press and Circular* also referred to the British Medical Association as being in the hands of a "troop of political posturing and time-serving pantaloons," and added that the Central Medical War Committee was obliged to dance to their piping. "The Central Committee is the untimely and impotent whelp of the Association, a fact which the one does not allow the other to forget." (Loud laughter.) It was a shame, said Dr. Verrall, that this miserable, libellous balderdash should have been printed, circulated, and flung about the country.

Dr. J. H. EWART (Eastbourne): Has that paper been circulated by a private member of the Association?

Dr. VERRALL: I understand it has been circulated with an accompanying letter—I do not know how widely.

Concluding his survey of the report, Dr. VERRALL said that increasing difficulties were found in supplying medical men for the army. The profession must depend upon what the authorities said, but could not go on indefinitely, and the Committee had urged upon the military authorities the importance of making the best use of those medical men they had. In that connexion he referred to the excellent work done by the Local Arrangements Committee under the direction of Dr. T. W. Shore.

Major RUSSELL COOMBE (Exeter) intimated that as a Branch secretary he had received the pamphlet referred to by Dr. Verrall, with a circular from Dr. Howard Marshall asking him to bring it before his Branch. A subscription form of the *Medical Press and Circular* was enclosed.

Dr. L. W. DRYLAND (Northants) moved the following rider:

That, in the opinion of this meeting, all medical officers of V.A.D. and other military hospitals should be paid for their services, such payment to date from their appointment to the hospital.

It was passed, he said, by a very large meeting of the members in the Division, but it was not in any way a criticism of the Medical War Committee. What gave rise to a good deal of indignation was that some men knew about the payment and were receiving money while others had not the information. He approached the county director, who said that the order sent to him was marked "Private and Confidential," and that was why he had not disseminated the news. All the men in the Division did not want to be paid; a large number worked for nothing, and desired to do so—he among them—but it was grossly unfair that some should have the information while others had not.

Dr. HOWARD MARSHALL (Gloucestershire) said that he was not responsible for all that appeared in the *Medical Press and Circular*. He was responsible for sending the reprint round, certainly, in order to give a synopsis of events and the documents. Such things had to be done on the spur of the moment. He took full responsibility for having sent it round (a voice, "Shame"), but he did not agree by any means with the remarks made about the Central Medical War Committee and the British Medical Association. As the Representative of Gloucestershire, he desired to move that the Government be urged to institute an inquiry into the administration of the Army Medical Service in its relationship to civil practitioners.

The CHAIRMAN ruled that Dr. Marshall should speak entirely with regard to the V.A.D. hospitals; he would have an opportunity of proposing his amendment later.

Dr. MARSHALL said that the civil practitioners had always been anxious and ready to do their part for the sick and wounded. But as the war was prolonged from months to years it became evident that a great number of these medical men could not continue their gratuitous services to the hospitals. Why should they do so? When every man and woman throughout the country who was doing war work of any importance received very adequate remuneration, it was merely elementary justice that the

profession should receive payment for services, and even the War Office recognized the principle in the famous letter of authority. He entered into the history of the subject, and referred to the decision of the Representative Body last year, that work on the part of the medical officers to V.A.D. hospitals was fully voluntary, and that to deprive them of this gratuitous labour was opposed to the sentiments of the practitioners employed in those hospitals. He was afraid, however, that the Representative Body did not then make any efforts to find out what were the sentiments and wishes of the medical officers employed. The fact that hundreds of officers at the present time were receiving payment for their services since they had become aware that they were entitled to such payment went to prove that the Representative Body had failed to voice the views of the profession. He detailed the interviews and correspondence which had taken place on the matter, and said that when the Cheltenham doctors sent a deputation to Salisbury to interview the D.D.M.S. on November 16th, 1916, that officer for the first time informed them that they could receive remuneration for their services, and offered a rate of 2d. per occupied bed per day for the hospitals in class B, and 3d. for hospitals in class A. No mention was made, however, of the War Office letter of authority of June 16th, 1915. On March 31st, 1917, the Director-General wrote in the following extraordinary terms: "I am informed that the basis of 3d. and 2d. to which you allude in your letter as having been decided as that on which medical men should be paid for their professional services has no foundation whatever except in the imaginations of idle gossips. No such basis has ever been thought of, and there is no foundation for the statement you have made in your letter." The statements which were thus stigmatized as without foundation were fully borne out by documents in his (the speaker's) possession. Dr. Marshall then said he proposed to read a "private and confidential" letter of June 16th, 1915.

Major TODD inquired whether it was in order for a member to read such a letter without consent; and

Captain FOTHERGILL moved that the letter be not read. This was agreed to.

Dr. MARSHALL, continuing, asked who was to blame for this contemptible treatment of V.A.D. hospitals. Let them go straight to the fountain-head and there they would find a man, the D.G.A.M.S., who was an absolute autocrat and dictator—the only man in the War Office who controlled his department alone.

Dr. C. O. HAWTHORNE (Marylebone) asked whether it was in order to refer to these matters, since the meeting was discussing a simple issue as to whether certain men should be remunerated or not.

The CHAIRMAN said Dr. Marshall was absolutely and entirely out of order. But he had allowed him to go on, wishing to get an unpleasant episode wiped off.

Dr. MARSHALL intimated that as he had not been allowed to read the letter he would say no more.

On the general question raised by the Northants rider,

Dr. TENNYSON SMITH (Bromley) considered that if the V.A.D. staffs had not received the notice referred to, it was solely due to the want of organization in their own county. There had not been a better instance of lack of organization than was shown by the previous speaker's statements. The meeting had been told that a letter came out in June, 1915, and was sent to the county directors, because these were the heads of all the V.A.D. hospitals in their own counties. The county director was solely responsible for the V.A.D. in his command. If there had been the cohesion and sympathy between the county director and staffs in Gloucester that there had been in other counties, this trouble would not have occurred. The Gloucester men should have approached the War Office through their county director.

Dr. C. P. LANKESTER (Guildford) pointed out that the rider included the words "such payment to date from their appointment to the hospital." Many of these appointments preceded June, 1915, which would mean that payment was to be made for a period before such payment was sanctioned. He believed that payment at the rate of so much a day per occupied bed was impossible—"Not at all"—at all events it would lead to confusion.

Lieut.-Colonel D. G. THOMPSON (East Norfolk, Great Yarmouth) said that the confusion arose because the V.A.D. hospitals—or the auxiliary hospitals, which was

the proper name for them—were a Red Cross organization. The War Office paid them a capitation grant per occupied and unoccupied beds; that charge was not for subsistence only; it covered all charges, and it was a question whether the claim of the medical men should not lie against the Red Cross organization. The resolutions might be addressed to the War Office, but they should also be referred to the Red Cross. In acting as civilian medical practitioners at the V.A.D. hospitals the claim was against the Red Cross and not against the War Office at all. In his own area, which was richly supplied with auxiliary hospitals, all the employees of the hospitals—the maids, the porters, the gardeners, etc.—were employees of the Red Cross organization. The War Office undertook a benevolent supervision, but he maintained that it was not at all liable.

Dr. EVAN JONES (City of London) asked why the D.D.M.S.'s did not inform the medical men of the order which went out from the War Office in June, 1915, sanctioning these payments. It was quite clear that Dr. Howard Marshall did not write the offensive paragraph which had been impugned, and he thought a great debt was due to him for bringing the matter forward. The feeling in the City Division was that these medical officers should be paid one shilling a day per occupied bed. Instead of that they had the spectacle of the War Office making "twopenny doctors."

Dr. A. ANGUS MARTIN (South Shields and Tyneside) proposed to add to the rider a clause applying the same principle to attendance on naval patients in civil hospitals. This was seconded by Dr. C. FRIER (Holland and Kesteven), and accepted by Dr. DRYLAND.

Dr. CRAWFORD TREASURE (Cardiff) said that as the mover of the resolution on this subject last year, he was now sorry he did not press it further. The question of the concealment did not touch the point at issue in the rider, which was that these services should be paid for. He wished strenuously to support it.

Dr. SHEPHERD BOYD (Harrogate) commended the action taken by Dr. Marshall in bringing this matter forward.

Dr. H. F. OLDHAM (Lancaster) said that the wording of the rider was a little unfortunate. V.A.D. meant voluntary aid detachment, and they could not logically ask for payment for work called voluntary aid. All these hospitals were registered as auxiliary hospitals, either class A or class B, and if the term "auxiliary military hospitals" instead of V.A.D. hospitals were used it would prevent the introduction of an element of confusion. He moved this as an amendment, and it was agreed to.

Dr. MACDONALD said that he did not think that Dr. Boyd had carried the sympathy of the meeting with him in his commendation of Dr. Marshall so far as the issue of the circular was concerned.

Dr. S. T. LORD (Rochdale) said that there was an honourable compact to deal with these hospitals as voluntary hospitals. A great many men in the country had a conscientious feeling against being forced to accept payment for something which they intended at the beginning should be perfectly voluntary. He knew that there were hard cases, but these should not force the hands of the profession generally. The matter ought to be left to the discretion of individual members.

Dr. C. O. HAWTHORNE (Marylebone) said that the rider was of a very simple character. The delicacy of the position arose from the circumstances. The Representative Meeting had on more than one occasion agreed to and affirmed the general principle that professional work rendered to the nation should be paid for out of national funds. Were they passing a vote of censure on any gentleman who had accepted a position at one of these V.A.D. hospitals? ("No.") The members of the profession, whether wisely or unwisely, had considered that the circumstances justified the acceptance of such positions without payment; it was an individual action. Why when these gentlemen, acting on their individual responsibility, had taken such action should the meeting butt in with a proposal to alter and modify their position? He wished to move an amendment:

That the Annual Representative Meeting, while adhering to the general principle that professional services rendered to the nation should be paid for out of national funds, recognizes that the present position of the medical officers of V.A.D. hospitals has in each instance been arranged by the medical officer concerned, and leaves the continuation or modification of the position to individual action.

This was seconded by Dr. C. E. ROBERTSON (Glasgow), but was lost on a show of hands.

The Northants rider, with the addition proposed by Dr. Martin, was then agreed to, as was a further rider, moved by Dr. EVAN JONES (City of London) condemning the action of the War Office in connexion with the payment of V.A.D. medical officers of V.A.D. hospitals.

Dr. TENNYSON SMITH (Bromley) moved that the remuneration of medical officers of V.A.D. hospitals be at the rate of 4d. a day per bed occupied.

Dr. CHARLES BUTTAR said that the Executive Subcommittee, of which he was chairman, had to deal with three points: (1) It would urge that proper instructions should go from the War Office to all commands as to how these payments should be dealt with; (2) the determination of some settled scale of pay, only to be taken up by such a body as the Central Medical War Committee with the War Office; (3) the question of retrospective application. The Bromley rider was withdrawn.

Expenditure of Central and Local Medical War Committees.

Dr. D'EWART (Manchester) moved:

That this meeting protests against the money of the members of the Association being spent on national and not Association purposes, and by committees over which the Association has no control, and which are composed in part of persons who are not members of the Association.

He said that this was State work, and therefore, on the principle already enunciated, should receive State pay—not State pay for members of the committee, but the State payment of the committee expenses. Every other committee appointed by the Government had had its expenses paid. The figures of expenditure shown in the report were calculated to arouse grave misgiving. The expenses the first year were £664; he was willing to give the Government that. For the second year they were multiplied by four—£2,704—and this year already over £3,000 had been spent. He drew attention to the geometric progression, and asked whether the Association could afford it. Manchester was inclined to think that it could not.

Dr. MACDONALD said that there had been a great deal of misrepresentation of the resolution passed by the Representative Meeting when in Sheffield; that resolution was that patients who were State aided should not be treated voluntarily without payment. The mover could not claim that as an argument to prevent the Central Medical War Committee from spending a certain amount of money. The work it was doing was a national work which ought to be done, and he trusted that, having put their hands to the plough, they would not look back.

Mr. BISHOP HARMAN (Marylebone) denied the statement that this was the only committee doing Government work which did not have its expenses paid. He had a document issued by the Local Government Board in July, 1917, with regard to a Dental Service Committee, and the third item stated that the British Dental Association should place at the disposal of the Committee such clerical assistance as might be necessary, and that no part of the expense of the work of the committee should fall upon any Government department. That did away with the generality of the statement that their own was the only committee which was paying its way. Was it conceivable that a committee which was controlled by the Government could have made such a bold statement as the Central Medical War Committee had made to the Secretary of State for War in April last and have brought him so promptly to reason?

The amendment was lost, as was a further amendment by Manchester that no grants from Association funds be made to Local Medical War Committees for 1917.

Dr. AGNES ESTCOURT-OSWALD (North-East Essex) said that it was in no spirit of criticism she brought forward the following rider on behalf of her constituency:

That the expenditure of the Central and Local Medical War Committees be published, and that a definite opportunity be provided for non-members, who have so largely benefited by this expenditure, to take their share of the burden.

North-East Essex felt sure that the Central and Local War Committees had done their work very well. Practically every doctor in the country had benefited, and not only the doctors, but the general community. Those who had been in any other country during the war realized the fearful condition in which the civilian population in those

countries was placed at one time with regard to medical assistance. That this country had never suffered in that way was due to the fact that the Government was able to treat with an association such as the British Medical Association. Yet there were some doctors in this country who did not belong to the Association, although they derived enormous benefits from it. This rider was intended to urge upon all present to do everything in their power to bring every doctor in each locality into the fold, so that they might be able to present a fully united front in the terrible days ahead. The future struggle was likely to be greater than anything they had gone through in the past.

The rider was agreed to.

Railway Fares Concession.

Dr. A. O. HOLBECH (Worcester) moved that the Central Medical War Committee be instructed to obtain similar treatment with regard to railway fares for members of Local Medical War Committees to that obtained in the case of the Central Committee.

Dr. VERRALL said that this would be kept in mind; but he could not pledge that the Committee would be successful.

The rider was agreed to.

ORGANIZATION OF ARMY MEDICAL SERVICE.

The meeting had before it riders by the North Wales Branch, the City of London, and Gloucestershire, urging an inquiry into the administration of the Army Medical Service.

Dr. VERRALL said that on the previous day a conjoint meeting of the Central Medical War Committee and the Committee of Reference had decided to take a certain line, and the CHAIRMAN suggested that the matter should be left in their hands.

Dr. BUIST (Dundee) moved that the matter be referred to the Council, who would in turn refer it to the Committee.

Dr. CHARLES BUTTAR said that he wanted the Representative Body to be a shade more definite in referring these propositions to the Council. Everybody must be convinced that there was something wrong in the relation between the Army Medical Service and the civilian profession. He had himself suggested all along that that difficulty was entirely due to lack of proper co-operation between the military and civil bodies. He would like to see the meeting pass such a motion as this:

That the Representative Body is not satisfied that the relationship between the Army Medical Department and the civilian profession is on a proper footing, and therefore the Representative Body authorizes the Council to take such action as it considers desirable with a view to improving such relationship.

Dr. W. M. CROFTON (Dublin) seconded.

Dr. E. O. PRICE (North Carnarvon) asked how the meeting could express itself as not satisfied without having first made inquiry. He supported the proposal to leave the matter entirely to the Council.

Mr. BISHOP HARMAN (Marylebone) said that the Committee was practically at the end of its tether in supplying any considerable number of doctors in response to army demands. It was the duty of the Central Medical War Committee to report that to the War Office.

Dr. EVAN JONES (City) said there were abundant grounds for inquiry. Some of the men who had come back from abroad said that the average work they had to do occupied ten minutes a day. Better work would have to be made of the men already in the army.

Dr. W. J. YOUNG (Cambridge and Huntingdon) thought it quite time that some such inquiry should be made. This was the third occasion on which the subject had been before them.

Lieut.-Colonel DECIMUS CURME expressed the belief that an inquiry would tend to soothe the discontent so very prevalent. The services of men in private practice were not utilized to the extent they might be. In his own area he had heard numerous complaints that men had offered their services to take charge in camps in their immediate vicinity and had been refused.

Dr. Buttar's amendment to Dr. Buist's proposition, when put to the meeting, was lost. Dr. Buist's proposition that the whole of the riders expressing the opinion that the Government be urged to institute an inquiry should be

referred to the Council, on the understanding that the Council should refer it to the proper committee, was then carried. The Chairman took a further vote of the meeting on the simple point as to whether there should be an inquiry. The vote of the meeting, almost unanimously, was in favour of an inquiry, and the CHAIRMAN said that this clear vote would be valuable to the Central Medical War Committee.

MEDICAL PATRIOTIC FUND (LOAN FUND) SCHEME.

MR. BISHOP HARMAN moved (on his own responsibility and not as Representative of Marylebone):

That this meeting of the Representative Body approves the principle of the Medical Patriotic Fund (Loan Fund) Scheme, and instructs the Council to launch the scheme on the cessation of hostilities, unless in the meantime amalgamation or co-operation of existing funds shall render the establishment of an independent fund unnecessary or undesirable.

He described the scheme propounded by the subcommittee of which he was chairman. The object of the fund was the protection or assistance of those who went to the war and came home to find themselves in temporary difficulties. Loans not exceeding £500 to any one man should be made from the fund. The psychological moment for the launching of such a fund was at the cessation of hostilities.

Major D. F. TODD (Sunderland) seconded, but thought that if a co-ordination of the various funds could be brought about their position would be strengthened.

Captain FOTHERGILL moved to omit the words "on the cessation of hostilities," and Dr. A. P. TRINDER (East Cornwall) thought that the words "in the meantime" must also be omitted.

Dr. MACDONALD said that these amendments had altered the position entirely. Mr. Bishop Harman's rider, as it originally stood, gave the Council time to think. He did not believe there was much chance of the benevolent bodies amalgamating for the purpose of carrying out the scheme.

Captain Fothergill's amendment was lost, but an amendment by Dr. A. E. CORE (Westminster) was carried, that after the words "cessation of hostilities," the words "or earlier if the need arise," be interpolated.

Dr. MACDONALD moved a further amendment, which was carried, that the words "consider and if approved to" be inserted after the words "Council to."

COMMISSIONS FOR MEDICAL MEN OVER MILITARY AGE.

Dr. EVAN JONES (City) moved:

That this Representative Body is of opinion that it is unfair to refuse to British civilian medical men over military age, doing whole-time service, commissions that are now being offered to American non-registered doctors.

He said that American doctors doing work in military hospitals were being offered commissions, although not on the *British Register*, on exactly the same terms that were refused their own men ever since they had been doing that work.

After a brief discussion, the motion was withdrawn.

FUTURE SHORTAGE OF MEDICAL MEN.

Dr. NOY SCOTT (Plymouth) moved:

That in the opinion of the Representative Meeting no bona fide medical student should be conscripted for military service until he has completed six years of medical education; but on obtaining a legal qualification as a medical practitioner should automatically join the military or naval service.

Dr. VERRALL said that the question of the time at which a medical student should be taken from his work had been a very difficult one. At the beginning no doubt action was taken for two reasons: in the first place on account of the shortage of officers, and of the fact that these young men were of physique and capacity which would ensure the making of good officers; and in the second place, it was done in ignorance of how long the war would last. It was a balance as between the supply of doctors for the future by the retention of students on the way to qualification and, on the other hand, the absolute necessity for a certain number of medical officers for the army. If the proposition before the meeting were passed, it must be passed as a general expression of opinion.

A motion to proceed to the next business was carried.

THE RECRUITING MEDICAL BOARDS.

Dr. VERRALL said that the Council realized that there was a feeling throughout the country that some of the medical boards had not done their work in the best possible fashion, and the Council thought it wise to appoint a small committee to watch the matter. In view of the change of policy announced two days previously by Lord Derby, things had come to a head. The matter came forward at the joint meeting on the previous day between the War Committee and Committee of Reference, when it was decided to propose that the selection of the doctors to serve on the medical boards should not be left wholly in local hands, but should be supervised by some central body, and that the selection should be made under the auspices of the Committee of Reference and the Central Medical War Committee, who were preparing a scheme. If the recruiting medical boards were to be placed in civilian hands, those civilian hands should not be solely those of the Local Government Board. In the future some medical advice locally, supervised by some central advice, should be the basis of the formation of these boards.

Dr. MACDONALD, as Chairman of the Committee appointed by the Council to deal with this matter, endorsed what Dr. Verrall had said.

A Representative maintained that the civilian medical practitioner's knowledge of the needs of the army and of the duties which the recruits would be called upon to perform was very slight. He urged the meeting to express the view that there should be some connecting link between the War Office and the proposed civilian organization.

Dr. VERRALL said that it was impossible to escape a certain danger either way. The pendulum would swing from one side to the other according as the civil practitioner's or the military officer's point of view predominated. In any case, the opinion of the local profession should be taken as to the best men to act on these boards, and there should also be some central authority to co-ordinate the various opinions. He took it that on all boards provision would be made for the army medical point of view being properly put, so that when a man was classified by civilian doctors it should be possible for those classifying him to do so with full knowledge, perhaps through a military medical assessor, of what the classification entailed.

Major TODD moved that the action taken by the Committee be approved, and this was seconded by Dr. JOHNSON SMYTH.

Dr. HAWTHORNE, in supporting the proposal, said that he did so upon the understanding that it did not mean agreeing to a proposition that the special central body was to be charged with the selection of members of medical boards in particular districts.

The CHAIRMAN said that there was no question of the Central Medical War Committee attempting to say who was to be selected for the recruiting boards in any locality.

Major Todd's proposition was carried.

Sir T. E. FLITCROFT (Bolton) suggested that the Local Medical War Committees would be of service in the appointment of medical boards.

The CHAIRMAN said he knew that this was the procedure at Bolton, which had one of the best medical boards in the country. In moving the reappointment of the Central Medical War Committee for 1917-18 with the same personnel as for 1916-17 the Chairman paid a warm tribute to the members of the Committee, who had given much time to the work.

The motion was carried with acclamation.

THE LATE DR. HACKMAN OF PORTSMOUTH.

Dr. JAMES GREEN made an appeal, which was supported by Dr. D. A. SHEAHAN, on behalf of the family of the late Dr. Hackman of Portsmouth, who after spending himself to the full in professional labours and in work for the Association, had died leaving a widow and large family unprovided for. The sum of £500 or £600 had been raised locally in the Portsmouth Division.

[A letter from Dr. James Green with a list of subscriptions will be found in the body of the *JOURNAL*, p. 166.]

PREVENTION AND TREATMENT OF VENEREAL DISEASE.

Remuneration for Clinical Posts.

Dr. GARSTANG, Chairman of the Medico-Political Committee, moved the adoption of Recommendation A of Council (SUPPLEMENT, May 5th, pp. 86-8, para. 64), and this was agreed to.

Dr. TISDALL (Liverpool) moved the omission of subparagraph (iii), but this was lost; as was another amendment from the same source, to the effect that the handing on of the treatment of venereal diseases to general hospitals favoured the practice of medicine by companies and corporations.

The CHAIRMAN said that the handing on of the treatment to general hospitals had been followed all over the country for the last eighteen months.

Dr. CRAWFORD TREASURE moved that in Recommendation A, subparagraph (viii) (c), the words "and should work under the supervision of the honorary staff" be deleted.

Mr. BISHOP HARMAN (Marylebone) said that if they did not work under the supervision of the honorary staff they would be under the supervision of the lay board.

The amendment was lost.

Dr. TISDALL (Liverpool) moved that the "proportion" mentioned in subparagraph (ix) of paragraph 64 should be settled by some central authority.

Mr. BISHOP HARMAN said that the objection rose from a misapprehension. The staff who ran these places would be paid, but certain work would have to be done by the regular honorary staff of the hospital who would be called in, and it was impossible to assess centrally the monetary value of their work. That must be agreed upon locally according to the work done.

Dr. MACDONALD said that the variation in different districts was great, and unless men with local knowledge were available for settling the proportion there would be confusion.

The amendment was lost.

Dr. GARSTANG then moved Recommendations B and C (p. 88, para. 65), and these were agreed to. On Recommendation D, which set up a scale of remuneration for part-time senior medical officers of clinics and differentiated between London and the Provinces, some discussion took place.

Major TODD (Sunderland) asked the reason for the difference between London and the provinces.

Dr. GARSTANG said that conditions were so different that a uniform scale of fees was out of the question.

Mr. BISHOP HARMAN justified the distinction between London and provinces on the ground that the hospitals in London were generally at a greater distance from the practitioner's residence and that pressure of work was heavier in the London clinics.

The CHAIRMAN said that they were now discussing a matter which, if carried by a two-thirds majority, would be the policy of the Association, and there was some danger of getting into a morass when fixing the fees.

Major TODD and Dr. OLDHAM (Lancaster) maintained that it would be a great mistake to make a difference between the provinces and London.

Dr. MACDONALD thought that an error was possibly being made in fixing any fee at all. On his motion it was agreed to delete the distinction between London and the provinces, and to recommend the scale to Divisions as a guide in their negotiations with local authorities. This was seconded by Dr. E. J. DOMVILLE (Exeter).

Dr. PRICE (North Carnarvon) said that every one felt there was a great advantage in having a fixed fee; it gave a kind of backbone to the invertebrate people in the provinces.

Lieut.-Colonel R. A. BOLAM said that he had had a great deal of personal experience with regard to the difficulties arising in these scales of fees. There were difficulties with regard to any scale. He was in sympathy with the Chairman of Council leaving it to local option, but it would surely be a great advantage to have a scale to fall back upon of which it could be said that the Association considered it fair.

An amendment—

That no advertisement of an appointment at a less rate than 2ls. per hour be accepted for the BRITISH MEDICAL JOURNAL,

—moved by Dr. BUIST, was withdrawn, Major LUCAS stating that this must be opposed under certain circumstances.

The CHAIRMAN said that he thought the matter of advertisements might well be entrusted to the Journal Committee.

Dr. JOHN STEVENS moved that no advertisement be accepted for such offices without the approval of the local Branch of the Association, but withdrew his amendment on the CHAIRMAN pointing out the impracticability of such a suggestion.

After further discussion the Recommendation was accepted in the following form:

That the following scale of remuneration for part-time senior medical officers of clinics . . . be approved and recommended to Divisions as a guide in their negotiations with local authorities:

	Per session.
For one or two sessions per week, not exceeding two and a half hours each	£3 3 0
For three or more sessions per week, not exceeding two and a half hours each	£2 12 6

Recommendations E and F of the same report, dealing with the remuneration of clinical assistants, were also carried, with an addition to the latter fixing £250 as the salary for a resident assistant.

[On the following day there was some fresh discussion on Recommendation E, when it was moved that the standing orders be suspended to allow it to be reconsidered.]

MINISTRY OF HEALTH.

Central Organization.

Dr. T. W. H. GARSTANG proposed:

That Recommendation G 1 of Council (SUPPLEMENT, May 5th, p. 89) be adopted:

That a Ministry of Health should be created to take over from existing Government departments such duties as are concerned with the health of the community and to deal with those duties only.

Dr. Garstang explained that the matter originated in a Subcommittee of the Medico-Political Committee, but it was taken out of their hands and placed in the hands of a special Subcommittee of the Chairmen's Committee which did the principal work in arriving at that scheme, which was afterwards confirmed by the full Chairmen's Committee and went through to the Council.

Dr. J. A. MACDONALD said the resolution was merely an opinion if passed. The idea of a Ministry of Health was no new one. It had been before the profession for a good many years, and had been endorsed by different meetings of the Association. The matter was restarted in January, 1917, when, in consequence of various newspaper reports and other information received, the Medico-Political Committee thought it necessary to get into communication with the Local Government Board on a matter concerning maternity and child welfare. They were informed officially by a letter that there was nothing in the air at the time, and the matter dropped for a while. Later they found that the thing was going on, in spite of the information officially conveyed. They found it necessary to press for an interview with the President of the Local Government Board to find out the position of affairs, and give him their views whilst such were likely to be of any possible good. On March 16th a deputation went to Lord Rhondda. It was then that he brought forward the question of the Ministry of Health. Up to that moment it had not been in their thoughts or intentions; they were dealing with a comparatively small department of it. Lord Rhondda told them two important things—first, that he would be very glad to have their opinions and observations, and second, that if they had any such to offer they must be offered within a very short period, because his bill was practically drafted. He gave the deputation the idea that it had almost reached the point of being accepted by the Cabinet, with every probability of its becoming an Act of Parliament in a very short time. It was under the stimulus of that obvious necessity that the matter was taken up by the Special Committee. They met four times. He was not going to say whether the scheme was a good one or a bad one, but he would point out that if the Association, through those committees, had not done its best to have something to lay before Lord Rhondda, the profession would have been at the mercy of a bill introduced by him on the advice of the medical staff of the Local Government Board.

Dr. J. McCREA (Reading) moved as an amendment:

That this meeting, although in favour of the formation of a Ministry of Health, is of opinion that the Council of the

Association has exceeded its powers and has entirely neglected the opinions of the members in formulating a scheme and placing it before the Government without previous consultation, and that the consideration of the details put forward in the said scheme is therefore premature and futile.

Dr. McCrea, in proposing the amendment, said the matter was one which was going to create a revolution in the whole practice of the country. The Medico-Political Committee of the Association seemed to have been "had." Where was the urgency? Had a bill been drafted or introduced? The whole matter probably had been shelved never to be heard of for two or more years. In the meantime the Prime Minister had in his possession a scheme of which the medical profession had not approved.

Dr. GARSTANG explained that when the scheme was sent to the President of the Local Government Board he was told that it was the scheme of a committee of the Council but not of the Representative Body, and that it would not be the scheme of the Association until it had been considered by the Representative Meeting in July.

Dr. J. A. MACDONALD said that what Lord Rhondda did say was that he had a scheme going forward and was anxious to have their opinion. But Lord Rhondda did not have a chance to get on with the scheme, for there was a power behind him—the approved societies—who did not see their way to have the scheme carried out because it was likely to take away the power they had under the Insurance Act. Accordingly Lord Rhondda was promoted to be Food Controller. But a scheme was going on, much more dangerous than the one suggested. The Local Government Board was going to be the body to run the Ministry of Health, and he did not think, unless they were careful and worked together, they were going to get a scheme better than the one which the Council suggested.

Dr. HUGH SNELL (M.O.H. Coventry) said that a Ministry of Public Health was coming. He was sure the Representative Body would endorse the moderate resolution before it from the Council. He thought it would be wise before expressing the opinion of the meeting to find out what the Local Government Board proposed, and not put the Association on wheels to be pushed into nationalization or municipalization of medical service.

Dr. H. B. BRACKENBURY (London) said there had been some confusion between two bills. The situation with which they were faced in March was not that there was a bill ready to be introduced into Parliament establishing a Ministry of Health, but that there was a bill of one clause ready to be introduced, which would have been introduced already if it had not been for Lord Rhondda's removal from the Local Government Board—a bill giving the Board power to do whatever it liked by order in connexion with the health of mothers and young children. They were further informed that the bill of the Local Government Board was to urge every county council and town council to establish centres for the extension of this work. Further, there was a suggestion from very high quarters, though not from the Board, that that work in connexion with maternity and child welfare was going to be extended into the domiciliary treatment of mothers and children. Where would the Representative Body have been if the Council had done nothing? The only remedy they could suggest was the unification of the departments dealing with public health, so that there should not be the putting of a part-time or whole-time officer over the families of their private or insured patients. If there was one thing which the scheme was not and was not intended to be, it was a scheme of State medical service. It was the best remedy that the Council could put up to prevent a part-time or whole-time salaried clinical service being set up against the considered opinion of the profession.

In reply to various questions as to the "high quarters" from which information had been received as to the extension of maternity and child welfare work, the CHAIRMAN said that all information received was laid before the Committee.

The amendment by Dr. McCREA (Reading) was put and lost.

The following amendment and rider, by Oldham and Reading respectively, were withdrawn:

That in the first and second lines of the Reading amendment contained in Item 67 of the Agenda (p. 9), the words "although in favour of the formation of a Ministry of Health" be deleted.

Rider by Reading, in the event of foregoing amendment being carried:

That this meeting pass a vote of censure on the Council for putting a scheme for the creation of a Ministry of Health before the Prime Minister, before consulting the profession, and is of opinion that it goes far beyond the creation of a Ministry of Health, and is practically a scheme for State medical service.

Dr. J. McCREA asked leave to make a personal statement. He was chairman of the meeting at which the Reading resolutions were passed, and was elected as their representative, and had loyally carried out his duties, but he did not agree with either resolution.

Dr. W. BLAIR (South-Eastern Counties, Edinburgh Branch) moved the following amendment:

That the Representative Body protests against the action taken by the Council, without previously obtaining the authority of the Divisions, in respect of the Ministry of Health suggested by the Government.

Dr. Blair said the matter was placed before the Divisions with no explanation whatever as to the reason for the urgency of the proposal by the Council. He was instructed that if the explanation which the Council gave seemed to him sufficient he was to support the Council, but he was not yet satisfied.

Dr. F. L. POCHIN (Oldham) said he hoped the amendment would not be passed, because, after the explanation they had heard, it was obvious that the Council was rushed into action against its will. They went to Lord Rhondda thinking of anything but a Ministry of Health, and suddenly Lord Rhondda sprang upon them the information that the bill was almost before the House establishing a Ministry of Health, and asking for suggestions.

Dr. D. A. SHEAHAN (Portsmouth) said he came up very much incensed against the action of the Council in usurping what he thought was the function of the Representative Body, but after the explanation from Dr. Garstang he thought the Council would have failed in its duty if it had not done something, and he thought it did very well in the circumstances.

Dr. W. H. IRVIN SELLERS (Preston) said they were in favour of the establishment of a Ministry of Health. It was utterly impossible at present to define all the details or the exact attitude they might take towards it, but such a Ministry was essential to the future of the country.

Dr. H. F. OLDHAM (Lancaster) supported the Council in its action, without committing himself to the details of the scheme. He regarded the scheme as the means of escape of the Association from two great dangers. The Local Government Board was making every effort to take possession of the entire department of National Health in the kingdom. Against this were the Insurance Act Commissioners, who wanted equally to control all arrangements for the health of the country, and the Commissioners, they knew, were controlled by the approved societies. The most successful solution was the Ministry of Health, which would control both. That the Council had the foresight to see that was greatly to their credit.

Dr. D. A. SHEAHAN (Portsmouth) said he, too, was instructed by his Division to support the promotion of the Ministry of Health. Anything that would get rid of two autocratic bodies would have his sympathy and approval.

Major R. WALLACE HENRY (Leicester and Rutland) said he was sorry the Divisions had not before them the information given by Dr. Garstang. They would not then have felt that the matter had been rushed. It seemed to him that the necessity of pressing on with the matter had passed away with Lord Rhondda's removal to another sphere. With so many men abroad, he did not think the Representative Meeting should express strong opinions one way or the other, or make the Ministry of Health the policy of the Association.

Dr. J. A. MACDONALD (West Somerset) wanted to disabuse the mind of Major Wallace Henry that the danger was over. It was not; it had taken on a more objectionable form—that of a stronger development of the Local Government Board, which was still more highly dangerous than a form of Ministry of Health of which they would not approve. He was sorry that there was not a fuller explanation in the report of the Council of what was the difficulty which induced them to act in a hurry. He could only say on behalf of the Council that it was an oversight.

The South-Eastern Counties amendment was lost, and the CHAIRMAN then put the resolution:

That a Ministry of Health should be created to take over from the existing Government departments such duties as are concerned with the health of the community and to deal with those duties only.

The resolution was carried with one dissentient.

Friday, July 27th.

The proceedings were resumed on Friday, July 27th, at 9.30 a.m. Mr. E. B. TURNER (Chairman of Representative Meetings) was in the chair. The minutes of the previous day's meeting were corrected and confirmed.

THE REMUNERATION OF PART-TIME CLINICAL ASSISTANTS UNDER SCHEMES FOR DEALING WITH VENEREAL DISEASE.

Lieut.-Colonel R. A. BOLAM moved the suspension of the standing orders to consider a resolution passed on the previous day, that the remuneration of part-time clinical assistants of clinics set up under schemes for the diagnosis and treatment of venereal diseases should not be less than one guinea per session not exceeding two and a half hours.

Major ALBERT LUCAS seconded. The effect of the motion passed on the previous day was that if a clinical assistant—perhaps a man who had only just qualified—went down to the hospital for five or ten minutes, he would have to be paid a guinea. In most cases he thought a guinea quite a minimum fee, but there were instances in which a stringent rule of a guinea a session would be undesirable. He wished the sum recommended simply as a guide.

Dr. H. B. BRACKENBURY considered that the resolution passed on the previous day was one of the bedrock things upon which the Representative Body must continue to make a stand. In connexion with clinics of other kinds it had never hesitated to do so. The time covered by the fee was not to exceed two and a half hours. If a local authority or hospital was so foolish as to arrange a session only lasting ten minutes, the scheme was faulty, either because the work was not properly arranged or because there was not enough work to do. There might be some cases in which the fixed fee was unfortunate, but having settled the principle, he hoped the Representative Meeting would again endorse it.

The CHAIRMAN said that the motion was strictly that the standing orders should be suspended, but he had allowed both sides to speak on the general question in order to save further debate. He then put the motion to the meeting, and declared it lost.

(To be concluded.)

ANNUAL GENERAL MEETING.

THE eighty-fifth Annual General Meeting of the British Medical Association was held in the Connaught Rooms, Great Queen Street, London, on Friday, July 27th, at 2 p.m. Sir CLIFFORD ALLBUTT, President of the Association, was in the chair.

THE PRESIDENT said that he wished to thank the members very cordially for again electing him as President. He had received some very valuable information from the offices of the Association from time to time, but on one point he had received no information whatever—namely, as to the possibility of the war being over within any calculable future period. That being the case, he could not say anything about the arrangements for the next summer. He could only hope that it might be possible for the Association to meet in Cambridge, and Cambridge would be only too thankful, impoverished though the university was, to receive it.

APPOINTMENT OF AUDITORS.

Dr. G. H. LODGE moved, and Dr. J. P. CARTWRIGHT seconded, and it was agreed to, that Messrs. Price, Waterhouse, and Co. be reappointed auditors of the British Medical Association at a remuneration of one hundred and fifty guineas.

AWARD OF MIDDLEMORE PRIZE.

The PRESIDENT announced that the Middlemore prize for 1917 had been awarded to Captain William Clark

Souter, M.D., R.A.M.C.(T.F.), of Aberdeen, for his essay on "Disorders of the eye and of its functions induced by war injuries not directly affecting the eye." He said that unfortunately Captain Souter was not able to be present, and in his absence Dr. Adams, the Chairman of the Scottish Committee, would accept the award on his behalf. The President handed the prize to Dr. Adams.

THE PRESIDENCY: THE NEXT ANNUAL MEETING.

Mr. E. B. TURNER, Chairman of Representative Meetings, said that he had to report that the Representative Meeting, on the recommendation of the Council, had re-elected Sir Clifford Allbutt as President for the ensuing year. He did not need to say anything with regard to the advisability of such a proceeding, nor of the pleasure and pride with which the meeting had assented to the nomination. Sir Clifford Allbutt was entering on the second year of his presidency, and he had not yet paid the price of it—he had not yet given his presidential address. Every member of the Association, every scholar and gentleman within it, would like to have the opportunity of listening to that address, and it was possible, even if the optimists were still flattened in the dust, that next year that meeting might be held in Cambridge instead of London, and then they might have the presidential address as well as an address or two in medicine and surgery, though not the sections—in fact, they might have the ghost, the shadow, the dry rattling bones of an annual meeting, which, however, would be lightened by the address given them under those circumstances by the President. No member of the Association wished to "sponge" on the hospitality of Cambridge University, which had so grandly risen to its duty in the war. But they would like, paying their own expenses, to go there, if Cambridge would be their nominal hosts. He had formally to report the election of Sir Clifford Allbutt as President for 1917-18.

The announcement was greeted with loud applause, members rising in their places.

THE PRESIDENT said that he was very grateful for the more than welcome way in which they had received the report of his re-election. He had thought it just possible that some fraction of the cordiality with which they had re-elected him on that occasion might be due to the fact that they would not have to sit for three-quarters of an hour under a presidential address; they might be rather thankful that that was postponed, he would not say to an indefinite future, because he thought the Chairman of the Representative Meetings had made a good suggestion which might well be acted upon, and which had not occurred to him. If the circumstances of the war were still adverse, or at any rate if the war had not concluded, they would be only too glad to consider that suggestion. The Representative of the Cambridge and Huntingdon Branch was present, and, subject to his frowning eye, which he did not see, he (Sir Clifford) thought the suggestion rather attractive if they were able to do no better, though he hoped they would be able to do better.

Dr. W. J. YOUNG, the Representative for Cambridge and Huntingdon, said that he would certainly do his part to bring the matter before the Division, and he hoped the suggestion would mature, subject to the strict condition that such a meeting did not take the place of the proper visit which they hoped to obtain by and by.

The business of the annual meeting then concluded.

Meetings of Branches and Divisions.

NORTH WALES BRANCH.

The annual meeting of the North Wales Branch was held at University College, Bangor, on July 18th.

Election of Officers.—The following officers were elected:

President: Dr. Drinkwater. *Vice-President:* Dr. H. Jones Roberts.

Joint Honorary Secretaries: Dr. H. Jones Roberts, Dr. J. R. Prytherch.

Medical Arrangements in Mesopotamia.—The meeting congratulated Lieut.-Colonel Carter, I.M.S., on his courage in reporting so candidly and fearlessly upon the grave position of army medical affairs in Mesopotamia.

Insurance Advisory Committee.—It was resolved to support the nomination of Dr. Hugh Jones (Dolgelly). It was felt that rural Wales and sparsely populated rural areas demanded representation. The interests of practitioners in industrial areas and South Wales cities were, it was considered, already safeguarded, seeing that the conditions of practice were the same as in English areas.

Public Health Laboratory.—The meeting pledged itself to support the establishment of a public health laboratory in connexion with the University.

Proposed Ministry of Health.—The report with reference to the Insurance Act and future legislation, including the proposed Ministry of Health, was considered. Dr. Hugh Jones (Dolgelly) gave a review of the position and referred to the need of improving the Insurance Act in certain details, particularly in rural areas; he considered that the Act was an improvement on the old club system.

Treatment of Fractures.—Dr. A. NORMAN LEEMING (Colwyn Bay) read a paper on further cases of fracture treated by Lane's plates and screws, which he illustrated by x-ray photographs; this was followed by a discussion in which many members took part.

SHROPSHIRE AND MID-WALES BRANCH.

The spring meeting of the Branch was held on July 3rd, when Dr. GEORGE MACKIE was appointed President. The Branch Council was re-elected with the exception of Drs. J. P. Cartwright and W. J. Orr (retired by rotation), and Lieutenant R. J. Urwick (resigned), who were succeeded by Drs. J. W. Riley, T. M. Cuthbert, and R. D. Stawell. Dr. J. Cartwright was re-elected Representative for Representative Meeting.

Insurance Acts.—Dr. CUTHBERT read a report from the joint Panel Committees. On the whole the present system was approved, but it was suggested that mileage should be considered in country areas.

Local Medical War Committee.—Dr. SANKEY gave an account of the work of the Local Medical War Committee.

INSURANCE.

LOCAL MEDICAL AND PANEL COMMITTEES.

WESTMORLAND.

At a recent meeting of the Westmorland Panel Committee the following resolutions were adopted:

1. That an insured person (not being a temporary resident) whose medical card is not transferred after one week's residence in a new area, to a doctor in that area, if applying for treatment, be not entitled to medical benefit by a doctor in that area for a period of a fortnight. It is suggested that this be added (in red ink) to the instructions printed on medical cards.
2. That an insured person (other than a temporary resident) not having his or her medical card signed by a doctor within one week after becoming otherwise eligible for medical benefit, if applying for treatment, be ineligible for medical benefit for a fortnight.

RENFREWSHIRE.

At a meeting of the Panel Committee on July 2nd it was reported that the Insurance Committee had adopted the scheme of the Panel Committee for medical referees. The Executive Committee was instructed to divide the area into districts and to submit a panel of referees. It was decided to nominate Dr. Hill for appointment on the Insurance Acts Subcommittee for Scotland.

INSURANCE NOTES.

SANATORIUM BENEFIT.

THE Insurance Committee for the county of Ayr, in a report on the administration of sanatorium benefit in its area during 1916, states that 262 applications for benefit were received, 135 being from insured persons and 127 from dependants. Of the total number, 174 were sent to sanatoriums, 60 to hospitals, and 12 were treated at home, while 10 died before treatment could be commenced, and 5 were refused for various reasons. The numbers sent to sanatoriums have increased each year since the Act began, and the same applies to those sent to hospitals, while those treated at home have decreased from 41 in 1914 to 12 in 1916. Careful inquiries have been made into the housing accommodation of the applicants, and it was found that about 74 per cent. lived in houses of only one or two apartments. In the two-roomed houses there were on the average 5.73 persons per house, the average for the county being 4.85, while the death-rate was 26.64 per cent. as compared with the average

for the county of 20.57. From a classification of trades it appears the miners yielded 14 patients, mill workers 13, domestic servants 11, and labourers 10. There were 32 applications from married women and 65 in respect of children of school age, which accounts for 77 per cent. of the applications from dependants. There has been a steady and gratifying increase in the number of persons whose health is good after treatment under the committee, and a number of them are now serving in the army abroad, and report themselves as in good health. It is hoped to inaugurate an after care committee during the present year. The information which the committee has been able to collect about the housing accommodation of the patients shows how important this factor is. The report expresses the opinion that "the sooner insurance committees obtain wider and fuller powers the better it will be for the nation."

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty:—Fleet Surgeons J. Shand, M.B., to the *Victory*; F. J. A. Dalton to Portland Hospital. Staff Surgeons J. J. H. Rooney and A. H. Davidson to the *Pembroke*. Surgeons B. Taylor to the *Patrol*; F. St. B. Wickham to the *Fivid*, additional. Temporary Surgeons J. D. Bangay to the *Fivid*; J. H. Newmarch, M.B., S. L. Higgs, A. R. Matheson, M.B., A. T. Woodward, M.B., to the *Fivid*, additional for Plymouth Hospital; A. G. Bee, T. S. Duncan, M.B., to the *Victory*, additional for Haslar Hospital; C. S. Owen to the *Sapphire*; S. D. Kilner to the *Colossus*, vice Martin; H. O. Martin to the *Eurymachus*, vice North; G. G. Menbery, M.D., to the *Fivid*, additional. To be temporary Surgeons: L. G. Higgins, A. M. MacGillivray, W. W. Forsyth, H. A. L. Guthrie, W. M. Fairlie, M.D., A. L. Abel, J. M. Tyrrell, M.B.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Probationers C. Holmes to the *Harry*, H. A. Morton to the *Hydra*, J. B. Whiteford to the *Zephyr*, W. E. Johnston to the *Cynthia*, R. E. Joyce to the *Falcon*, G. L. Bell to the *Fame*, W. H. Miller to the *Fervent*, H. I. Palmer to the *Garry*, T. B. Feick to the *Gipsy*, H. S. Little to the *Grasshopper*, K. T. H. Davies to the *Greyhound*, W. I. Cryderman to the *Acorn*, W. A. Dafoe to the *Ambuscade*, W. P. Hogarth to the *Alarm*, H. I. Quinn to the *Conflict*, F. C. Speechley to the *Kangaroo*, C. Shaw to the *Kestrel*, W. P. Wilson to the *Wizard*. To be Surgeon Probationers: A. H. Hall, D. J. Whitton, R. C. Shaw, A. Roe, J. Macfarlane, W. C. Holdsworth, G. McCoull, J. L. Coventry, F. C. W. Capps.

ARMY MEDICAL SERVICE.

Colonel C. A. Lane, M.B., is retained on the active list and to be supernumerary.

Lieut.-Colonels to be temporary Colonels whilst employed as Assistant Directors of Medical Services of a Division: G. St. C. Thom, C.M.G., M.B., J. W. H. Houghton, M.B. (Substituted for the notification in the *London Gazette* of April 28th.)

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel J. D. Ferguson, C.M.G., D.S.O., to be temporary Colonel whilst specially employed.

Temporary honorary Lieut.-Colonel C. H. Fagge, M.B., F.R.C.S. (Major R.A.M.C.T.F.), relinquishes his temporary rank on reposting, May 30th. (Substituted for the notification in the *London Gazette* of May 29th.)

Majors to be acting Lieut.-Colonels whilst holding the appointment of Assistant Director of Medical Services of the Army: P. Davidson, C.M.G., D.S.O., M.B., W. F. Tyndale, C.M.G., M.D.

MEDICAL OFFICERS FOR THE ARMY: EXHAUSTION OF THE SUPPLY.

NOTIFICATION BY THE CENTRAL MEDICAL WAR COMMITTEE TO THE SECRETARY OF STATE FOR WAR.

The following letter has been addressed to the Secretary of State for War by the Central Medical War Committee. Copies have been sent to the Local Government Board and the National Insurance Commissioners:

CENTRAL MEDICAL WAR COMMITTEE.

Mr. T. JENNER VERRALL, LL.D., Bath, *Chairman.*

Members:

Sir Rickman Godlee, Bt., K.C.V.O., Ex-President Royal College of Surgeons of England.
Professor Harvey Littlejohn, Dean of the Faculty of Medicine, University of Edinburgh.
Sir William Osler, Bt., F.R.S., Oxford.
Dr. A. E. Shipley, F.R.S., Master of Christ's College, Cambridge.
Dr. T. W. Shore, Dean of the Medical School of St. Bartholomew's Hospital.
Sir Frederick Taylor, Bt., President Royal College of Physicians, London.
Sir T. Clifford Allbutt, K.C.B., F.R.S., Cambridge (President B.M.A.).
Mr. E. B. Turner, F.R.C.S., London (Chairman of Representative Meetings, B.M.A.).
Dr. J. A. Macdonald, LL.D., Taunton (Chairman of Council, B.M.A.).
Dr. G. E. Haslip, London (Treasurer, B.M.A.).
Lieut.-Colonel Sir James Barr, LL.D., Liverpool.
Dr. Mary Bell, London.
Lieut.-Colonel R. A. Bolam, Newcastle-on-Tyne.
Dr. H. W. Langley Browne, West Bromwich.
Dr. C. Buttar, London.
Dr. H. J. Campbell, Bradford.
Dr. H. J. Cardale, London.
Lieut.-Colonel J. Michell Clarke, Bristol.
Dr. Adam Fulton, Nottingham.
Dr. T. W. H. Garstang, Altrincham.
Major W. J. Greer, Newport, Mon.
Dr. Thomas Hennessy, Joint Honorary Secretary, Irish Medical War Committee.
Major Albert Lucas, Birmingham.
Dr. Arnold Lyndon, Hindhead.
Dr. D. Naunton Morgan, Bridgend.
Dr. Edwin Rayner, Stockport.
Dr. B. A. Richmond, Secretary, London Panel Committee.
Dr. H. J. Starling, Norwich.

429, Strand, London, W.C.2.,
August 3rd, 1917.

MY LORD,

We are instructed to inform you that the Central Medical War Committee, after a careful survey of the whole of England and Wales, is of opinion that no more medical men can be called upon to take commissions in the R.A.M.C. without seriously endangering the supply of doctors for the treatment of the civil community, and that further depletion can only be effected on the responsibility of the Government after carefully comparing the military with the civil needs. A few more appeals still remain to be heard before the last man considered available by the

Committee has entered the army, but from September onwards it will be quite impossible, under present powers and conditions, to satisfy the large demands of the Army Medical Department, which are now stated to be greatly increased.

In this connexion the Committee desires us to remind you of the letters sent to you on April 25th, April 27th, and June 2nd, 1917, and the suggestions made therein.

We have the honour to be,

My Lord,

Your most obedient servants,

(Signed) N. BISHOP HARMAN,

ALFRED COX,

Secretaries.

The Right Hon. the Earl of Derby,
War Office, Whitehall, S.W.

BRITISH PHARMACOPOEIA.

OMISSION OF PREPARATIONS.

The General Medical Council, acting in pursuance of the Medical Act, 1858, and the Medical Council Act, 1862, have withdrawn from the *British Pharmacopoeia*, 1914, the following medicines and compounds, which thereby cease to be included among the official preparations of the *British Pharmacopoeia* until further notice:

All *Confectiones*, except *Confectio Piperis*, *Confectio Rosae Gallicae*.
All *Glycerina*, except *Glycerinum*.
All *Misturæ*, except *Mistura Cretæ*, *Mistura Ferri Composita*, *Mistura Olei Ricini*.
All *Syrupi*, except *Syrupus*, *Syrupus Chloral*, *Syrupus Codeinæ*, *Phosphatis*, *Syrupus Ferri Iodidi*, *Syrupus Ferri Phosphatis cum Quinina et Strychnina*, *Syrupus Glucosi*.
All *Trochisci*, except *Trochiscus Krameriae* et *Cocainæ*, *Trochiscus Morphinae*, *Trochiscus Morphinae et Ipecacuanhae*.
Also
Caffeinae Citras Effervescens.
Decoctum Aloes Compositum.
Extractum Gossypii Radicis Corticis Liquidum.
Linimentum Potassii Iodidi cum Sapone.
Liquor Calcis Saccharatus.
Magnesii Sulphas Effervescens.
Mel Boracis.
Pulvis Amygdalæ Compositus.
Pulvis Glycyrrhizæ Compositus.
Pulvis Tragacanthæ Compositus.
Sodii Citro-Tartarus Effervescens.
Suppositoria Glycerini.
Tinctura Cardamomi Composita.
Tinctura Kino.
Tinctura Pruni Virginianæ.
Tinctura Rhei Composita.
Tinctura Sennæ Composita.
Unguentum Iodi.

EIGHTY-FIFTH ANNUAL MEETING

OF THE

British Medical Association.

LONDON, 1917.

ANNUAL REPRESENTATIVE MEETING.

Friday, July 27th (continued).

MR. E. B. TURNER, F.R.C.S. (Chairman of Representative Meetings); in the Chair.

A MINISTRY OF HEALTH.

On Friday, July 27th, the meeting resumed discussion on the question of a Ministry of Health, having before it the recommendations of Council under Medico-Political (SUPPLEMENT, May 5th, pp. 89-90).

In reporting the opening of the discussion on this subject an unfortunate error occurred, by which a large part of the speech in which Dr. Garstang, Chairman of the Medico-Political Committee, moved the resolution, eventually carried, in favour of the establishment of a Ministry of Health, was attributed to Dr. Macdonald. All the remarks set down to Dr. Macdonald on page 30 should have been assigned to Dr. Garstang, whose speech had great influence with the meeting.

Dr. R. A. LUNDIE (Edinburgh) now moved:

That, while welcoming the appointment of a Ministry of Health, this meeting is of opinion that the scheme for giving effect to this requires very careful consideration, and is strongly of opinion that the circumstances under which the profession is at present placed make it impossible effectively to consider any scheme before the end of the war, and it therefore cannot give its support at this time to the scheme proposed by the Council of the Association and very strongly protests against a provisional scheme having been forwarded by the Council of the Association to the Government on the plea of urgency.

He said that however desirable such a Ministry might be, the present time was the worst possible for such a radical change in the machinery of government, in view of the large number of men away on service who were prevented from expressing an opinion.

Dr. W. McE. CLENDINEN (Mid-Staffordshire) thought that the Council was being rushed to formulate a scheme. Matters had been pushed forward by the Government, and although it was probably necessary for the Council to consider the question, a bolder front might have been shown against impetuous proposals.

Dr. R. C. BUST (Dundee) pointed out that in 1903, in obedience to a resolution, the Council actually drafted a bill for the reorganization of the Local Government Board. If this general question of the co-ordination of the central medical service was one upon which they had been steadily working for about fifteen years, why should they refuse the opportunity of realizing their object when they had a chance?

Dr. J. A. MACDONALD said that it was in 1868 that the matter was first mooted by the Association.

Dr. C. E. S. FLEMING (Salisbury, Swindon, and Trowbridge) said that they had been told in that meeting that all the Council or the Association ought to do in the absence of their colleagues at the front was to adopt a defensive attitude and prevent anything being done which would not be agreeable to them, but surely the best means of preventing what one did not want was to construct what one did want. Either they had to accept—and allow to be accepted for those away—a scheme evolved by a lay body, or to endeavour to get accepted as far as possible a scheme which had been approved by the men whom those who were absent had trusted to look after the interests of their profession.

Mr. BISHOP HARMAN (Marylebone) said that a rider which appeared in the name of his Division seemed preferable to the Edinburgh amendment. That rider was adopted unanimously by Marylebone, which recognized that, while it would be impossible at such a great meeting as they were having that day to discuss adequately the details of a scheme, they could make certain general suggestions, and the Council would have sufficient information as to the trend of feeling to enable it to go on with the work it had begun. There was never such a time to get reforms of all sorts as a time of war. He regretted exceedingly that Lord Rhondda had gone from the Local

Government Board, for he seemed to have very clear ideas on the subject.

Dr. JOHNSON SMYTH (Bournemouth) said that the Government and the socialistic element behind it was not likely to wait. He hoped that Edinburgh would not press the matter.

Dr. JOHN STEVENS (Edinburgh and Leith) said that the Edinburgh amendment was the result of careful and repeated discussion by the profession in the Edinburgh Branch. It was passed in the Edinburgh Branch Council, in the Edinburgh annual meeting, in the Lothians Division, in the Edinburgh and Leith Division, and (in a somewhat restricted form) in the South-Eastern Counties (of Scotland) Division. Finally, the previous week a meeting of the whole profession in Edinburgh was held, and a similar resolution passed. It did not seem desirable for the profession even to commit themselves as to the formation of a Ministry of Health until some indication was given of what the proposals of the Government were to be.

Dr. J. P. CARTWRIGHT (Shropshire and Mid-Wales) said that he had been instructed to move an amendment similar to that of Edinburgh, save for the omission of all the words after "the end of the war."

The Edinburgh amendment was then put to the meeting and lost, and similar amendments by South Staffordshire and Southport consequently fell to the ground.

Dr. EVAN JONES (City) then moved:

That a small Committee, representative of the whole profession, be elected to consider the question of the establishment of a Health Ministry, and to draw up a comprehensive scheme, including every branch of medical science, for submission to the Prime Minister. That every effort should be made to postpone the establishment of a Health Ministry until this Committee has reported.

He said that as an emergency scheme the recommendations of the Council were commendable. But this was an enormous proposition, touching medical work in every aspect. Section 13 of the recommendations clearly showed that some kind of State service was contemplated even in the scheme of the Council itself. Did not that section foreshadow some great departure from medical practice as they had it now? Much greater elaboration of the scheme was necessary. It was suggested even at this stage that laymen should form a bare majority of the local administrative health committee. But if they once departed from the fundamental position that all the treatment centres should be under medical control, and admitted lay control, they were selling the pass. The cardinal principle of control of medical treatment by the medical profession must be safeguarded. The laymen must have their committees and demand what they wanted done, but the professional committees should be regarded not as their servants, but as contractors on a fair and square basis. That was not brought out in the Council's scheme to the satisfaction of the City Division. The Council had done well, but he hoped it would give them a little further lead.

Dr. GARSTANG, Chairman of the Medico-Political Committee, said that no single section of the scheme should be pulled out of its context and given an entirely imaginary value, as had been done in the case of Section 13 by Dr. Evan Jones. This section was entirely dependent upon the previous acceptance of the first twelve sections. And the essence of Section 13 was to safeguard the position of the general practitioner. He was entirely in sympathy with the principle that medical affairs should be governed by the profession, but it must be remembered that in all schemes it was the lay element, whether the Government or the county authorities, which found the money, and as long as the lay people found the money the profession would not realize its utopian dream, however much they all—and he included himself—wished it might be realized.

Major D. F. TODD (Sunderland) thought it a good thing that the Government and the general community had a say in these matters. On the general question, he said that defence was good, but attack was much better, and they were now in a position to attack. The one false step made by the Committee which had done this work, and done it remarkably well, was that they did not issue a short preface explaining why they acted as they did. If they had done so, there would not have been a word of dissent, but a vote of thanks at every meeting.

Dr. J. WISHART KERR (Glasgow Eastern) said that it looked very well on paper to speak of a small committee, but no small committee could carry out the vast amount

of work to be done under any such proposal. And where were they to get such a committee at the present time? The Council was the right body to do the work.

Major R. WALLACE HENRY (Leicester and Rutland) agreed that it was desirable that the matter should be threshed out in detail by the Council or another committee. The profession, however, ought to have another opportunity of considering it before it was submitted to the Government as a scheme.

General Approval of Scheme.

Mr. BISHOP HARMAN objected to the proposal of the City. The small committee was to be "representative of the whole profession." But could they bring in the malcontents? Could they agree on specific details? The resolution of Marylebone, on the other hand, did not commit them to any detail, nor prevent any resolution being sent up to the Council to be considered in relation to the broad lines of the scheme. It asked for general approval. The wording of the resolution was that of his colleague, Dr. Hawthorne, and showed his usual facility in framing reasoned propositions. Accordingly he moved:

That the Representative Meeting approves generally the scheme submitted for the establishment of a Ministry of Health, and leaves to the Council the duty of representing the scheme to the Government and of securing its acceptance so far as this is found to be possible.

This was taken as an amendment to the City motion.

Dr. MACDONALD pointed out that if they adopted the recommendation of the Marylebone Division they would be putting the matter into the hands of the Council. Let them not blame the Council afterwards if the Council had not exactly carried out the scheme.

Captain FOTHERGILL said that he hoped they would give due consideration before they adopted Mr. Bishop Harman's proposal. Had they their constituents behind them in adopting this policy?

Dr. E. J. DOMVILLE (Exeter) asked the meeting to give the Council a good lead. They should instruct the Council to consider the whole scheme, including amendments suggested by that meeting, and any further suggestions that might be sent in by the Divisions. There was no time to be lost. Legislation was being carried out by piecemeal departmental orders, and if they did not look out the whole details of the scheme would be arranged for them by the Local Government Board officials. Never before in the history of the Association, so far as he knew it, had they been so willingly listened to by the heads of the Government in matters of public health. As Chairman of the Public Health Committee, he had consented to the whole thing being taken out of his hands, and it had been referred to the strongest committee of Council they ever had. He moved an amendment to the Marylebone resolution, inserting an instruction to the Council to consider amendments presented to that meeting or by any of the Divisions, and this was accepted by Mr. Bishop Harman.

Dr. W. J. YOUNG (Cambridge and Huntingdon) supported the Marylebone amendment.

Dr. G. E. HASLIP (Westminster) thought that if they confined themselves to the first six clauses of the recommendation they would be perfectly safe. These dealt with central organization. But when they came to local organization it was a different matter. It appeared to him that they must go more deeply and fundamentally into the whole matter. Not a word was said about the housing question, and yet how vital that was to the health of the nation. As to the hospitals, were they going to throw over the voluntary system and have State hospitals? He thought that the main question was evaded in this scheme—touched upon, but not boldly dealt with. He asked the meeting to confine itself to giving approval up to clause No. 6, and after that the matter could be thoroughly gone into again.

Dr. H. B. BRACKENBURY said that Mr. Bishop Harman's amendment asked them to affirm the general principles which had been enunciated in the scheme, and the scheme did little more than enunciate them. If they were going into details they would find themselves hopelessly confused at that meeting.

The Marylebone amendment was then put to the meeting and carried, and thus became the substantive motion.

Dr. J. STEVENS asked if this meant that the Council would elaborate the scheme and present it to the Government without the profession having any further opportunity of considering it.

The CHAIRMAN explained that if the Council thought it necessary a Special Representative Meeting would be called.

Dr. HASLIP moved an amendment embodying the proposal he had just made in his remarks:

That only Clauses 1 to 6 of the scheme concerning a Ministry of Health be approved.

Dr. Haslip's amendment was lost.

Major WALLACE HENRY (Leicester and Rutland) moved an amendment which left to the Council, after submission to the Divisions, the duty of presenting the scheme to the Government so as to secure its acceptance as far as this was found possible. Unless the profession through the Divisions were consulted, the loyalty of some in the country was going to be shaken still further, and among these some who were fighting hard for the Association.

The CHAIRMAN asked in what way the mover of this amendment proposed to submit the scheme to the Divisions, and was informed that it could be submitted by letter with a request for reply.

Dr. MACDONALD asked the Representatives again to be clear as to what they were doing. This matter had gone through the regular course by which anything was placed before the Divisions. It was published in the SUPPLEMENT of May 5th—that was more than two months ago. Then he wished them to heed a newspaper extract which he read: "Mr. Bonar Law informed Mr. Charles Roberts that it was not intended to introduce the Ministry of Health Bill before the adjournment." Evidently, then, the bill was already drafted, and therefore the profession must decide quickly. If the Divisions had not taken the opportunity of studying the proposals laid before them, that was not the fault of the Council.

Dr. R. C. BUIST asked Dr. Macdonald whether, as an experienced parliamentarian on behalf of the profession, he could give them any idea as to whether a Ministry of Health Bill would be likely to cover more than the general policy of the first six propositions which they had been debating or would enter into matters of local arrangement.

Dr. MACDONALD said that those who remembered the introduction of the Insurance Act would bear in mind that there were a certain number of principles enunciated in the Act and a great deal of the working was left to regulations, which, of course, had the force of law. It might well be the same in this instance.

Dr. JENNER VERRALL pointed out that if Major Wallace Henry's amendment were accepted it left unsettled the point as to whether the meeting did or did not approve generally of this scheme. Any expression of opinion from that meeting would be dropped out.

Dr. D. A. SHEAHAN (Portsmouth) said that the Ministry of Health meant one of two things—either that they (the practitioners) freed themselves and gained the liberty they lost under the Insurance Act regulations, or that they perpetually locked the fetters upon themselves which had been placed upon them in the first instance through having medical matters discussed and arranged by local insurance committees. The mind of the governing body was at the present time in a fluid condition, and therefore now was the moment for them, if they meant to do anything, to try and secure such part as they could in the government of medical affairs by medical men. A frequent objection urged against the idea that medical authority should dominate medical contract work was that the taxpayer ought to have something to say in the matter. But what had the taxpayer to say concerning the army and navy save through the respective ministries? The Ministry of Health would furnish the same connecting link in this instance. He supported the view that the scheme, after being discussed by the Council, should be referred to the constituencies generally.

The amendment was lost, and the Marylebone amendment was carried as the substantive motion as follows:

That the Representative Meeting approves generally the scheme submitted for the establishment of a Ministry of Health, and instructs the Council to consider the amendments presented to the Representative Meeting, or by any Divisions, to present the scheme to the Government, and to secure its acceptance so far as it is found to be possible.

CONFIDENCE IN THE ASSOCIATION.

Dr. EVAN JONES (City) moved, without a speech, an amendment standing in the name of his Division:

That this Division and many other members are fast losing what confidence they had in the governing body of the

Association owing to their neglect of the interests of the profession, and as evidence we know of many cases of members who have resigned for this reason, and of many others who are contemplating a similar step.

Dr. MACDONALD protested warmly against such a motion as this being brought forward formally. If a Division thought it right to formulate such an amendment, their Representative ought to justify it. Men who had been working their hardest in the Association's interests found it difficult to speak without anger of such a proceeding. (Hear, hear.)

Major RUSSELL COOMBE, in reply to Mr. Bishop Harman, said that since the recent propaganda was instituted there had been 687 definite applications for membership.

Dr. C. O. HAWTHORNE (Marylebone) hoped that on this matter a word would be allowed, not only to an official representative of the Council, but to an ordinary private member like himself. He was not in the least disposed to blame the City Division for arraigning the Council, but there was a word to be said in reference to the form in which this amendment was presented. In the first place, they were told that the City Division spoke not only for itself but for other members outside. By what constitutional authority did it do so? Then, again, it could not be congratulated on its editorial skill. The amendment began loftily in the third person, and before it finished it declined to the sweet simplicity of the first. Apart altogether from the question rightly raised by the Chairman of Council, the form as well as the substance of the amendment reflected no credit upon the City Division. When the Division next embarked upon enterprises of this kind he hoped it would bear in mind that ignorant outsiders might possibly judge the Association as a whole from one of its Divisions, and therefore he hoped that those who drew up such amendments in the future would have some respect for the primitive delicacies of the English tongue, and, moreover, that they would express their sentiments, whatever they might be, in terms capable of being understood by the average person.

Dr. EVAN JONES said that the amendment was moved and seconded by two of the oldest and most respected members of the City Division. He apologized for not having spoken when moving it, but he was unprepared for it being called on, believing that an amendment in similar terms which came later superseded it.

On a show of hands the amendment received practically no support.

MATERNITY AND CHILD WELFARE.

Dr. C. W. CENNINGTON (Hampstead) moved two riders standing in the name of his Division, one of them urging that a medical practitioner engaged by any organizations concerned in social work, such as maternity and child welfare, should not be in active practice in the district; and the other that where public funds were placed at the discretion of such an organization, the majority of the administrative body should consist of the representatives of the borough councils concerned.

Dr. H. B. BRACKENBURY said that the intention of the first rider seemed to be that when the general practitioner was made the salaried officer of a maternity centre it was better that he should be brought in from outside than that he should be picked out by a lay body from the practitioners of the district. If this was carried, it meant that local practitioners of a particular neighbourhood would have no opportunity of doing this work if they desired it. He thought that such an opportunity should not be ruled out.

The first rider was lost and the second was withdrawn, the mover stating that he was content that the matter should be left to the Council.

WAR PENSIONS COMMITTEES.

Dr. W. E. THOMAS, on behalf of North Carnarvon and Anglesey, moved:

That the fees for the examination of and report upon discharged soldiers for the local War Pensions Committees be provisionally fixed at 5s. in accordance with the opinion of the Council as expressed in para. 78 of report (SUPPLEMENT, May 5th, p. 90); but that this meeting does not consider such a fee, as a permanent arrangement, adequate remuneration for the information required.

Dr. C. E. S. FLEMING (Salisbury, Swindon, and Trowbridge) said that an attempt was being made by the county disablement committees through the statutory

committee to restrict to certain medical men in the district the right to issue these reports. That was a very dangerous principle. At a meeting of medical men in Wiltshire it was agreed that any medical man who was considered fit to take charge of a disabled soldier was also fit to issue a report on him; and not only so, but he was the best person to do it. There might be cases where a medical man did not feel himself competent to issue such a report, hence special referees should be appointed. With regard to the fees, they did not see why a second certificate should be given at a lower fee than a first, since a second certificate generally indicated a difficult case; where a referee was required the fee should be at least a guinea. After these matters were discussed they were brought before the War Pensions Committee, which showed at first some unwillingness, but when the Committee was informed that the British Medical Association had decided that the fee for examination should be provisionally fixed at 5s., the chairman of the meeting said that in that case they had no alternative but to accept it, which was something of a tribute to the Association.

The rider was carried.

SUPPLY OF PETROL AND REPAIR OF MOTOR CARS.

Dr. A. O. HOLBECH (Worcester) moved that a strongly worded representation be sent to the proper authorities and the Petrol Department that the present facilities granted to the medical profession were not sufficient.

Dr. CRAWFORD TREASURE mentioned the great difficulty of getting attention to repairs—a serious matter in many districts where medical men were absolutely dependent upon their cars.

The CHAIRMAN said that the Ministry of Munitions would have to be approached with regard to repairs. He suggested that in the covering letter from the office it should be insisted that the diminished number of medical men now left in practice must have every facility for getting about.

The rider was adopted.

MEDICAL FEES.

Dr. EVAN JONES brought forward an amendment by the City Division expressing disappointment that the Council had done nothing to make the public realize the justice of the increase of all medical fees owing to the increased cost of war time.

Dr. BUIST moved that they proceed to the next business, which was agreed to.

On the motion of Dr. H. J. ROBINSON (Burnley), it was agreed to enter a protest against the mean action of the Government in reducing the fee for the notification of infectious diseases from 2s. 6d. to 1s.

MEDICAL CERTIFICATES FOR MUNITION WORKERS.

Dr. G. H. LODGE moved a rider on behalf of the Sheffield Division, that when a medical certificate was required by the Ministry of Munitions the form should be issued by the firm requiring it, and should bear their stamp and date, and that the fee charged by the doctor should be not less than 2s. 6d.

The CHAIRMAN pointing out that the Ministry of Munitions had issued these certificates, Dr. LODGE explained that the form of the certificate was approved; the intention of the rider was to insist that the certificate should bear the firm's stamp.

Dr. G. H. LOWE (Cleveland) said that in his district these certificates were largely ignored. The doctors had given their own.

The rider was lost.

THE METRIC SYSTEM IN PRESCRIBING AND DISPENSING.

A rider was moved on behalf of Belfast, advocating the general use of the metric system in dispensing, prescribing, and treatment.

Dr. R. C. BUIST (Dundee) said that the Association issued a special report in 1911 and secured the sanction of the Representative Meeting (see SUPPLEMENT, April 29th, 1911).

Mr. BISHOP HARMAN (Marylebone) suggested that it would be a better course to recommend to colleges and universities that lecturers should teach their students in this fashion.

Dr. E. O. PRICE (North Carnarvon and Anglesey) thought that it would be a disgrace to them as a body of scientific men if they did not adopt a resolution of this

sort. They were not legislating, but simply recommending.

Dr. C. O. HAWTHORNE (Maylebone) said that the metric system had been pushed upon the attention of the General Medical Council to such an extent that they now had it partially recognized in the *Pharmacopoeia*, where the terms of dosage were set out in the metric as well as in the imperial notation, and therefore it was possible for the student at least to familiarize himself with it.

On the amendment of Mr. BISHOP HARMAN, accepted by the Belfast representative, the rider was narrowed down to expressing the opinion that "the general use of the metric system in the teaching of dispensing, prescribing, and treatment would be beneficial to the scientific interests of the medical profession," and in this form was carried.

PROPOSED ANNUAL HANDBOOK.

Dr. C. J. PALMER (Nottingham) moved:

That the Council publish an annual handbook giving decisions of Council and of the Representative Body on subjects of medico-political importance, and such other matters as may be thought desirable.

He said that such a manual would do something to dissipate the ignorance which prevailed in some quarters as to what the Association did. It would at least bring the matter succinctly before members and prospective members. He did not believe that the issue would be a charge upon the Association, for, published at a shilling or even half a crown, it would command a profitable sale.

Dr. GARSTANG said that at the last Council meeting a resolution to this effect from the Medico-Political Committee was considered and in principle accepted, and the details were referred to the next meeting of the Organization Committee. The somewhat large and imposing handbook which they had had ten or eleven years ago was not likely to be revived, and he did not want his answer to be interpreted more favourably than the occasion warranted, but the matter would receive the greatest possible consideration as soon as the new session began.

The rider was agreed to.

COMPENSATION ACTIONS.

Dr. CRAWFORD TREASURE (Cardiff) moved:

That the Association press on the Government the necessity that in all compensation actions in the county courts the presiding judge should be required to have the assistance of one or more medical assessors to sit with him, to guide him on technical medical details, in the same manner as a stipendiary magistrate is assisted by nautical assessors when conducting a wreck inquiry.

Major D. F. TODD (Sunderland) said that in the Workmen's Compensation Act the whole machinery was laid down for the employment of a medical assessor. The weak point was that the employment of such assessor was left to the judge's discretion.

Dr. SELLERS said that it was open to both sides to ask for the assessor.

Dr. TREASURE said that the rider covered the specific point mentioned by Major Todd.

The rider was carried.

CERTIFYING SURGEONS UNDER THE FACTORY ACTS.

Dr. W. F. DEARDEN (Manchester) moved on his own initiative, and not from his Division:

That it be an instruction to the Council to take any action it may deem necessary in any legislative attempt which may be made to transfer any of the duties of certifying surgeons under the Factory Act to school medical officers.

The motion was seconded by Dr. J. D'EWART.

Major D. F. TODD urged that this matter should not be brought forward now. It was one of the things which would come up under the Ministry of Health.

Dr. H. B. BRACKENBURY said that this was not a question as between the school medical officer and the factory certifying surgeon. Nobody could transfer their functions, short of Parliament transferring the functions of the Home Office to the Education Department. But it had been mooted that the education officer should examine young persons employed in factories. The Council in drawing up its scheme for a Ministry of Health could bear such points in mind.

Dr. DEARDEN said that all he wanted was that the Council should be in a position to act if anything of the kind suggested in the motion should materialize.

The motion was lost, and the remainder of the reports were approved.

Dr. GARSTANG expressed his thanks to the Representative Body for the courtesy they had shown him while he had been bringing forward a great deal of contentious matter.

ORGANIZATION.

Major RUSSELL COOMBE, as Chairman of the Organization Committee, moved the Council's recommendations with regard to deputy Representatives, membership of Organization Committee, representation of certain committees on others, and grouping of Branches for election of Council, as given in the SUPPLEMENT, May 5th, pp. 83-84, paras. 31-37, and July 7th, p. 3, para. 171, and these were approved.

Dr. EVAN JONES (City) moved an amendment urging that a committee of investigation, unconnected with the working of the Association, should be appointed to inquire into its working, and for this purpose to be empowered to employ the services of a trained business expert. He said that a certain amount of dissatisfaction existed, possibly over small matters.

A motion to proceed to the next business was carried, and the whole of the reports under "Organization" were approved.

THE JOURNAL.

Major ALBERT LUCAS, Chairman of the Journal Committee, moved that the Annual Report of Council under that heading be approved. He said that the difficulties in the publication of the JOURNAL in war time were necessarily very great. Pages had been curtailed, and the price of paper had risen enormously. The addition of a penny to the cost of the production of each JOURNAL meant an increase in the Association's expenditure of £5,000 a year. Thanks to the Financial Secretary, the income from advertisements had kept up very well. He had no doubt the new Assistant Editor would prove a most efficient officer of the Association. Both the Editor and Assistant Editor were paid an inclusive salary which covered their contributions.

Major D. F. TODD (Sunderland) said that he was pleased that this question of editorial contributions had been settled in a businesslike way, but he noticed some members of the staff still received payments for contributions. In his view there should be no such extra payments to whole-time officers.

Dr. HAWTHORNE asked whether reference was permitted to the subcommittee charged with the inquiry into the suitability of the contents of the JOURNAL.

Major LUCAS said that at the meeting of the Journal Committee on April 4th a subcommittee was appointed to consider the whole question of the suitability of contents of the JOURNAL and SUPPLEMENT to the present needs of the Association. The subcommittee had met and reported, but the Journal Committee had not yet had an opportunity of receiving and considering the report. In reply to Major Todd's remark, the rule as to an inclusive salary now obtained both with regard to the Editor and Assistant Editor. As to the Sub-editor the matter was on a rather different footing owing to a pre-existing arrangement, but should they at any time appoint a new Sub-editor they would doubtless be able to arrange for an inclusive salary. The small payments made to other members of the staff were for work done outside office hours.

Dr. HAWTHORNE said that there was some feeling that the contents of the JOURNAL, while meriting high eulogies from many points of view, might be improved by the inclusion of a greater number of papers of distinct clinical interest to men engaged in civil practice.

Dr. W. H. I. SELLERS (Preston) moved that the SUPPLEMENT be issued only to members of the Association. Many matters were discussed in their own meetings long before they were ready to be given broadcast to the public.

Major LUCAS said that not everything was published in the SUPPLEMENT. Matters were not disclosed therein which could be used against them by the other side. Even if the SUPPLEMENT were restricted to members, some 20,000 copies would be published, and outside bodies would generally find it easy to obtain a copy from some member of the Association. To publish an issue without the SUPPLEMENT would also involve technical difficulties in connexion with printing and publication.

Dr. C. H. PANTING (South-West Essex) said that it was annoying to have the SUPPLEMENT waved in one's face in insurance committees. So long as the public could possess themselves of copies in the ordinary way it was no good protesting against the use of information by outside bodies.

Dr. Sellers's rider was lost. A further rider, that the price of the JOURNAL to non-members should be 1s., was withdrawn, and the Report of Council under this heading was approved.

SCIENCE COMMITTEE.

The Annual and Supplementary Reports of Council under the heading "Science" (SUPPLEMENT, May 5th, p. 85, and July 7th, p. 4) were approved, on the motion of the CHAIRMAN.

OVERSEAS BRANCHES.

On the motion of Dr. J. A. MACDONALD, the Annual Report under the heading "Overseas Branches" (SUPPLEMENT, May 5th, p. 99) was approved.

MEDICAL ETHICS.

Position of Medical Referee in relation to Medical Attendant.

Dr. M. G. BIGGS, Chairman of the Central Ethical Committee, moved the approval of the memorandum on the question of whether a medical referee or inspector should inform the medical attendant of any modification in the treatment of a case which he found it necessary to recommend to his employer (SUPPLEMENT, May 5th, Appendix i, p. 100). This was agreed to without discussion.

Dr. Biggs then moved the addition of the following rule to those already approved by the Representative Body in respect of the position of medical practitioners called upon to examine (otherwise than by request of the patient or persons acting on his behalf) patients under the care of other practitioners:

If the medical inspector finds it necessary to report to his employer that any modification in the treatment which is being carried out is in his opinion necessary to the more rapid recovery of the case, he shall so inform the medical attendant.

The CHAIRMAN explained that the Representative Body had already decided that the medical inspector might make such an examination and report upon it, but this did not say that he was to report to the medical adviser.

Dr. J. STEVENS moved an amendment to delete the words "it necessary to report to his employer."

Major A. LUCAS seconded. He said that they examined patients for different bodies, companies, corporations, and all kinds of people, many third party cases and the like, and the effect of the rule as it stood would be to put them on the same terms as a workman. The omission of three or four words would get over the difficulty.

Dr. MACDONALD supposed a case in which a person had an interest in the recovery of the patient at the earliest possible time; had not that person a right to demand from the medical inspector a report which included any suggestion he might think fit to make with regard to future treatment?

The SOLICITOR said, in reply, that that person was entitled under the law to such advice on that matter as the medical inspector could give, and if the medical inspector felt that the circumstances were such as were not contributing to the recovery of that patient, he was entitled to say so.

Major D. F. TOMB (Sunderland) pointed out that an indiscreet medical inspector might raise a number of points with regard to treatment which would have the effect of casting the whole affair into a hopeless muddle. The common-sense of the matter would be for the inspector to communicate with the medical attendant and, if necessary, suggest other lines of treatment.

The SOLICITOR said that Major Todd had put it that the medical inspector should make suggestions as to the form of treatment he considered right. Supposing these suggestions were ignored and not followed? Surely the inspector must see that they were carried out?

Major TOMB thought that the legal adviser was raising a fresh issue.

Dr. BIGGS said that the rule had been brought forward largely as a result of the advice given by the Solicitor, which he had repeated there that day. If the words with regard to the employer were left out, as proposed by Dr.

Stevens, the specific part of the rule was taken away and the whole thing spoilt.

Dr. STEVENS's amendment was lost.

Major G. PARKER (Bristol) failed to understand Major Todd's contention that the inspector should not report to the employer on the subject of treatment. How could he, in a given case, disagree with the diagnosis without saying also that he disagreed with the treatment? The business of the referee was to give a perfectly honest report upon the facts, including both treatment and diagnosis.

Sir CLIFFORD ALLBUTT suggested that the following words be added to the rule: "If possible in the first instance" after the word "shall." This would save a good deal of friction and annoyance. He moved the insertion of these words.

Dr. C. E. S. FLEMMING (Salisbury, etc.) seconded, and pointed out that the medical inspector in his report had to say how long it would be before the man was fit to work; could he do so unless he knew what sort of treatment the man was having, and without making suggestions as to different treatment if necessary?

Dr. C. E. ROBERTSON (Glasgow Southern) said that he would like to ask what was the exact position of the referee. Were they bound as a profession to accept the referee's opinion?

Dr. MACDONALD thought it should be made clear that by "the employer" was meant the employer of the medical inspector, not of the patient.

Dr. W. E. THOMAS (North Glamorgan) asked whether the medical inspector had the right to divulge the facts of the case to the indemnity society.

The SOLICITOR asked whether Dr. Thomas's suggestion was that such an act on the part of the medical referee or inspector in communicating to the indemnity society amounted to libel, and on Dr. Thomas saying that that was his suggestion, the Solicitor said that his answer would negative that, and he would be prepared to defend it.

The new rule was adopted, with the addition of the words suggested by Sir Clifford Allbutt.

Two amendments by Liverpool to paras. 58 and 59 of the report (SUPPLEMENT, May 5th, pp. 85 and 86) were negatived. The first, which thanked the General Medical Council for refusing to assist the British Medical Association in getting members struck off before proof of fault, was described by Dr. BIGGS as amounting to a vote of censure; the second was an objection to the wording of the paragraph.

Practitioners Examining Patients under Care of other Practitioners.

Appendix II (position of practitioners examining patients under care of other practitioners), of SUPPLEMENT, May 5th, p. 100, was the subject of a series of resolutions moved by Dr. A. O. HOLBECH (Worcester). The first, which was accepted by Dr. Biggs and carried, referred it to the Council to consider whether the word "examination" should be substituted for the word "visit" in Rule (i). The second related to the desirability of adding to Rule (iv) that "bandages, dressings, or appliances shall not be removed without the consent of the medical attendant." Mr. BISHOP HARMAN pointed out that this would place an absolute embargo upon a large proportion of examinations. Dr. HOLBECH said that the object he had in view was to afford the medical attendant every opportunity to be present on these occasions.

Dr. F. L. POEHN (Oldham) said that in every case of this kind with which he had had to do the medical attendant of the patient was notified as to the hour and day of his visit, but in not two per cent. of his cases did the medical attendant turn up. He thought the situation was quite sufficiently safeguarded without the amendment.

The motion was lost, but another motion by Dr. HOLBECH with regard to Rule (v), suggesting the alternative opening words "That when the medical attendant fails to answer a communication made to him by the medical inspector," was accepted as a reference to the Council.

Major G. PARKER (Bristol) moved an amendment, which was seconded, referring it to the Council to consider whether the rules in Appendix II should be held to include hospital as well as private patients.

Major LUCAS said that the passing of these last resolutions did not necessarily commit the Central Ethical

Committee or the Council, but they embodied principles of very serious import to large numbers of medical men—especially the alteration suggested for Rule (i)—and if they were carried out in regulations these men could not and would not remain members of the Association. The effect of the alterations proposed by Worcester would be to make the position in an industrial area, where there were hundreds of cases to be seen, absurd and impossible.

Major Parker's amendment was lost, and the whole of the reports of the Council under "Medical Ethics" were approved.

NATIONAL HEALTH INSURANCE.

CONSTITUTION OF INSURANCE ACTS COMMITTEE.

Dr. H. B. BRACKENBURY, Chairman of the Insurance Acts Committee, moved the adoption of the amended schedule as to the constitution of the Committee (SUPPLEMENT, May 5th, p. 92). He said that if it had not been that a contrary amendment stood on the paper he would have thought that this would be considered entirely a formal matter, and passed without discussion. The question at issue was whether it was desirable that the Committee should contain a proportion of men who were not working under the Insurance Acts. He had been in various parts of the country urging it as one of the virtues of the Insurance Acts Committee that it did not consist wholly of men working the Insurance Act. The functions of the Committee were important and manifold, and they were, broadly, to deal with all matters arising in connexion with the National Insurance Acts, not merely the relationship between the insurance practitioners and those Acts, and it was of vast importance in view of various eventualities that there should be upon the Committee a certain number of members who were not in insurance practice. The proposed alteration in the constitution of the Committee was that instead of six direct representatives of Local Medical and Panel Committees there should be fifteen. That was done on the recommendation of the Conference of representatives of those committees held last October.

Dr. E. A. STARLING (Tunbridge Wells) formally moved that, with the exception of the *ex officio* members of the Association, the Committee should consist of panel practitioners only. The amendment was lost, and the original motion agreed to.

The CHAIRMAN pointed out that it was very important that the Insurance Acts Committee in as entire a form as possible should continue in office until the next Conference of Local Medical and Panel Committees, and on his motion it was agreed to authorize the continuance in office until the next conference of those members of the Committee who were elected for 1916-17 on the nomination of Local Medical and Panel Committees.

STATE MEDICAL SERVICE.

Dr. M. G. BIGGS (Chairman of the Non-Panel Committee) moved on behalf of the Council the recommendations with regard to medical attendance and treatment of industrial and poorer classes (SUPPLEMENT, July 7th, p. 7, para. 204). As to the first of these, that such medical treatment should not be carried out by a whole-time salaried State medical service,

Captain FOTHERGILL asked what was the urgency of this question. The question of the improvement of the Insurance Act or the general future of National Insurance was being considered by the Insurance Acts Committee, who had already prepared a report. When that matter had been before the Divisions again, the Insurance Acts Committee would meet further and consider the whole question. Was there any urgent reason why the situation should be anticipated by this resolution?

Dr. R. C. BRIST (Dundee) said that his Division had not instructed him to support a salaried State service, but they were very strongly of opinion that to adopt a simple negative motion of this kind at the present time would be leading the Association into danger of another disaster. It was common knowledge that from one side or another the offer of a salaried State service was going to be made. They did not know what the strength of the outside demand for that was likely to be, but that the offer would be made seemed most probable, and they had to face it. A considerable number of members of the profession here and there had expressed themselves in favour of a salaried

State service. If the offer of the conditions were sufficiently attractive they would be faced with a very serious division of opinion in the profession, which the Association would not be able to hold in check, and the opinion of the Association and of the profession as a whole should be formed on much more intelligent grounds than any they had had up to the present time. His Division suggested that the Council should consider the matter of a State medical service, and let them know what they were proposing to favour or to refuse. He moved an amendment on those lines.

Major TODD suggested that this would open up the detail they had avoided that morning in discussing the Ministry of Health.

The amendment was lost, and the original motion carried.

Dr. BIGGS moved the second of the recommendations, which was agreed to after being amended to read that the medical treatment of these classes should be carried out by a "modified and (instead of or) improved insurance scheme." To the third of these recommendations,

INSURED PERSONS AS PRIVATE PATIENTS,

Dr. JOHN STEVENS (Edinburgh and Leith) moved an amendment:

That every insured person shall have the right to be attended as a private patient by any registered medical practitioner willing to attend, without the necessity of any form of contract on the part of the practitioner, and without the loss to the insured of any of the benefits of the National Insurance Act; and that the British Medical Association be requested to incorporate this provision in their proposed amendments to the Act.

He said that this was not brought forward in any spirit of antagonism to the principle of National Insurance, and still less to those who had joined the panel. About two-thirds of the insured persons were previously not attended under contract conditions, but in the main as private patients, and he claimed that the Association ought to adopt the policy of demanding that there should be a restitution of the conditions under which these people were attended, so that they should have the right to be treated as private patients once more. If effect were given to his amendment, it would go a long way towards healing the present division in the Association over the Insurance Act, and that was the object, more than any other, with which he submitted it. The proposition could not hurt or threaten any one.

Captain E. R. FOTHERGILL said that there must be a contract of some sort. They could not imagine, unless they lived in Utopia, that any nation was going to allow doctors to attend persons who came under an Act and a certain amount of discipline without any contract whatever and yet receive payment.

Dr. I. W. JOHNSON (Bury) said that it was at the unanimous request of his Division that he opposed contracting out under the Insurance Act in every shape and form in which the matter might come before the meeting.

Dr. H. B. BRACKENBURY said that it was not a question of contracting out under the Insurance Act. What the amendment said was that doctors should be allowed to take State pay without being obliged to do anything for it. Could that proposition commend itself to any body of medical men?

Dr. D. A. SHEAHAN (Portsmouth) said that he did not understand the amendment in the sense in which Dr. Brackenbury had interpreted it. Many people were forced under the Insurance Act who wished to have a private doctor and pay him for work done. These people did not trust contract practice.

Major W. J. GREER (Monmouthshire) strongly opposed the amendment. The proposal had been brought up time after time at the Representative Meetings and ought to have been dead long ago.

Dr. STEVENS, in replying, brought forward some quotations from Mr. Lloyd George, one of them affirming that there was nothing in the Act which enforced contract practice anywhere. He cited the number of insured persons who had refused to put their names on the lists of panel doctors—about 20,000 in Edinburgh, out of a total of a little over 100,000 insured persons—as a proof that a considerable body of people demanded the restitution of their former rights.

The amendment was lost.

MEDICAL TREATMENT OF THE INDUSTRIAL AND POORER CLASSES.

Captain FOTHERGILL, speaking on the main proposition, objected to its drafting. Under the sweeping dictum of (a) ("complete and efficient medical and surgical treatment to that section of the community which is unable to provide such treatment for itself") seemed to be included a number of their private patients who at the present moment paid them fees up to 7s. 6d. and 10s. 6d. but were not able to pay the fees for large operations. He knew the Committee did not mean it—it was bad drafting—but the recommendation suggested that all that class of patients should be put in category (a). According to (b) ("freedom to any other person involved in any system of State medical service to make his own individual arrangements for treatment if he so desire") the industrial working classes were to have absolute freedom of choice for making their own arrangements in the Edinburgh style. Why this *volte face*?

Dr. BRIGGS said that what was present to the minds of the Non-Panel Committee was the abuse that had taken place in Wales, and they wanted to word their resolution so as to shut out any chance of that occurring. Captain Fothergill had set up a bogey. The class named under (a) were very poor persons indeed and could not possibly include people paying a half-guinea fee.

The motion was lost.

MEDICAL REFEREES.

Major TODD, in the absence of the Representative of Worcester, moved an amendment disapproving the scheme for the payment of 5s. fees to local referees appointed by approved societies (SUPPLEMENT, May 5th, p. 96, para. 125). In his own area they had stood out loyally for a fee of 10s. 6d., but some areas had broken away.

Dr. BRACKENBURY said that there had been no departure from the policy of the Association, but the actual resolution, while making the minimum fee 10s. 6d. for cases seen as individual cases, gave power to the Council to sanction a scheme sent up by any Division involving smaller fees where men had accepted appointments to approved societies if such sanction could be reasonably given. The Council had handed over the matter to the Insurance Acts Committee, and permission had been given in three cases, always, however, subject to the Committee being satisfied (1) that there was a real scheme in that area for dealing with the matter, (2) that there was a fairly unanimous opinion in the Division in its favour, (3) that there would be no difficulty in surrounding areas.

Dr. H. F. OLDHAM (Lancaster) said that with considerable trouble he had, as chairman of the Division, obtained the resignation of the appointments offered them of referee by men in his Division who had been acting for the 5s. fee. The one man who refused to be guided by the opinion of the Division was the only one who profited; the others, who had loyally fallen in with the chairman, had lost by it, and would be up in arms against the Association for leaving them in the lurch.

The CHAIRMAN suggested to Dr. Oldham that the gentlemen of whom he had spoken should abide by the decision of the Representative Body, and if any gentleman did not, the matter should be referred to the Ethical Committee. He added that the Representative Meeting took a very wise course in that it practically left the whole matter to the option of the Divisions.

A motion to proceed to the next business was carried.

Dr. G. E. HASLIP (Westminster) desired to ask the Chairman of the Insurance Acts Committee, not in any personal way, whether that committee was an advisory committee to the Commissioners or a fighting committee for the profession. He belonged to a Panel Committee in which this question was being constantly discussed.

Dr. BRACKENBURY maintained that it was a fighting committee, but before it fought it attempted to negotiate. He denied that its relative position towards a Government department was that of a subordinate advisory committee.

The whole of the report under "National Health Insurance" (SUPPLEMENT, May 5th, p. 92) was then approved.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

Dr. BRACKENBURY, in moving the approval of the Supplementary Report under the heading "National Insurance," spoke at length on the question of discharged disabled

soldiers and sailors. They had maintained that disabled men must necessarily require greater medical attendance than healthy persons, and that therefore special provision ought to be made for payment. They had negotiated with the Commissioners and with the Government generally, and eventually persuaded them that it was necessary to make special arrangements. They had not much difficulty in convincing the Commissioners, but the difficulty was much greater with the Treasury. Of course they had no positive proof of the truth of their case, though they considered it to be axiomatic; still less had they any means of gauging what would be a proper remuneration for the extra attendance. Being unable to make out a statistical case for an increased capitation grant with regard to these men, they were obliged to accept payment by attendance as an experiment until they had accumulated data which would enable them to determine the proper remuneration. The treatment of these men therefore, while it was not taken entirely outside the machinery of the Insurance Acts, was taken outside their monetary provisions. If the pool did not meet the bills sent in on an attendance basis, the Treasury would make up the pool to the amount required. The payment would be the same as for temporary residents. That was simple enough so far as men hereafter to be discharged were concerned, but with men already discharged the case was more difficult, because some were already on the list of an insurance practitioner. That practitioner would have the option as these men presented themselves to him of continuing attendance according to the old capitation arrangements or of transferring them to this new order. Statistics would be got out and reports made quarter by quarter during the next twelve months or so, and then it would be open to them to consider the whole matter. There had specially to be considered the class of persons who were coming out of the army and were not insured. There had been placed on the Statute Book this session Insurance Act No. 3, dealing with these men, and putting them in the same position as insured persons so far as this was concerned. The Committee made the arrangement that it should be open to any discharged disabled soldier or sailor to choose any doctor he liked, whether on the panel or not, who signified his willingness to treat him; and they went a step further, allowing all these men to have this freedom of choice, whether they were insured persons or not. As some of the men coming out of the army had considerable incomes, it was necessary that the same income basis—namely, £160 per annum—should be applied as to voluntary contributors.

Dr. J. R. RATCLIFFE (Birmingham Central) asked whether the Council took into consideration the question of the treatment of discharged soldiers suffering from tuberculosis.

Dr. BRACKENBURY replied that sanatorium benefit came under the same regulations.

Dr. J. W. BONE (Bedford) referred to hospitals which had been approached by War Pensions Committees to take discharged soldiers as out-patients at 6d. per attendance in ordinary cases, and 1s. 6d. in cases where the attendance included massage and electrical treatment, and as in-patients at 4s. a day.

Dr. R. A. LUNDIE (Edinburgh and Leith) moved:

That any provision made for medical attendance on discharged disabled soldiers and sailors ought to be outside the National Insurance Acts.

He said that this amendment was brought up in order to maintain what had been hitherto the official attitude of the Association, and had been lost sight of.

Dr. H. B. BRACKENBURY said that he was sure the Representative Body would not do anything so foolish as to pass an amendment of this kind. It was entirely futile. Parliament had said that these people were to be dealt with under the Insurance Act machinery. The Committee had succeeded, in spite of this, in getting them dealt with under a more liberal scheme than that laid down for the ordinary insured person. The Act was the law of the land. He trusted they would not develop into passive resisters.

Dr. J. STEVENS (Edinburgh and Leith) submitted that it could not be futile so long as the regulations were not out—the regulations were the important thing.

The amendment was lost, but the following rider, moved by Dr. LUNDIE, was adopted:

That this provision ought to be made under conditions which will allow of these persons being attended by any registered medical practitioner they may respectively choose.

Dr. JAMES PATTON (Consett and Gateshead) hoped the meeting would not approve the same payment as for temporary residents. He suggested that the fee should be 3s. per attendance, in view of the probable large number of heart and kidney cases and cases needing dressings, and moved a rider to that effect.

Dr. BRACKENBURY put it to the meeting that Dr. Patton's rider would scrap the bargain which after so much labour the Committee had arrived at on behalf of the profession.

The rider was lost.

FEDERATIONS OF MEDICAL AND PANEL COMMITTEES.

Dr. F. L. POCHIN (Oldham) moved:

That federations of Medical and Panel Committees formed locally for exchange of information, and the discussion of problems peculiar to the conditions of practice in their own areas with a view to securing concerted action thereupon, if necessary, through the British Medical Association, should be encouraged by the Insurance Acts Committee.

He said that the idea was to form the federation on strictly non-party lines. It would be in no way antagonistic to the British Medical Association, but would serve to keep touch between the various Panel Committees of the area. The aid of the Association would be called in when necessary, but the greater part of the business of the federations would not be important enough to warrant that intervention.

Dr. J. McCREA (Reading) suggested the adoption of the Reading plan by which they had arranged to hold the borough panel meeting, the county panel meeting, and the local Association meeting in a time relation to one another, and afterwards to hold a meeting of all the executive officers of the three bodies.

Dr. BRACKENBURY said that the opinion of the Insurance Acts Committee was against the formation of such federations. They felt that, although it was desirable that there should be consultations between Panel Committees about matters in which they were mutually interested, federation of such bodies was a dangerous thing to encourage, and might easily militate against the success of the Association in any fight it had to undertake. He hoped Panel Committees would leave those things in the hands of the central authority.

Captain FOTHERGILL preferred the word "conferences" to "federations."

Dr. BUIST said they had had a favourable experience of provincial conferences in Scotland.

On Captain FOTHERGILL's suggestion, which was accepted by the Oldham Representative, the motion was amended, and was carried in the following form:

That conferences of neighbouring Local Medical and Panel Committees held to exchange information and for the discussion of problems peculiar to the conditions of practice in their own areas with a view to securing concerted action thereupon, through the British Medical Association, should be encouraged by the Insurance Acts Committee.

THE FUTURE OF INSURANCE PRACTICE.

Dr. BRACKENBURY, in introducing the interim report on the future of the Insurance Acts, said that there were some points in it upon which an exchange of ideas would be useful. It was an interim report only, and the final report which would be arrived at in two or three months' time might be very different; but this report had been received with a very large measure of approval throughout the country. He invited suggestions through Divisions and Local Medical and Panel Committees, in order that all the matters contained in the report might be co-ordinated and taken into consideration.

Dr. D'EWART (Manchester) said that a considerable opinion in the country, while passively accepting the principles of the Insurance Acts, did not really approve of them, and did not desire any extension of them. He moved as a rider that no further steps be taken on the question of the extension of insurance until a referendum of the profession had been taken with this direct question.

Dr. BRACKENBURY said that considerations as to what extension meant and would involve and the consequential changes were all set forth in the interim report, and every Division and Branch was invited to express opinions thereupon. When these opinions were finally collated, they would be in a position to judge what the general opinion of the profession was. Manchester, they knew, took a peculiar view about these things. Manchester was

in a minority of one on one of the most important questions put to and answered by the local areas.

On a show of hands, the CHAIRMAN declared Dr. D'EWART's rider lost by a very large majority.

Dr. W. J. YOUNG (Cambridge and Huntingdon) thought that some of the answers received showed the futility of certain of the Divisions. As between leaving the matter to the Divisions or to the Council, he would plump for the Council every time.

Dr. G. E. HASLIP (Westminster) said that he had no wish to slay the slain, but he would like to point out a few questions to which, he thought, the Insurance Acts Committee might give a little further consideration. The first thing that was said when the profession fought the Insurance Act was that they would be free of the control of the approved societies. He would like all the Divisions to consider whether they were free of the approved societies. If they were free of local approved societies, were they free of the large institutions—the insurance companies? Out of the 14 millions of insured persons how many were direct contributors to the State? Quite two-thirds were in the large insurance companies, which had their agents distributed in all parts of the country. These agents were upon local committees; mixing with the classes with which they came in contact through insurance, they had certain political power. He hoped the Council would give serious consideration to this and other points which arose out of the question. Another matter was the extension of the Act to dependants. This meant more officials and greater cost. Was that cost going to be taken out of the remuneration of the doctors? In his Division they believed that to make the Act a success in populous districts they should have local clinics; by that means they felt that the work would be done very much better.

Dr. J. R. RATCLIFFE (Birmingham Central) objected to the "penny each, two for three ha'pence" method of payment for dependants. The incidence of sickness in the general run of cases did not justify this, and to take two or more children at a reduced fee would be dangerous. He strongly urged that wherever children or dependants were insured the full capitation fee should be paid for each.

Dr. H. F. OLDHAM (Lancaster) asked, in order that the synopsis of replies received to the questions might be appreciated at its true value, how much overlapping there had been. He himself could have given an answer three times over to these questions.

Dr. BRACKENBURY said that care had been taken in obtaining the replies to avoid overlapping as far as possible. The conditions in Lancashire were rather difficult from the point of view of eliciting the opinion of the various areas, but he could assure Dr. Oldham that any banking up of opinion had occurred only very rarely. In reply to Dr. LEWIS-LLOYD, he said that the scheme of election of the Local Medical and Panel representatives on the Insurance Acts Committee would be referred to the Local Medical and Panel Committees before the Panel Conference was held.

Dr. J. STEVENS (Edinburgh) moved, and Dr. LUNDIE seconded, that in any amendment of the Acts, medical benefit should be limited to the necessitous, and that the rest of the public who were able to provide it for themselves should be left free to have their medical attendance under the conditions of private practice. This was put to the meeting and lost.

Dr. J. CLARKE (Woolwich and Lewisham) approved of every bit of the interim report, which had prepared them as an Association for any attacks of the enemy. He spoke as a non-panel doctor, but as one who under certain schemes was perfectly willing to come in.

Dr. BRACKENBURY said that the Committee was very grateful for such an expression of opinion. The Committee took immense pains to produce this report and to survey the whole question from a statesmanlike standpoint. The attack upon the position of the general practitioner was still in evidence, and in considering this report they should remember that while they might not like the extension of the Insurance Acts to the dependants of insured persons, the alternative was a whole-time salaried officer at a clinic.

On the motion of Dr. JAMES PATTON (Gateshead) the meeting called upon the Insurance Commissioners for additional remuneration commensurate with the increased cost of living.

Dr. J. R. RATCLIFFE drew attention to the regulations made with regard to the treatment of disabled men discharged from the army suffering from tuberculosis. These men were entitled to sanatorium benefit, but in his experience comparatively few of them applied, and there were no means of forcing these men into sanatoriums. He moved the reference of the whole question to the Council, and this was agreed to.

The Supplementary Report under this heading was then approved.

PUBLIC HEALTH AND POOR LAW.

Dr. E. J. DOMVILLE, Chairman of the Public Health Committee, submitted the reports of the Council under the heading "Public Health and Poor Law," and these were approved. On his proposition it was also agreed—

That the grants for nutrition and such like provided for young children by maternity and child welfare centres should not be made from Poor Law funds.

Dr. JOHNSON SMYTH (Bournemouth) moved that it be an instruction to the Council to inquire through the Divisions into the remuneration and conditions of service governing Poor Law appointments in Great Britain. The motion was lost.

HOSPITALS.

Dr. H. J. CAMPBELL, Chairman of the Hospitals Committee, moved that the principles first suggested in the Association's model scheme for the treatment of tuberculosis and approved in 1914, and set out again in SUPPLEMENT, May 5th, p. 97) be adopted by voluntary hospitals treating patients maintained by public funds, so as to avoid the services of the medical profession being given gratuitously to such patients whilst the hospitals at the same time continued their voluntary status as regards their purely charitable work.

This was agreed to, and a rider by Mr. BISHOP HARMAN was also adopted:

That it is the duty of the State to provide the accommodation needed for the medical and surgical treatment and care of the sick, wounded and disabled sailors and soldiers, and that if the voluntary hospitals be asked to assist in this work these hospitals should not, as is frequent at present, provide for the accommodation of the sailors and soldiers by the sacrifice of facilities for the medical and surgical treatment and care of the civilian sick poor.

Mr. Bishop Harman said that the motion was a protest against the scandalous fashion in which the poor were deprived of their proper facilities for treatment at the voluntary hospitals. It was all very well at the beginning of the war, but it was quite another thing to keep such wards still tenanted. The fault was not entirely that of the War Office; it was mainly the fault of the hospital authorities, who wished to use the soldiers as an advertising medium for their institutions.

Dr. C. E. ROBERTSON (Glasgow) protested against the last statement. He did not think the governors of any hospital used the soldiers as an advertising medium. He was quite sure that what was being done had a grander and more patriotic motive.

Dr. BRACKENBURY said that an arrangement which the Advisory Committee had tried to make with the Ministry of Pensions with regard to payment for the treatment of soldiers and sailors in voluntary hospitals had fallen through, and it would be necessary for the staffs of the hospitals themselves to take action.

Major McADAM ECCLES (Marylebone) referred to a document just issued by the Ministry of Pensions, governing payment for the treatment of discharged sailors and soldiers at voluntary hospitals. The payment was not to exceed, except with the sanction of the Minister of Pensions, 21s. weekly at convalescent homes, and 28s. weekly at other institutions, including ordinary civilian hospitals. There was no reference to any other payment which could go to the medical officers of these institutions. It was also stated that where out-patient treatment was given at an institution the fee payable by the local committee should not exceed 1s. for the first and 6d. for each subsequent visit, while 1s. 6d. was put down for special treatment, including x rays. He moved:

That the question of the payment for treatment of discharged sailors and soldiers at voluntary hospitals be referred to the Council for consideration and such action as may be found necessary.

Dr. CAMPBELL (Chairman of the Hospitals Committee) pointed out that the Pensions Committee—so he understood—were being instructed to approach the local hospitals one by one and attempt to get them to agree to these utterly inadequate terms. Hence it was not a general proposal, but a specific proposal to each voluntary hospital. In certain areas the hospitals had been offered even smaller sums than those mentioned in the document to which Major Eccles had referred.

Major Eccles's motion was carried, and the reports under "Hospitals" were approved.

SCOTLAND AND IRELAND.

Dr. JOHN ADAMS, Chairman of the Scottish Committee, in moving the approval of the Annual and Supplementary Reports of the Council under that heading, reviewed the work of the Medical Service War Emergency Committee of Scotland and the inquiry it had conducted as to the opinions held among the profession in Scotland with regard to compulsory mobilization. In Scotland also they were in process of forming a special subcommittee to deal with questions under the Insurance Act. This did not mean merely looking after the interests of panel practitioners, although the men on the committee would mostly be panel men, because after all the panel interests of most general practitioners were far smaller than their other interests which they had in common with all general practitioners.

The reports were approved, as also were those under heading "Ireland," moved by Dr. J. S. DARLING (Portadown and West Down) in the absence of the Chairman of the Irish Committee.

NAVAL AND MILITARY.

The Indian Medical Service.

On the motion of the CHAIRMAN it was resolved that the following be appointed representatives of the Services on the Council for the period 1917-20:

Royal Navy Medical Service: Fleet Surgeon F. D. Lumley, R.N.(ret.).

Army Medical Service: Colonel R. I. D. Hackett, A.M.S.(ret.).
Indian Medical Service: Lieut.-Colonel R. H. Elliot, I.M.S.(ret.).

In the absence of the Chairman of the Naval and Military Committee, Lieut.-Colonel R. H. ELLIOT moved:

That the Representative Body approves the memorandum submitted by the Council on that part of the Report of the Royal Commission on the Public Services in India which deals with the Indian Medical Service.

Lieut.-Colonel Elliot dealt in feeling terms with the Report of the Royal Commission and the injustices under which the men of the Indian Medical Service had to labour. It was preposterous that the opinion of a surgeon-general should be liable to reversal at the dictation of a young civilian who knew nothing whatever about medical matters. Yet in point of fact that was what was happening frequently all over India, and it would continue to happen until the Director-General and the Surgeon-Generals were made secretaries to their Government. The biggest question of all was the right of private practice. It was not possible for the profession to dictate to the Secretary of State, but they could find out from him clearly what terms he meant to give the young medical officer of the future, and advise accordingly.

The meeting listened to Lieut.-Colonel Elliot with evident sympathy, and the motion was carried, as also a further motion, proposed by him, approving the remainder of the Report of the Council under heading "Naval and Military" (SUPPLEMENT, July 7th, p. 8).

ELECTION RETURNS.

In the course of the proceedings the CHAIRMAN and MEDICAL SECRETARY announced the results of elections as these were determined. The returns were as follows:

Chairman of Representative Body, 1917-18 (only one nomination):
Mr. F. B. TURNER.
Deputy Chairman (only one nomination): Dr. T. W. H. GARSTANG.

Election of Four Members of Council by Representative Meeting.
Dr. E. J. DOMVILLE. Dr. W. JOHNSON SMYTH.
Major ALBERT LUCAS. Dr. T. JENNER VERRALL.

Election of Twelve Members of Council by Grouped Representatives
(contest only in the first of the following groups).
Major A. C. FARQUHARSON: North of England, North Lancashire and South Westmorland, and Yorkshire Branches.
Dr. I. W. JOHNSON: Lancashire and Cheshire Branch.

Colonel C. H. MILBURN: East York and North Lincoln, Midland, Cambridge and Huntingdon, East Anglian, and South Midland Branches.
 Dr. H. C. MACRIER: Birmingham, Staffordshire, North Wales, Shropshire and Mid-Wales, and South Wales and Monmouthshire Branches.
 Mr. N. BISHOP HARMAN: Metropolitan Counties, Inner Group.
 Dr. R. LANGDON-DOWN: Metropolitan Counties, Outer Group.
 Dr. S. NOY SCOTT: Bath and Bristol, Gloucestershire, West Somerset, Worcestershire and Herefordshire, Dorset and West Hants, South-Western, and Wiltshire Branches.
 Captain E. R. FOTHERGILL: Oxford and Reading, Southern, Kent, Surrey, and Sussex Branches.
 Lieut.-Colonel J. MUNRO MOIR: Aberdeen, Northern Counties, Dundee, Perth, Edinburgh, and Fife Branches.
 Dr. J. MILLS: Connaught, South-Eastern of Ireland, and Leinster Branches.
 Dr. J. S. DARLING: Munster and Ulster Branches.

Election of Twelve Members of Insurance Acts Committee (contest only in Metropolitan Counties, Outer Group).

Major A. C. FARQUHARSON: North of England, North Lancashire and South Westmorland, and Yorkshire Branches.
 Dr. J. RATCLIFFE-GAYLARD: Lancashire and Cheshire Branch.
 Dr. C. J. PALMER: East York and North Lincoln, Midland, Cambridge and Huntingdon, East Anglian, and South Midland Branches.
 Dr. W. B. CRAWFORD TREASURE: Birmingham, Staffordshire, North Wales, Shropshire, and Mid Wales, and South Wales and Monmouthshire Branches.
 Dr. B. A. RICHMOND: Metropolitan Counties, Inner Group.
 Dr. J. A. P. BARNES: Metropolitan Counties, Outer Group.
 Dr. R. HARDING: Bath and Bristol, Gloucestershire, West Somerset, Worcestershire and Hereford, Dorset and West Hants, South-Western, and Wiltshire Branches.
 Captain E. R. FOTHERGILL: Oxford and Reading, Kent, Southern, Surrey, and Sussex Branches.
 Dr. JOHN HUNTER: Aberdeen, Northern Counties of Scotland, Dundee, Perth, Edinburgh, and Fife Branches.
 Dr. JOHN ADAMS: Glasgow and West of Scotland, Border Counties, and Stirling Branches.
 Dr. J. S. DARLING: Munster and Ulster Branches.
 No nomination: Connaught, South-Eastern of Ireland, and Leinster Branches.

CLOSING PROCEEDINGS.

Dr. MACDONALD having moved that, subject to the amendments and other resolutions adopted by the meeting, the Annual and Supplementary Reports of the Council be approved as a whole, this was carried *unanimously contra-dicente*.

The CHAIRMAN said that the Association owed a debt of gratitude to the Representatives who had come, in spite of the great pressure at the present time, and had got through the business in so thorough and determined a fashion.

Major WALLACE HENRY moved a very hearty vote of thanks to the Chairman, and this was seconded by Dr. JENNER VERRALL, and carried by acclamation.

Mr. TURNER, in reply, said that it had been a great pleasure to him to preside. He feared they had found him something of a slave-driver, but he could assure them that if they met under circumstances of greater leisure they would find him one of the most indulgent of chairmen.

On the motion of Major RUSSELL COOMBE, the staff were thanked for the way in which they had contributed to the expeditious carrying out of the business of the meeting.

The proceedings then concluded.

Meetings of Branches and Divisions.

CAMBRIDGE AND HUNTINGDON BRANCH.

THE seventy-third annual meeting of the Branch was held at Cambridge on July 11th, when the following officers were re-elected:

President: Dr. Grove. *Vice-Presidents:* Drs. Meacock and Newton.

Honorary Secretary and Treasurer: Dr. Ezard.

Representative: Dr. Young.

Joint Disablement Committee.—Lieut.-Colonel WHERRY was elected to represent the area on the Norfolk, Suffolk, and Cambridgeshire Joint (Disablement) Committee, subject to his consenting to serve.

Attendance on Discharged Sailors and Soldiers.—The following resolution, reported by the Cambridge and Huntingdon Division, was endorsed by the Branch:

That this Division recommends that payment for the treatment of discharged sailors and soldiers be made upon the attendance scale laid down in Army Form O. 1667.

INSURANCE.

LOCAL MEDICAL AND PANEL COMMITTEES.

COUNTY OF FORFAR.

At an adjourned meeting of the Local Medical Committee on July 4th it was resolved to disapprove of the Interim Report of the Insurance Acts Reconstruction Subcommittee of the York Local Medical and Panel Committee, and to uphold the policy of the British Medical Association.

Dr. Burgess (Forfar) and Professor Kynoch (Dundee) were nominated for vacancies on the new Statutory Advisory Committee under Section 58 of the National Health Insurance Act, 1911.

It was decided to inform the Secretary of the Scottish Association of Insurance Committees that the provision of a clinic in Forfarshire was unnecessary, and that there was at present no difficulty in getting specialists and consultants in the area.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty:—
 Surgeon-General D. T. Hoskyn has been placed on the retired list.
 Fleet Surgeon M. J. Smith, M.D., to the *Fivid*. Surgeon R. M. Riggall granted the acting rank of Staff Surgeon. Surgeon A. R. Sharrod, M.B., to the *Victory*. Temporary Surgeons: H. A. L. Guthrie to the *Pembroke*, additional for Chatham Hospital; W. W. Forsyth, M.B., J. F. Fleming, M.B., and L. H. Horsley, M.B., to Chatham Hospital; J. L. Owen, M.B., to the *Victory*; R. G. Melrose to the *Fivid*; J. G. Pearson, M.B., H. Robertson, M.B., and F. W. Poole to Plymouth Hospital; P. E. F. Frossard to the *Drake*. To be temporary Surgeons: H. C. C. Joyce, H. R. Buttery, F. W. Leech, M.B., T. O. Clark, M.B., F. R. Law.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon W. G. Evans, M.D., to the *Pembroke*. Surgeon probationer D. C. Lamond has been granted a temporary commission as Dental Surgeon. To be Surgeon probationers: R. M. Galloway, H. D. Low, J. Reid, G. Burnett, G. P. Monk, E. R. Murray, G. Tudhope, H. R. Griffith.

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS.

Temporary honorary Lieut.-Colonel Sir J. Collie, M.D., to be temporary honorary Colonel.

Sir A. MacCormick, M.D., F.R.C.S., to be temporary Colonel. Lieut.-Colonels to be temporary Colonels whilst employed as Assistant Directors of Medical Services of a Division: G. G. Delap, D.S.O., G. A. T. Bray.

To be acting Lieut.-Colonels: Majors M. W. Falkner, F.R.C.S.I., and W. MacD. MacDowall whilst in command of a stationary hospital; Captain E. W. Wade, M.B., whilst in command of a field ambulance; Major (Brevet Lieut.-Colonel) P. H. Henderson, D.S.O., M.B., whilst employed as Assistant Director of Medical Services of a Division; Major J. A. Hartigan, D.S.O., M.B., whilst in command of a casualty clearing station.

C. T. Parsons, M.D., to be temporary Lieut.-Colonel whilst employed at the Fulham Military Hospital.

Temporary Major R. L. Guthrie, M.D. (Captain R.A.M.C.T.F.) having ceased to be employed with the Fulham Military Hospital relinquishes his temporary commission.

T. M. Martin, M.D., to be temporary Major.

F. P. Nunneley, M.D., to be temporary honorary Major.

Temporary Captain H. D. Gillies, F.R.C.S., to be temporary Major.

The following officers relinquish their commissions:—Temporary Captains: F. L. Hill, M.D., A. E. London, M.D., S. S. Ball, M.B., T. O. Hutton, M.B., W. J. Grant, M.D., W. J. Patterson, M.B., E. W. Anderson, M.B., G. A. Pringle, M.D., R. A. Facey, D. Tenison, T. J. Phillips, M.B., A. Hallidie, M.B., F.R.C.S., A. W. Senior, G. H. Simpson, A. O. Sturdy, F.R.C.S., C. V. Cornish, F.R.C.S., G. F. Laing, M.D., J. Russell, M.D., W. S. O. Waring, M.B., C. H. Evers, J. E. Long, M.D., E. F. Clowes, H. W. Drew, F.R.C.S., D. F. Shearer, M.B., F.R.C.S., J. D. Harmer, M.B., F.R.C.S., J. Corcoran, G. B. Hillman, J. M. Keegan, M.B., F.R.C.S., T. E. Cottu, J. E. Paterson, M.B., E. A. Wilson, M.D., A. E. Hutton, A. B. Gordon, M.D., F.R.C.S., J. F. Coates, M.D., H. P. Sheppard, M.B., T. J. Costello, M.D., C. B. Kidd, M.D., E. S. Holloway, M.B., G. S. Coghlan, A. S. Gillett, T. Bell, M.D., H. M. Macgill, M.D., W. S. Finch, C. G. Monro, M.B., J. T. Myles, M.D., F.R.C.S.I., N. C. Wallis, C. B. Wainwright, M.B., N. S. Whitton, M.C., M.B., C. C. Holman, M.B., F.R.C.S., S. J. Staples, M.B., J. McGrath, M.B., F. L. Apperly, Harold Gray, W. S. Pratt, M.D., B. Lyons, M.B., J. Kirk, M.D., B. B. Metcalfe, R. Craven, M.B., C. T. Parsons, M.D., H. S. Smith, M.B. (on account of ill health). Temporary Lieutenants: C. C. Fissette, M.D., R. H. Lee, M.D., E. Connell, C. C. Coghlan, P. J. Rooney, A. L. White, F.R.C.S.E., F. C. V. Thompson, R. McLaren, J. Sterry, E. Fidler, M.B.

Temporary Lieutenants to be temporary Captains: H. F. Fenton, M.P., L. E. Bolster, M.B., C. T. Cheadle, P. G. Russell, C. E. Barlett, H. J. Bensted, H. B. Jones, M.B., P. J. Lydon, M.B., J. P. Good, M.D., W. McKee, M.B., H. C. Nickson, M.B., L. M. Reston, M.B., W. Niccol, M.B., F. S. Machin, B. Wood-White, M.B., A. A. Lees, C. G. Teall, M.B., J. L. Gordon, M.D., W. J. P. Lillis, C. W. Budden, M.D., J. A. Dickson, M.B., A. R. Lindsay, M.B., C. J. McN. Willoughby, M.B., P. A. Sarjeant, M.B., L. R. Hill, J. A. Stanley, M.B., J. Lindsay, M.B., P. H. Cooke, A. W. Ritchie, M.D., S. Samuel, M.B., G. E. Charters, M.D., R. H. Astbury, M.B., W. T. Currie, M.B., S. G. Scott, M.B., W. S. Booth, M.B., A. J. Neillan, M.B., R. W. Light, M.B., W. L. Millar, M.B., F. H. Pickin, A. Cleland, M.B., A. J. Caird, M.B., J. D. Macfie, M.B., H. M. Cade, R. T. G. Atkin, M.D., J. B. Mason, A. R. G. Milton, B. T. Parsons-Smith, M.D., J. M. Kelly, M.D., A. H. Turner, W. Balgarnie, M.B., F. R. C.S., H. G. Smith, M.B., A. V. Dill, M.B., W. M. Jeffreys, M.B., M. Lyons,

F. G. D. Murray, D. K. Henderson, M.D., J. H. Wilson, M.D., P. S. MacLaren, M.D., A. H. Turner, M.K. Robertson, P. K. McCowan, M.B., P. W. Dove, M.B., C. P. Charles, R. C. Crawford, M.B., P. C. West, M.B., T. D. Morgan, H. A. Tillman, M.D., J. Butler, M.B., J. M. Taylor, M.B., C. J. D. Bergin, G. B. Wild, A. W. George, M.B., R. H. Smythe, E. H. Morris, H. W. Garden, M.B., S. B. Hanbury, J. W. Cowie, F. H. Storey, M.B., H. M. Leathes, W. H. Booth, J. C. N. Harris, H. C. Wilson, M.D., F.R.C.S., R. H. Ratray, E. R. Bastard, C. S. O'Neill, M.D., H. C. Harper, A. B. Howitt, M.D., D. N. Knox, M.B., E. G. D. Milsom, E. G. H. Weir, M.D., E. Rommel, R. Maclean, E. W. H. Cruickshank, M.B., J. M. Kelly.

Temporary Lieutenants Robert Orr, M.B., and Donald M. M. Ross, M.B., are dismissed the service by sentence of a general court-martial.

Temporary Lieutenant Robert Hugh Cotton is cashiered by sentence of a general court-martial.

F. Coates, M.D., to be temporary honorary Lieutenant.
To be temporary Quartermasters, with the honorary rank of Lieutenants: W. E. Maitland, P. J. Watkins, W. G. Wilmsburst, A. W. Shreeve, G. Carroll, W. H. Tonks, E. C. Sherwood, E. J. Trafford, A. N. Girling.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

To be Lieutenants: W. Eidinow and A. G. F. McArthur from University of London Contingent O.T.C.; A. B. Platt, M.B., E. N. P. Martland, M.B., W. T. G. Boul, M.B., from Manchester University Contingent O.T.C.; J. A. Keen from University of London Contingent O.T.C. (substituted for notification in the *London Gazette* of May 25th, 1917), C. G. Irwin, M.B.

OVERSEAS CONTINGENTS.

CANADIAN ARMY MEDICAL CORPS.

Temporary Major H. E. Kendall to be acting Lieutenant-Colonel whilst in command of a Canadian Stationary Hospital.
Temporary Captains to be temporary Majors: E. S. Jeffrey, D. J. Cochrane.

To be temporary Captains: I. W. Dickson, G. F. Laing, M.D.

HOSPITAL TREATMENT OF DISCHARGED DISABLED MEN.

THE POSITION OF STAFFS OF VOLUNTARY HOSPITALS.

THE following letter has been addressed to the secretaries of the honorary medical staffs of voluntary hospitals with reference to the instruction of the Ministry of Pensions to the local Pensions Committees empowering the Committees to refer discharged disabled soldiers and sailors to general hospitals:

British Medical Association,
429, Strand, London, W.C.2.
August 8th, 1917.

Dear Sir,

The Ministry of Pensions has recently issued to Local Pensions Committees a Book of Instructions and Notes on the Treatment and Training of Disabled Men. *Inter alia* these Instructions empower the Committees to refer discharged disabled soldiers and sailors to general hospitals for special treatment as in- or out-patients when no military hospital is available.

Accordingly most Pensions Committees will shortly be trying to make arrangements with the governing bodies of civil hospitals for the treatment of men for whose treatment the Committees are responsible. According to Schedule I of the Instructions referred to above—

The weekly charge for in-patient treatment for which the Local Committee may accept liability shall not exceed (except with the sanction of the Minister of Pensions) the minimum charge made in the case of ordinary patients by the managers of the Institutions, and shall in no case exceed (except with such sanction)

the sum of 21s. weekly in the case of convalescent homes
the sum of 28s. weekly in the case of other institutions.

In any case where out-patient treatment is given at an institution the fee (if any) payable by the Local Committee shall not exceed 1s. for the first and 6d. for each subsequent attendance of the patient, unless treatment consists of or includes massage, electrical, x-ray, or other special form of treatment, in which case the fee shall not exceed 2s. 6d. for the first visit, and 1s. 6d. for each subsequent visit to include all services.

In pursuance of its policy that the services of the medical profession should not be given gratuitously to patients who are maintained by public funds, the British Medical Association desires to call the attention of the staff of your hospital to the serious position which now arises. By the proposed arrangements between Local Pensions Committees and general hospitals many State-maintained patients will shortly be treated in these institutions, and it seems to be assumed that the members of the medical profession will give their services gratuitously though the hospitals will be paid for maintenance. In the opinion of the Association it will be most unfortunate if this assumption is allowed to go unchallenged.

At a deputation from the Association which was received by the Minister of Pensions on May 15th, 1917, Mr. Barnes asked the Association to nominate three members of a Medical Advisory Committee which he proposed to consult on matters specially affecting the profession, and Drs. H. B. Brackenbury and Alfred Cox and Mr. Bishop Harman were nominated. To these the Minister added Sir Frederick Taylor, Bt., and Dr. Sidney Martin from the

Royal College of Physicians of London, and Sir W. Watson Cheyne, Bt., and Sir J. Rickman Godlee, Bt., from the Royal College of Surgeons of England. After the first meeting of that Committee, at which the subject now under discussion was discussed, the letter which is appended (Appendix A) was sent to the Ministry by Sir Rickman Godlee writing on behalf of all the members of the Medical Advisory Committee. The reply was to the following effect: That the instructions for treatment and training of discharged soldiers were, after prolonged consideration, being circulated to Local Committees, and their issue could not be suspended to allow of the consideration of the big question raised, which was not one affecting the Ministry alone. Other public departments and local bodies were, using both general and special hospitals for treatment, and have been doing so for some years on the basis of payment of the charges made by the Institutions for the individual cases sent, and these departments and bodies would have to be consulted before the Ministry could inaugurate a new policy of special payment for the services of the hospital staff in addition to the charge made for the bed. The Ministry was in a different position from that of the local authorities referred to, and it was thought that the Minister could not pronounce in favour of the suggestion made, as a general principle, without raising the whole question of the responsibility of the hospitals to public authority in the matter of their staff.

The Association places these facts before the members of your Staff in the hope that if your hospital is being asked to treat discharged disabled men the Staff will at once meet to consider the matter, and will, it is hoped, inform the governing body of the hospital that these cases cannot be treated as a matter of charity.

I append a scheme (Appendix B.) approved by the Association for dealing with similar cases, by means of which it is believed that State-aided patients may be dealt with without infringing the honorary character of the general work of the staff. It is very difficult at the present time to suggest the payment which medical staffs should demand to be earmarked for the medical treatment of each case, as the cases vary so much in difficulty and in the amount of work which they entail. It is advisable that for the present a purely experimental arrangement should be made which would be subject to adjustment in the light of experience.

I am instructed to express the hope that your Staff, realizing the importance of this matter, will be good enough to inform the Association:

(1) If any Local Pensions Committee has entered into arrangements with your hospital.

(2) What action your Staff has taken or proposes to take.

(3) What arrangement has been made for the earmarking of part of the money received on behalf of disabled men for the use of the medical staff, and to what use it is intended to put the money so earmarked.

A copy of a letter addressed to the Governing Bodies of Voluntary Hospitals is enclosed.

I am, yours faithfully,

ALFRED COX,
Medical Secretary.

To the Secretaries of the Honorary
Medical Staffs of Voluntary Hospitals.

APPENDIX A.

COPY OF A LETTER SENT ON BEHALF OF THE MEMBERS OF
THE MEDICAL ADVISORY COMMITTEE TO THE
MINISTRY OF PENSIONS.

19, Wimpole Street, W.,
June 28th, 1917.

Dear Sir,

Since the members of the Medical Advisory Committee met you on the 4th inst., the subject of the admission to voluntary hospitals of discharged men for special treatment had been discussed by us, and we have unanimously arrived at certain conclusions which I wish on their behalf to place before you in order, if possible, to influence the nature of the proposals to be made on behalf of the Ministry of Pensions to those voluntary hospitals which may be asked to receive cases.

You will remember that in the draft circular you submitted to us on the 4th inst., it was proposed that 28s. per week should be paid to voluntary hospitals for each in-patient treated, and the question was asked whether or not this sum included any payment for the medical men who gave the treatment. You stated that it did not, and after a discussion, in which it was evident that the opinion of the members of the Advisory Committee was divided, you came to the conclusion that the matter had better not be mentioned in the circular but be left to be raised by any hospital whose staff desired payment.

On further consideration we think this would be a mistake, for the matter is bound to be raised soon, and we believe it had better be dealt with centrally than left to be a bone of contention between Local Pensions Committees and hospitals. Some hospitals would apply for payment for their staffs and some might not. If this were so and payment were made to the former there would be suspicion of differential treatment which we believe would be most unfortunate. If payment were refused we have reason to believe that there would be much dissatisfaction on the part of medical men, who hold strongly that they ought not to be expected to give their services as a charity to persons for whom the State is responsible. We think these risks should be avoided by a statement on the part of the Ministry that the medical men who give the treatment to patients for whom you are responsible will be paid. There is precedent for this. The London County Council, for example, refers large numbers of school children to voluntary hospitals in London for treatment of eye and throat affections, and, besides making a payment towards the hospital funds, the Council earmarks a definite separate payment for the doctors who do the work. There is also an arrangement in the County of Durham whereby the County Council pays a flat rate of £2 for every case of surgical tuberculosis admitted to certain hospitals on the recommendation of the County Council. This amount is paid over to the medical staff.

It is very difficult to suggest the appropriate rate of payment for the class of cases now under consideration. We should, however, be willing to go further into the matter and present a scheme if you should consent to adopt the principle that any payments made to voluntary hospitals for the treatment of men for whom the Ministry is responsible shall include an amount earmarked for the medical staff and entirely at their disposition.

I am, yours faithfully,

RICKMAN J. GODLEE.

Colonel Sir A. Griffith-Boscawen, M.P.,
Ministry of Pensions.

Appendix B, containing the suggestions of the British Medical Association to members of the honorary medical staffs of voluntary hospitals for dealing with the question of State-aided patients receiving treatment at their hospitals, was published in the Annual Report of Council in the section dealing with hospitals (SUPPLEMENT, May 5th, p. 98).

A letter has also been addressed to the secretaries of the governing bodies of voluntary hospitals pointing out that as the voluntary hospitals throughout the country are at present only able with difficulty to cope with the work entailed by the care of the sick poor, this extra work which it is proposed to throw upon them can only in most cases be undertaken by an extension of the accommodation for in-patients and of the arrangements for the care of out-patients. The hope is expressed that, in taking into consideration the question of the adequacy of the payments suggested, the governing body will agree with the opinion of the British Medical Association that not only maintenance but also professional attendance should be paid for by the State, and the hospital board is asked before agreeing to terms to take the opinion of its honorary medical staff on the whole question.

MEDICAL OFFICERS FOR THE ARMY.

PROPOSED COMMITTEE OF INQUIRY.

At a joint meeting of the Committee of Reference of the Royal Colleges in England and the Central Medical War Committee on August 15th, the position disclosed by the letter addressed to the Secretary of State for War on August 3rd and printed in the SUPPLEMENT last week, p. 35, was further considered. The letter, it will be remembered, stated that in the opinion of the Central Medical War Committee no more medical men from England and Wales could be called upon to take commissions in the army without seriously endangering the supply of doctors for the treatment of the civil community, and that further depletion could only be effected on the responsibility of the Government after carefully comparing the military with the civil needs. In the course of the discussion it was pointed out that a widespread feeling appeared to exist among medical men, both inside and outside the army, that something could be done to relieve the situation by better organization in the use made of the personnel of the R.A.M.C. At the conclusion of the discussion the Committee adopted the following resolution, which was directed to be sent to the Prime Minister, the Secretary of the War Cabinet, the Secretary of State for War, and the Director-General A.M.S.:

The Central Medical War Committee understands, from reports of the proceedings in Parliament, that the Government has in contemplation the appointment of a small committee of inquiry into the practical working of the Army Medical Service in the field. The Committee welcomes this announcement, believing from statements made to it that such an inquiry is certainly advisable, and is calculated to allay much unrest. The Committee trusts, however, that the inquiry will be extended to include the working of the service in this country. The Committee suggests that in view of the difficulty of supplying from the civil community more doctors for the army the reference to the committee of inquiry should include the duty of instituting a careful comparison between the medical needs of the civil community and the army respectively. The Central Medical War Committee would venture to urge that, in view of the responsibility which has rested on it of selecting from civil practice the bulk of the doctors now serving in the army, the committee of inquiry should include representatives of the Central Medical War Committee.

LOCAL MEETINGS OF PRACTITIONERS.

BUCKINGHAMSHIRE.

A MEETING of practitioners, convened by the Local Medical War Committee, the Buckinghamshire Division of the British Medical Association, and the Local Medical and Panel Committees, was held at Aylesbury on July 19th.

Local Medical War Committee.—It was decided to accede to the request of the medical men practising in the Eton Union district that they should have four representatives on the Local Medical War Committee, as it was impossible for any one man to guarantee to be always present, on the understanding that if all four were present at a meeting the votes of two only should count in any decision.

The following were elected as the Local Medical War Committee:—*North Bucks:* Drs. Benson, Bradbrook, Harris, Chignell, Kennish, and Larking. *Mid Bucks:* Drs. Baker, Churchill, Long, Rose, E. O. Turner, Woollerton, and Smith-Wynne. *South Bucks:* Drs. Weaver Adams, Ansler, Selborne Bailey, Bell, Bieneman, Brooks, Dickson, Fraser, Harwood-Yarred, Reynolds, and Watson.

Ministry of Health.—After discussion the scheme of the British Medical Association with reference to a Ministry of Health was agreed to, with the exception that it was considered that the distinction between a State Preventive and a State Clinical department was inadvisable, and that there should be a chief medical officer over the whole. It was also agreed that in any system all branches of State medicine should be included, and the opinion was expressed that as there was no guarantee that any new committees dealing with public health would do any better than the present Public Health Committee of the county councils, the establishment of new local health committees was unnecessary. It was also agreed that, as part-time medical men did their work better than whole-time ones, having a smaller area to work in, the general practitioner should have as much of the work as possible,

and that the chief medical officer should have full control over departments such as school work, tuberculosis, venereal diseases, Poor Law infirmaries, lunacy institutions, maternity and child welfare, sanitation and infectious diseases. There should also be a department for research, statistics, etc., and two or more counties should unite in some instances.

Payments to Medical Officers to V.A.D. Hospitals.—A discussion on the payments of medical officers to V.A.D. hospitals led to various opinions being expressed, some being in favour of doing the work voluntarily and others that all ought to be paid.

INSURANCE.

NATIONAL INSURANCE ADVISORY COMMITTEE.

A LETTER has been received from the National Insurance Joint Committee notifying that the Chairman, Sir Edwin Cornwall, has sent invitations to the following to serve on the Advisory Committee:

Dr. Mabel L. Ramsay, Plymouth.	Dr. J. A. Macdonald, Taunton.
Dr. J. Singleton Darling, Lurgan.	Dr. Lauriston E. Shaw, London.
Dr. John Adams, Glasgow.	Dr. R. Wallace Henry, Leicester.
Dr. Norman Walker, Edinburgh.	Professor A. Bostock Hill, Birmingham.
Dr. E. J. Maclean, Cardiff.	Mr. E. B. Turner, London.
Dr. E. O. Price, Bangor.	Dr. A. Fulton, Old Basford.
Dr. T. Ridley Bailey, Gorleston.	Dr. Alfred Cox, London.

Dr. Brackenbury, whose name had also been suggested by the Association, is already a member of the Advisory Committee.

In acknowledging the receipt of this intimation, Dr. Cox, the Medical Secretary of the British Medical Association, stated that he was instructed by the Chairman of the Insurance Acts Committee to state that he considered it very unfortunate that two of the names forwarded by the Association—namely, Dr. Crawford Treasure and Dr. R. Harding—had been omitted from Sir Edwin Cornwall's selection, as preference for them was very clearly indicated by the large number of nominations received on their behalf from the Local Medical Committees of the country. It was pointed out also that an incidental result of the non-acceptance of these nominations was that the Advisory Committee now contained no representative of rural practitioners, though the list forwarded by the Association contained two names—Dr. R. Harding and Dr. T. Wood Locket.

LOCAL MEDICAL AND PANEL COMMITTEES.

BEDFORDSHIRE.

At a recent meeting of the Local Medical and Panel Committee a subcommittee was appointed to examine in detail the scripts of those eight doctors who had exceeded the average of eighteenpence per insured person on their list.

It was agreed that it was not desirable to have an election for the Panel Committee during 1917.

With reference to the British Medical Association's circular (M. 10) as to the future of the medical profession, the Committee was in favour of a unified system of public health under a separate Minister, but considered that it was of primary importance for the success and general acceptance of any scheme to secure the services of the family doctor and general practitioner.

At a meeting of the Local Medical Committee on the same day two representatives were nominated to serve on the Special Disablement Subcommittee of the Bedford War Pensions, etc., Committee.

DERBYSHIRE.

A MEETING of the Derbyshire Panel Committee was held on August 9th, when Dr. A. COURT was in the chair.

Specialist's Prescription.—In reply to a communication from the clerk to the Derbyshire Insurance Committee, it was resolved that if a panel practitioner continued expensive treatment prescribed by a specialist, who had been consulted without his knowledge or request, and which treatment was not approved by him, the panel patient should be held responsible for such expense.

Antitetanus Serum.—The question of the liability of a panel practitioner to pay for the cost of providing antitetanus serum was raised by another letter from the clerk to the Insurance Committee. It stated that application had been made to the Commissioners to authorize payment of the cost of the order, and that the Commissioners' reply was that the question was covered by the capitation payment under Clause XII (1) of the Panel Agreement, but that if the Insurance and Panel Committees desired that the clause be amended to admit of special payment the Commissioners would consider any proposals submitted. The Committee resolved:

That the use of the serum was necessary to the preservation of the patient's life; that the practitioner should not be called upon to pay for the serum; and that the cost of it should not be borne by the Drug Fund, but should be the subject of a special provision.

Tariff.—The Committee resolved not to accept the suggestion that the ratios between the prices of the two tariffs as ascertained for the first quarter of 1916 should be adopted for the year, on the following grounds: (1) The first quarter of the year is the heaviest, as it includes the largest amount of sickness. (2) The local pharmacopoeia came into use during that year with resulting economy. (3) In consequence of advisory warnings issued to the practitioners the expense of prescribing has decreased.

Votes of Thanks and Congratulations.—The resignation of Dr. Roberts on leaving the district to take up war work was accepted with regret, and the Committee expressed its appreciation of his valuable services. Votes of congratulation to Dr. Macdonald, J.P., on his appointment as alderman of the Derbyshire County Council, and to Dr. Smiley on his election to the chairmanship of the Derbyshire Insurance Committee, were adopted, and these gentlemen replied.

Association Notices.

THE LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

A LIST of periodical publications, official reports, and Blue Books in the Library of the British Medical Association available for issue to members on loan has been printed, and copies can be obtained free on application to the Librarian at the house of the Association, 429, Strand, W.C. The regulations governing the loan of these publications are stated in the introduction to the list. The Library is open for consultation from 10 a.m. till 5 p.m. (on Saturdays till 2 p.m.).

BRANCH AND DIVISION MEETINGS TO BE HELD.

NORTH OF ENGLAND BRANCH.—Dr. James Don, Honorary Secretary (1, Grove Street, Newcastle-on-Tyne), gives notice that the annual meeting of the North of England Branch will be held at 25, Ridley Place, Newcastle-on-Tyne, on Friday, September 7th, at 3.15 p.m.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty:—Surgeon-General P. B. Handyside, M.B., to Chatham Hospital. Fleet Surgeons K. A. Jones, M.B., to the *Pembroke*, additional, for medical transport duties; J. Whelan to the *Royal Arthur*; R. L. Jones to the *Victory*, additional. Staff Surgeon S. S. H. Shannon to the *Amphitrite*. Temporary Surgeons: F. W. Leech, M.B., T. C. Clark, M.B., and F. R. Law to Haslar Hospital; C. Colner, M.B., W. Everett, M.B., to Plymouth Hospital; K. B. Aikman to Chatham Hospital; D. Sutherland, M.B., to the *Victory*, additional; J. A. Hadfield, M.B., to the *Victory*, for Royal Naval Division.

ROYAL NAVAL VOLUNTEER RESERVE.

To be Surgeon probationers: A. G. Smith, S. W. T. Lee, A. E. Reid, D. R. Macdonald, T. H. Kirk, B. C. McLeannan, J. C. McNaught.

ARMY MEDICAL SERVICE.

ROYAL ARMY MEDICAL CORPS.

Honorary Lieut.-Colonel A. S. Woodward, M.D., to be temporary Lieut. Colonel.

J. F. O'Carroll, M.D., F.R.C.P.I., to be temporary honorary Lieut. Colonel.

Honorary Major S. W. Woollett to be temporary Major.

Lieut. Colonel W. T. F. Davies, D.S.O., M.B., late Imperial Light Horse, to be temporary Major (substituted for notification in the *London Gazette* of July 17th).

Vacancies and Appointments.

VACANCIES.

NOTICES REGARDING APPOINTMENTS.—Attention is called to a Notice (see Index to Advertisements—Important Notice re Appointments) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

Major W. L. Bennett, M.B., F.R.C.S.E., is placed on the half-pay list. Temporary Captain R. H. Bremridge, M.B., to be temporary Major. Officers T.F. to be granted temporary rank as stated:—As Lieut.-Colonel: Lieut.-Colonels J. Godding and J. W. H. Brown. As Major: Majors H. T. Jenkins, S. G. Ogilvy, M.D., J. Gott, T. W. Mead, J. A. Wait, M.B., W. E. M. Corbett, W. Murray, M.D., As Captain: C. W. Milner, F. R. Lucas, As Lieutenant: Lieutenant R. G. Oran. To be temporary Captains: Temporary Captain E. M. Lithgow, M.B., Royal Highlanders; J. J. Boyd, M.D., T. R. St. Johnston, W. P. H. Munden, M.D., C. A. Moseley, M.D., G. E. Manning, M.D., F.R.C.S., R. F. Gil, M.D., J. M. Renton, M.B., F.R.C.S.E., R. Milne, M.D., F.R.C.S., J. S. Joly, M.D., F.R.C.S.; temporary Captain O. R. M. Kelly, M.B., from general list. A. E. Lyster, M.D., and R. F. Yencken, late temporary Captains, to be honorary Captains.

Temporary honorary Captain C. F. R. McDowall, M.D., having ceased to be employed with the Moss Side Military Hospital, relinquishes his commission.

Temporary Lieutenants to be temporary Captains: D. McC. Aitken, M.B., F.R.C.S.E., J. E. Sandilands, M.D., R. Massie, F.R.C.S.E., W. P. Wippell, J. J. Anning.

The following officers relinquish their commissions: Temporary Captains H. J. M. Adams, M.B. (on account of ill health), N. E. MacDougall, M.D., M. C. Burke, M.C., M.D., F. J. Brodie, M.D., F.R.C.S.E., G. M. Gregoire, M.D., S. J. C. Fraser, M.D.; temporary Lieutenants D. North, A. H. McCandlish, and G. C. March (on account of ill health).

G. Hodge, M.B., to be temporary honorary Lieutenant whilst employed at the Springburn and Woodside Hospital.

To be temporary Lieutenants: H. L. Clift, M.B., J. R. Watson, M.B., W. J. Stephens, A. T. Mackenzie, M.D., F.R.S.E., S. Bree, M.B., S. G. Corner, M.D., D. A. Dewar, M.B., W. J. D. Brouley, M.B., T. Winning, M.B., A. Davies, M.B., R. Davidson, M.B., R. Wade, M.D., J. W. Simon, K. R. C. Hallows, M.B., F. D. Parbury, S. L. O. Young, M.D., N. McC. Hutchison, M.B., F. D. Nicholson, M.D., W. L. English, M.B., C. U. Whitney, T. B. Mitchell, M.B., E. Banks, M.B., P. T. J. O'Farrell, C. A. Joll, M.B., F.R.C.S., A. S. M. Pabner, M.D., E. E. Cassidy, M.B., I. D. Stamp, M.D., H. P. Dawson, M.B., A. M. Laurie, J. Donaldson, M.B., E. U. Williams, H. M. Reeve, M.B., M. F. Emrys-Jones, S. M. Vassals, M.D., W. G. Riley, M.B., J. F. Hornsey, M.B., A. Morton, M.B., A. Barker, D. Purdie, M.B., R. L. E. Downer, M.D., B. Barnett, J. P. Findlay, M.R., H. J. Beddow, N. Leonard, M.D., R. L. Haines, L. G. Teece, M.B., E. F. Thomas, M.B., A. D. Crofts, H. J. Rae, M.B., G. C. B. Mieville, C. W. Hutt, M.D., J. S. Mitchell, M.B., F.R.C.S.E., R. S. Roper, F.R.C.S.E., P. W. Stewart, M.B., F. F. Laidlaw, H. C. Martin, M.B., A. V. Ledger, M.D., J. Fletcher, M.B., N. C. Rogers, M.B., H. Snape, M.B., K. S. Melvin, M.B., J. R. Cameron, M.D., G. W. B. Shaw, M.B., H. H. Molloy, M.B., T. Miller, M.B., A. Robertson, M.B., N. Bradley, M.D., P. E. Carroll, M.B., H. J. Hoile, M.B., M. T. D. McMurich, M.B., A. Boyle, M.B., E. E. Atkin, M.B. L. T. Kewer to be temporary honorary Lieutenant.

To be temporary Quartermasters with the honorary rank of Lieutenant: J. O. Ibell, J. Tasker.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

To be Lieutenants: N. Kletz, M.B., and W. M. Jones, M.B., from Manchester University Contingent O.T.C.; R. D. Aylward, S. H. de G. Pritchard and P. W. A. Watt, from University of London Contingent O.T.C.; H. M. Holt, M.B., from Leeds University Contingent O.T.C.

OVERSEAS CONTINGENTS.

CANADIAN ARMY MEDICAL SERVICE.

Deputy Director of Medical Services: Temporary Colonel M. MacLaren, C.M.G., C.A.M.C.

Assistant Director of Medical Services: Temporary Lieut.-Colonel C. E. Doherty, C.A.M.C.

Deputy Assistant Directors of Medical Services: Temporary Major J. S. Jenkins, D.S.O., C.A.M.C., temporary Captain H. B. Logie, C.A.M.C.

CANADIAN ARMY MEDICAL CORPS.

Temporary Major J. C. Meakins to be acting Lieut.-Colonel while specially employed.

Temporary honorary Major J. W. Good resigns his temporary commission.

Temporary Captain A. L. Johnson to be temporary Major.

Temporary Captain R. J. McEwen to be acting Major while specially employed.

Temporary Captain H. G. Gillissie resigns his temporary commission.

To be temporary Captains: C. B. Kidd, A. F. Menzies, J. W. McIntosh, M.D., E. Fidler, M.D., A. W. Macbeth, E. Sheffield.

Temporary Lieutenant W. McL. Moore, from general list to be temporary Quartermaster with the honorary rank of Lieutenant.

H. A. Des Brisay, M.D., to be temporary Lieutenant.

SOUTH AFRICAN MEDICAL CORPS.

Temporary Lieut.-Colonel P. G. Stock, M.B., relinquishes his commission.

R. C. Mullins, M.D., to be temporary Captain.

TERRITORIAL FORCE.

ARMY MEDICAL SERVICE.

Captain H. F. Humphreys, M.B., to be Deputy Assistant Director of Medical Services.

ROYAL ARMY MEDICAL CORPS.

Major F. W. Johnson, M.B., to be acting Lieut.-Colonel whilst commanding a field ambulance.

Major (acting Lieut.-Colonel) G. Ashton, M.D., relinquishes his acting rank on ceasing to command a field ambulance.

Captain L. A. Dingley, M.D., to be acting Lieut.-Colonel whilst commanding a field ambulance.

Captain B. H. C. Lea-Wilson remains seconded for duty with the Egyptian Army.

Captain W. Seymour, M.B., is restored to the establishment.

Captains (temporary Majors) A. Young, M.B., and L. G. J. Mackey, M.D., relinquish their temporary rank on alteration in posting and are restored to the establishment.

Captain J. P. Fagan relinquishes his commission on account of ill health.

To be Lieutenants: Acting Sergeant Mark Canton, Lieutenant D. H. Burrell, from Special List; Staff Sergeant R. S. Moon.

BARNSELY AND WAKEFIELD JOINT SANATORIUM COMMITTEE. Assistant Tuberculosis Officer for the Borough, and Resident Medical Officer at Mount Vernon Sanatorium. Salary, £300 per annum.

Bristol Royal Infirmary.—(1) House-Physician; (2) House-Surgeon. Salary, £120 per annum.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—House-Physician. Salary, £150 per annum.

CHELTHAM EYE, EAR, AND THROAT FREE HOSPITAL.—Honorary Surgeon.

EASTBOURNE EYE INFIRMARY.—Ophthalmic Surgeon.

GREAT YARMOUTH: GENERAL HOSPITAL.—House-Surgeon (male). Salary, £200 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.—House-Physician. Honorarium, 30 guineas for six months.

KIRKSTALL: PARISH OF EDAY.—Medical Officer.

LEICESTER ROYAL INFIRMARY.—House-Surgeon. Salary, £250 per annum.

LINDSEY, COUNTY OF THE PARTS OF.—Lady Assistant Medical Officer of Health. Salary, £400 per annum.

LIVERPOOL EYE AND EAR INFIRMARY.—Lady House-Surgeon.

MAIDSTONE: WEST KENT GENERAL HOSPITAL.—1) House-Surgeon. (2) Assistant House-Surgeon. Salary, £250 and £125 per annum respectively.

MANCHESTER: ANCOATS HOSPITAL.—Resident (unqualified). Salary, £50 per annum.

MATERNITY AND INFANT WELFARE CENTRES OF KING EDWARD INSTITUTION, Albert Street, E.—Medical Officer for consultation weekly for antenatal clinic. Fee, 1 guinea.

NORTH-EASTERN HOSPITAL, St. Ann's Road, Tottenham, N.—Lady Assistant Medical Officer. Salary, 7 guineas per week.

NORWICH CITY ASYLUM, Hellesdon.—Assistant Medical Officer (male). Salary, £300 per annum.

ROCHESTER: ST. BARTHOLOMEW'S HOSPITAL.—Junior Resident House-Surgeon. Salary, £150 per annum.

ST. MARK'S HOSPITAL FOR CANCER, Etc., City Road, E.C.—House-Surgeon.

SALISBURY GENERAL INFIRMARY.—House-Surgeon. Salary, £150 per annum.

SHEFFIELD: JESSOP HOSPITAL FOR WOMEN.—Senior Lady House-Surgeon. Salary, £200 per annum.

SHEFFIELD ROYAL INFIRMARY.—Two House-Surgeons. Salary £120 per annum each.

SWANSEA EDUCATION COMMITTEE.—Lady Assistant School Medical Officer. Salary, £350 per annum.

WELSH METROPOLITAN WAR HOSPITAL, Whitechurch.—Resident Physicians with experience in the treatment of mental disorders.

WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.—House-Surgeon. Salary, £150 per annum.

WOOLWICH TUBERCULOSIS DISPENSARY.—Locumtenent.

To ensure notice in this column—which is compiled from our advertisement columns, where full particulars will be found—it is necessary that advertisements should be received not later than the first post on Wednesday morning. Persons interested should refer also to the Index to Advertisements which follows the Table of Contents in the JOURNAL.

APPOINTMENTS.

BETTERIDGE, T., M.B., B.C. Cantab., District Medical Officer of the Tamworth Union.

BUTLER, L. H., M.B., Ch.B. Leeds, Certifying Factory Surgeon for the Castleford District, co. Yorks.

DRAKE, D. J., M.R.C.S., L.R.C.P., District Medical Officer of the Faversham Union.

HASLUCK, E. P., L.R.C.P. and S. Edin., District Medical Officer of the Wellington (Somerset) Union.

HUNNARD, A., M.B., B.S. Lond., Visiting Surgeon at the Mansfield Union Workhouse.

JEFFERISS, I. M., M.R.C.S., L.R.C.P., District Medical Officer of the Medway Union.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTHS.

JACK.—At Kendal, on August 5th, the wife of Wm. B. Jack, M.D., Lieutenant R.A.M.C., a daughter.

STATHERS.—On August 12th, at The Elms, Turweston, Brackley, the wife of Surgeon Gerald Stathers, R.N., a daughter.

CURRENT NOTES.

Petrol for Medical Practitioners.

In the JOURNAL of August 4th (p. 159) we stated certain facts as to the position as regards the supply of petrol to medical practitioners for use in professional work. As from August 1st, 1917, the Petrol Control Department is issuing no new licences for more than 50 gallons a month. The Deputy-Controller of the department, however, on July 31st promised the British Medical Association that the department would consider any case in which a practitioner could prove conclusively that 50 gallons a month would be inadequate for his work. The Association subsequently laid before the department the particulars of several cases in which it was obvious that the practitioners concerned could not carry out their work on an expenditure of only 50 gallons a month, and in reply was informed by the Deputy-Controller that the question of the issue of supplementary licences in these cases would receive careful consideration. The Association is now informed that the Controller of the department is not in a position to increase the quantity at present beyond the 50 gallons a month already allotted to each of these doctors. As it is essential that practitioners, the majority of whom are at present doing work greatly in excess of that of pre-war times, shall if possible obtain adequate supplies, the Association is taking further steps.

Repair of Doctors' Cars.

The following letter, which explains itself, has been received by the Medical Secretary of the British Medical Association:

MINISTRY OF MUNITIONS OF WAR.
Priority Branch,
1, Caxton Street, Westminster, S.W.,
17th August, 1917.

Sir,
I am directed to acknowledge the receipt of your letter of the 13th August, and to refer to the interview which I had with you this morning with respect to the difficulty which medical practitioners sometimes experience in getting their motor cars repaired.

I think it is clear as the result of our conversation that the difficulty is for the most part not experienced in obtaining a certificate, but in getting the work done once the certificate has been obtained. I am afraid that, owing to the urgent war work on which not a few of the motor car manufacturers of this country are at the present time exclusively engaged, difficulties must continue to occur in the future in the case of certain makes of car.

It is clear, however, that in certain cases the maintenance and running repairs to doctors' cars are of equal importance with direct war work. Of these cases the British Medical Association is the best judge. If, therefore, in any case the British Medical Association will take the responsibility of stating that a repair is of urgent importance this department will be quite willing to issue a Priority 4 Certificate instructing all firms concerned that this particular repair is to be executed as war work. Even so, in the case of certain firms it is to be regretted that they will in all probability be unable to execute orders for spare parts with any reasonable promptitude, owing to the exceedingly urgent nature of the work on which they are engaged.

In the case of spare parts required for Ford cars, I am

informed that instructions have been sent to the Ford Company to release such parts to doctors without the necessity of applying for a certificate.

I am, Sir, your obedient servant,
W. T. SWAN SONNENSCHN
(For Deputy-Controller, Priority Department).

In acknowledging this letter Dr. Cox stated that the British Medical Association would be glad to take the responsibility in suitable cases submitted to it of reporting to the Priority Department that a repair is of such urgent importance that the department would be justified in issuing a Priority 4 Certificate.

Association Notices.

BRANCH AND DIVISION MEETINGS TO BE HELD.

NORTH OF ENGLAND BRANCH.—Dr. James Don, Honorary Secretary (1, Grove Street, Newcastle-on-Tyne), gives notice that the annual meeting of the North of England Branch will be held at 23, Ridley Place, Newcastle-on-Tyne, on Friday, September 7th, at 3.15 p.m.

INSURANCE NOTES.

COMPULSORY HEALTH INSURANCE: AN AMERICAN VIEW.

A PAMPHLET entitled, *Facts and Fallacies of Compulsory Health Insurance*, by Dr. Frederick J. Hoffman, issued by the Prudential Insurance Company of America, can only be regarded as a strong attack on the movement in America in favour of compulsory health insurance. To begin with, Dr. Hoffman says that compulsory health insurance is not in fact an insurance, but essentially an arbitrary taxation providing for an inequitable distribution of cost in the proportion of 40 per cent. contribution by wage earners, 40 per cent. by employers, and 20 per cent. by taxpayers at large, and that on any such basis it is only poor relief under another name. He then attempts to show that the degree of poverty in America is not of such serious importance as to require what he calls the "paternalistic form of government" of Germany. Strong criticism is directed against exaggerated statements about the physical deterioration in America, where the death-rate is so low (about 13.5 per 1,000) that there is no need, in the author's opinion, for such special remedies as compulsory health insurance. The whole movement in favour of it is treated as a propaganda for State socialism and class legislation, and it is stated that numerous medical societies have passed resolutions of disapproval. An attempt is then made to show that insurance has been a failure in England, the author evidently depending largely on the report of the Fabian Research Department, of which Mr. Sidney Webb was chairman. In further support of his view, Dr. Hoffman states that "every week the BRITISH MEDICAL JOURNAL contains in a SUPPLEMENT an extended account of seemingly endless quarrels, dissensions and disputes concerning fees, allotments, prescriptions, reductions, settlements, etc.," and he says, "it is a safe conclusion that the economic status of the medical profession will not be improved under compulsory health insurance in America." Further quotations from English medical journals are given as showing the deplorable effects of national insurance on medical practice and in reducing the standard of medical treatment. A good deal is also made of the argument that sickness insurance offers a pecuniary inducement to malingering. It is stated that the amount

of sickness in America has been grossly exaggerated and that America compares very favourably with Germany in this respect in spite of the German insurance.

The author tells us that the American Federation of Labour opposes compulsory insurance as inimical to labour welfare and public policy. What may be necessary for persons near or below the poverty line is not necessarily desirable for those who are able to provide for their own medical and other needs, and we read, "the tragedy of the National Health Insurance in England is that it has not improved the condition of the poor, but that the benefits have accrued to those least urgently in need of pecuniary assistance and free medical treatment," as the vast multi-plied brought within the Act were already providing what was requisite for themselves. The insurance medical service in England is characterized as "intolerably incomplete, intolerably wasteful, and intolerably costly," and the author claims that far better results would be got by insurance on a voluntary basis. He sees a solution of the difficulties in a more intelligently conceived State medical service and more systematic and well-considered poor relief, with an improvement in institutional facilities for medical treatment irrespective of social or economic status. Other measures advocated are a reform of the abuses of medical charities, compensation for industrial or occupational diseases as well as for industrial accidents, greater co-operation for sanitary services, better facilities for education in personal and public hygiene, and specially an improvement in the numerous forms of voluntary insurance and thrift movements, with proper State supervision.

We do not know whether Dr. Hoffman's views will meet with any general support in America. His statement that insurance in England is a failure is certainly open to dispute. Even if it were admitted that the results have not reached expectations, it might still be argued that any such comparative failure arose from the insurance not going far enough, or from details in administration which experience will correct, and not from any defect necessarily inherent in compulsory health insurance.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty: Fleet Surgeon C. S. Woodright has been promoted to the rank of Deputy Surgeon-General. Fleet Surgeon A. I. Sheldon to the *Pembroke*; Staff Surgeon G. O. M. Dickenson, M.B., to Haslar Hospital Camp; Surgeon A. Fairley, M.B., to the *Victory*. Temporary Surgeons C. de C. W. Langdon to Portsmouth Dockyard, temporary; M. Vlasto to the *Victory*; J. R. W. Stephens to Plymouth Hospital; R. Silcock to Haslar Hospital; E. Bayley, M.D., to the *Hindustan*, vice Townley; H. McC. Bainschell, D.S.C., and G. W. Pratt, to Chatham Hospital; W. H. Kay, M.B., to the *Pembroke*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Probationer H. A. Potter to the *Contest*. Surgeon Probationer A. D. MacHaffie has been granted a temporary commission as dental surgeon, and appointed to the *Europa*. To be Surgeon Probationers: H. L. Sackett, A. J. De La O'Connor.

ARMY MEDICAL SERVICE.

Surgeon-General Sir T. P. Woodhouse, K.C.M.G., C.B., and Colonel R. J. Windle, M.B., are retained on the active list, and to be supernumerary.

Lieut.-Colonels to be temporary Colonels whilst employed as Assistant Directors of Medical Services: G. W. Tate, M.B., F. E. Gunter, M.B. (substituted for notification in the *London Gazette* of January 27th, 1917).

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel G. J. A. Ormsby, D.S.O., M.B., to be temporary Colonel whilst an Assistant Director of Medical Services of a Division. Major (temporary Lieut.-Colonel) E. McDonnell, D.S.O., M.B., to be an Assistant Director of Medical Services of a Division, and to retain his temporary rank whilst so employed.

Major R. B. Holt, M.B., and Major (Brevet Lieut.-Colonel) C. R. S. Bradley, to be acting Lieut.-Colonels whilst in command of a stationary hospital.

Majors W. J. Waters and J. M. H. Conway, D.S.O., F.R.C.S.I., to be acting Lieut.-Colonels whilst in command of a casualty clearing station.

Captain R. E. U. Newman, M.C., M.B., to be acting Lieut.-Colonel whilst in command of a field ambulance.

Temporary Captain A. W. Robertson to be temporary Major.

Temporary Lieutenants to be temporary Captains: H. H. R. Bayley, F. K. Campbell, M.B., F.R.C.S.

Officers relinquish their commissions: Temporary Captains D. Villisid (on account of ill health), R. V. McDonnell, M.C., F. J. Livingston, M.B., V. F. Stock; Temporary Lieutenant R. D. Ferguson, M.D.

To be temporary honorary Lieutenants: C. E. Allison, F. A. Simonds.

OVERSEAS CONTINGENTS.

CANADIAN ARMY MEDICAL SERVICE.

Deputy Assistant Director of Medical Services temporary Captain H. C. Messerian, C.A.M.C., relinquishes his appointment.

CANADIAN ARMY MEDICAL CORPS.

Temporary Major J. R. Spier to be temporary Lieut.-Colonel (substituted for the *London Gazette* notification July 27th incorrectly specifying name of "Speir").

Temporary Majors to be temporary Lieut.-Colonels: C. S. McVicar, W. J. O. Malloch.

Temporary Captains to be temporary Majors: S. G. Chown, H. E. Cumming.

Temporary Captains to be acting Majors, whilst specially employed: D. A. L. Graham, W. H. Lowry, R. G. Armour.

Temporary Lieutenant E. S. Jeffrey to be temporary Captain.

Temporary Quartermaster and honorary Captain J. W. White to be honorary Major whilst specially employed.

Sergeant-Major M. F. Millard to be temporary Quartermaster with the honorary rank of Lieutenant (substituted for *London Gazette* notification of July 19th incorrectly specifying initials as "F. M.").

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel H. W. Webber, F.R.C.S., is seconded for duty with a general hospital.

Temporary Lieut.-Colonel R. P. Jack, M.B., Scottish Rifles, T.F., to be temporary Lieut.-Colonel.

Major P. G. Williamson, M.C., M.B., to be acting Lieut.-Colonel whilst commanding a field ambulance.

Captain (acting Lieut.-Colonel) R. W. Brimacombe to be Major and acting Lieut.-Colonel.

Captain J. W. Mackenzie, M.D., to be Major.

Captain (temporary Major) E. M. Jenkins, M.B., relinquishes his temporary rank on ceasing to command a field ambulance.

Captain J. G. Emanuel, M.D., is seconded for duty with a general hospital.

The Christian names of Captain Philip Halbert Green, M.B., are as now stated and not as announced in the *London Gazette* of August 21st.

Captains S. G. Webb, M.D., and J. Gilchrist, M.D., are restored to the establishment.

VACANCIES.

NOTICES REGARDING APPOINTMENTS.—Attention is called to a Notice (see Index to Advertisements—Important Notice re appointments) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

AYRSHIRE: COLMONELL PARISH.—Medical Officer for the Lower District. Salary, £70 per annum; vaccination salary, £2.

BRISTOL ROYAL INFIRMARY.—(1) House-Physician; (2) House-Surgeon. Salary, £120 per annum.

BURSLER: HAYWOOD HOSPITAL.—Resident Medical Officer (female). Salary, £300 per annum.

BURY INFIRMARY.—Junior House-Surgeon. Salary, £150 per annum.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—House-Physician. Salary, £150 per annum.

COVENTRY EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary, £350 per annum.

DEVON COUNTY EDUCATION COMMITTEE, Exeter.—Temporary Oculist. Salary, £8 8s. per week.

EASTBOURNE EYE INFIRMARY.—Ophthalmic Surgeon.

CURRENT NOTES.

The Army Medical Service Inquiry.

At its meeting on August 29th the Central Medical War Committee resolved to represent to the Government that, in view of the composition of the Committee of Inquiry (the only intimation of which it had received through the public press), it is emphatically of opinion that unless at least the Chairman of the Central Medical War Committee is added thereto the personnel of the new Committee will not satisfy the opinion of the general body of medical practitioners in this country.

Medical Recruiting Boards.

In a communication from the Secretary of the Select Committee on the Military Service (Review of Exceptions) Act to the Central Medical War Committee, it was stated that the Select Committee would probable hear no further evidence until after the recess, and that it had not decided on the procedure for the next session. In the meantime it asked whether the Central Medical War Committee desired to present a memorandum or witnesses. From this it is to be gathered that the Select Committee has not completed its inquiry, which will come as something of a shock to many people who hoped that this body would soon issue its report and then cease from troubling.

Petrol for Medical Practitioners.

In last week's SUPPLEMENT we referred again to the supply of petrol to medical practitioners for use in professional work, and to the representations made by the British Medical Association to the Petrol Control Department for the issue of supplementary licences for doctors who could not carry out their work on an allowance of 50 gallons a month. The Association was informed that the Controller of the department was not in a position to allow an increase in any of the cases submitted by the Association. In view of the serious effect of this refusal, the Deputy Medical Secretary addressed a letter on August 22nd to the President of the Board of Trade, pointing out that a strict limitation to a maximum of 50 gallons a month without regard to special circumstances would force certain practitioners to give up a considerable portion of their work, with the result that some sections of the community would have to go without medical attendance altogether. The letter went on to say that the Association fully realizes the seriousness of the petrol situation, and is doing all in its power to secure that doctors shall exercise the utmost care in the use of petrol; but in view of the importance of maintaining an efficient medical service for the civil community it urges the Board of Trade to authorize the issue of a supplementary licence to those doctors who can prove that the restriction to 50 gallons a month will prevent them from fulfilling their duties to the public. The President of the Board of Trade has replied that the Controller of Petrol Supplies has now further considered the matter. While of opinion that the maximum

of 50 gallons should, generally speaking, suffice for the absolutely necessary use of a motor car for professional purposes, the Controller recognizes that the medical profession is working under very great pressure at the present time, and that many doctors are doing double duty, and he is now prepared, where the need for more than 50 gallons of petrol is exceptional, to give a special licence in excess of that amount. Every effort must be made to limit such applications, as the fixed maximum can only be exceeded in cases of the utmost necessity. This concession is important, and will be appreciated by the medical profession and by the public which it serves.

Shortage of Rubber Operating Gloves.

The prohibition by the Board of Trade of the importation of rubber operating gloves was referred to in the JOURNAL of August 18th, p. 228, and the serious effect of such action upon civilian surgical practice was pointed out. As already announced, the British Medical Association has taken up the matter with the Board of Trade with a view to permission being granted for the importation of adequate supplies for the needs of the civil community. In the meantime the Association has received a communication from the secretary of the Rubber and Tin Exports Committee, from which it appears that applications for licences to export rubber gloves are of frequent occurrence. In dealing with such applications the prime consideration has been to deprive the enemy of any chance of obtaining supplies, and licences have been granted only when the destination of the goods was considered safe. In view of the information which we published, the Committee suggests that the shortage at home might perhaps be relieved in some measure by a closer restriction of export licences, even to the extent of total suspension, except for allied destinations. The curious position is thus revealed that while the Board of Trade on the one hand was proceeding to produce a shortage of rubber gloves by stopping their importation, another Government authority was granting licences for the export of such gloves in ignorance of their scarcity in this country. The Deputy Medical Secretary of the British Medical Association has replied to the Rubber and Tin Exports Committee, stating that the Association is informed that surgical gloves cannot be made in sufficient numbers in this country for present requirements, and will shortly be unobtainable for operations on civilians; that the Association has urged the Board of Trade to allow adequate imports, and trusts that the Rubber and Tin Exports Committee will at once consider the advisability of exercising the closest restriction on export licences, even to the extent of their total suspension. We hope that the situation will soon be relieved now that the official inlet and outlet are both aware of the danger.

Association Notices.

BRANCH AND DIVISION MEETINGS TO BE HELD.

NORTH OF ENGLAND BRANCH.—Dr. James Don, Honorary Secretary (1, Grove Street, Newcastle-on-Tyne), gives notice that the annual meeting of the North of England Branch will be held at 23, Ridley Place, Newcastle-on-Tyne, on Friday, September 7th, at 3.15 p.m.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following notifications are announced by the Admiralty: Fleet Surgeon R. Miller, M.B., is placed on the retired list at his own request, with the rank of Deputy Surgeon-General. Fleet Surgeons M. P. Jones, J. D. Milligan, M.B., and A. W. Walker to the *Frigate*, additional; E. A. Shaw, M.D. (retired), to the *Victory*, additional; R. W. Townley, F.R.C.S., to the *Pembroke*, additional. Staff Surgeons W. N. Blackford to the *Frigate*; J. H. Wright, M.B., to Chatham Dockyard; Surgeon S. L. McBean, M.B., to the *Victory*. Temporary Surgeons A. W. Gunn, M.D., and D. S. MacKnight, M.B., to the *Pembroke*; C. H. Gould to the *Research* for Portland Hospital; F. A. Knott to the *Achilles*; W. F. Jones to the *Harrier*; M. Fawkes, M.B., to the *Euroda*; A. McMillan to the *Pembroke*, additional. To be temporary Surgeon: K. R. Hill.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon probationer G. Burnett to the *Legion*. To be Surgeon probationer: M. D. Cadman, R. L. Dodds.

ARMY MEDICAL SERVICE.

Colonel F. W. C. Jones, C.B., M.B., is retained on the active list and to be supernumerary.

Captain W. C. Smales, D.S.O., R.A.M.C., to be Deputy Assistant Director-General.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel (temporary Colonel) P. Evans, C.M.G., M.B., relinquishes his temporary rank on reposting.

Officers granted temporary rank as stated:—As Lieut.-Colonels: Lieut.-Colonels F. H. Maturin (Hampshire Regiment) and J. F. Haswell, M.D. (Border Regiment). Temporary Lieut.-Colonel F. R. Hill, M.B. (R.F.A.). As Majors: Majors F. R. S. Cosens (Devon Regiment), T. B. Higgs, M.D. (East Kent Regiment).

Major W. C. Croly and Captain J. L. Wood relinquish the acting rank of Lieut.-Colonel on reposting.

To be acting Lieut.-Colonels: Major T. E. Fielding, D.S.O., M.B., and temporary Major H. H. Serpell whilst in command of a general hospital; Major E. W. Sibery whilst in command of a casualty clearing station; Captain H. G. Monteith, D.S.O., whilst in command of a field ambulance.

Temporary Captain C. S. Miller, M.B., relinquishes his commission, and is granted the honorary rank of Captain.

Temporary Captain J. H. Patterson relinquishes his commission.

Temporary Lieutenants to be temporary Captains: C. G. McAdam, M.B., H. Harrison, G. H. U. Corbett, M.B., A. B. Moffat, M.B., H. O'Neill, M.B.

Temporary Lieutenant J. Young relinquishes his commission.

H. F. Bold-Williams, M.B., to be temporary honorary Lieutenant whilst doing duty with No. 8 Red Cross (Baltic and Corn Exchange) Hospital.

To be temporary honorary Lieutenants: M. C. Pruitt, R. G. Carothers, J. F. Harvey, C. K. Valade.

INDIAN MEDICAL SERVICE.

Brevet Colonel Sir B. G. Seton, Bt., has been permitted to retire from the service with effect from May 27th, 1917.

Major J. M. Holmes, appointed to be a Deputy Assistant Director, Medical Services, with effect from March 29th, 1917.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Major J. Clarke to be acting Lieut.-Colonel whilst in command of a stationery hospital.

Captain A. G. W. Compton, M.C., relinquishes his commission on account of ill health.

Captain A. T. Pitts, from R.A.M.C.(T.F.), to be Captain, with seniority next below Captain W. J. S. Ingram, M.C., M.B.

Lieutenants to be Captains: D. Stewart, L. P. Johns.

To be Lieutenants: J. W. Bowman, M.B., C. A. Harvey, M.B., and G. F. Mitchell, M.B., from Aberdeen University Contingent O.T.C.;

J. Irvine, M.B., J. Kinnear, M.B., and F. J. Charlton, M.B., from St. Andrews University Contingent O.T.C.;

D. J. Valentine, S. W. Page, C. M. Titterton, and E. H. Glenny from University of London Contingent O.T.C.;

H. B. Dykes, M.B., from Edinburgh University Contingent O.T.C.;

G. K. Fulton, M.B., W. Adams, M.B., R. Aitken, M.B., T. Fleming, M.B., J. S. Martin, M.B., N. MacKillop, M.B., W. Dempster, M.B., E. P. Irving, M.B., J. H. Shearer, M.B., W. McWilliam, M.B., J. Ashforth, M.B., and J. S. Craig, M.B., from Glasgow University Contingent O.T.C.;

H. E. Charles, M.B., C. H. Smith, M.B., P. Shillito, M.B., N. Pick, M.B., G. F. Hurst, M.B., H. V. Horsfall, J. H. Parker, M.B., S. Adler, M.B., from Leeds University Contingent O.T.C.;

T. J. Shaw, P. V. Anderson, M.B., H. J. Rice, M.B.

TERRITORIAL FORCE.

ARMY MEDICAL SERVICE.

Colonel J. B. Mann relinquishes his commission on account of ill health, and is granted permission to retain his rank and wear the prescribed uniform.

Lieut.-Colonel R. Pickard, C.M.G., M.D., to be Assistant Director of Medical Services, and to be temporary Colonel whilst so employed.

Captain H. M. Calder, D.S.O., M.B., to be Deputy Assistant Director of Medical Services.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel R. Pickard, C.M.G., M.D., is seconded whilst holding an appointment as Assistant Director of Medical Services.

Major W. D. Watson to be acting Lieut.-Colonel whilst commanding a field ambulance.

Major (acting Lieut.-Colonel) W. A. Burns, M.B., relinquishes his acting rank on ceasing to command a field ambulance.

Captain (acting Lieut.-Colonel) J. Blackwood relinquishes his acting rank on ceasing to command a field ambulance.

Major C. J. Martin, M.B., from A.M.S., to be Major.

Captain H. M. Calder, D.S.O., M.B., is seconded whilst holding an appointment as Deputy Assistant Director of Medical Services.

Captains F. J. Stansfield and R. Mitchell are restored to the establishment.

Captain A. R. Short, M.D., is seconded for duty with a casualty clearing station.

Lieutenant W. Brander, M.D., to be Captain, with precedence as from March 31st, 1915.

Private J. W. Munro to be Lieutenant.

VACANCIES.

NOTICES REGARDING APPOINTMENTS.—Attention is called to a Notice (see Index to Advertisements—Important Notice re Appointments) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

ANCOATS HOSPITAL, Manchester.—Honorary Physician to Skin Department. Remuneration, 3 guineas per clinic.

AYRSHIRE: COLMONEILL PARISH.—Medical Officer for the Lower District. Salary, £70 per annum; vaccination salary, £2.

BECKETT HOSPITAL, Barnsley.—Second Lady House-Surgeon. Salary, £200 per annum.

BIRKENHEAD UNION.—Junior Female Resident Assistant Medical Officer. Salary, £300 per annum.

BOLTON INFIRMARY.—Lady Locumtenent as Assistant Surgeon.

BOROUGH OF MANFIELD.—Medical Officer of Health and School Medical Officer (temporary). Salary, £500 per annum.

BRISTOL ROYAL INFIRMARY.—(1) House-Physician; (2) House-Surgeon. Salary, £120 per annum.

BURY INFIRMARY.—Junior House-Surgeon. Salary, £150 per annum.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL.—House-Physician. Salary, £150 per annum.

CHELTEMHAM EYE, EAR, AND THROAT FREE HOSPITAL.—Honorary Surgeon.

CUMBERLAND COUNTY.—Lady Assistant Medical Officer. Salary, £350 per annum.

DERRYSHIRE ROYAL INFIRMARY.—House-Surgeon. Salary, £200 per annum.

DEVON COUNTY EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary, £8 8s. per week.

CURRENT NOTES.

The Army Medical Service Inquiry.

WITH reference to the resolution passed on August 29th by the Central Medical War Committee, and reported in this column last week, we have received the following statement from the Vice-Chairman of the Committee:

The Central Medical War Committee desired that its Chairman should be added to the Committee of Inquiry proceeding to France, but Lord Derby has expressed "his regret that it is impossible to make any alteration in the constitution of the Committee." He adds that "the Committee was very carefully chosen, and is one to investigate matters purely for the information of the Secretary of State in the interests of the army." But the Central Medical War Committee, in the course of its long and arduous work to obtain the maximum of medical officers for the army with due consideration for civil needs and for the interests of doctors concerned, has been greatly troubled by views widely spread and freely expressed that economy in the use of men could reduce the number required. To ascertain if there were ground for this impression, and to consider how best civil and military medical organization could progress side by side and, where advisable, dovetail the one into the other: these were generally understood to be the objects of the inquiry. It was in this belief that the Central Medical War Committee hoped it might be consulted as to the personnel of the Committee of Inquiry; and not from any want of satisfaction with those actually appointed to serve did it suggest an additional member, but from a strong conviction that something more was required—the representation of other elements of professional opinion. This, it considered, its chairman would furnish, and that, from his experience of professional organization and acquaintance with practitioners in all kinds of practice, he would help materially in the work.

E. B. TURNER,

Chairman of Representative Body, British Medical Association; Vice-Chairman Central Medical War Committee.

Shortage of Rubber Operating Gloves.

In the JOURNAL of August 18th and in the SUPPLEMENT of September 1st we referred to the threatened shortage of rubber operating gloves and to the steps taken by the British Medical Association in order to secure adequate supplies for the needs of the civil community. We have now to record that the Deputy Controller of the Department of Import Restrictions of the Board of Trade has informed the Association that the concession which is

being arranged in regard to manufactures of rubber will include rubber gloves, and that the matter is being dealt with on behalf of importers in this country by the American Chamber of Commerce. Communication was therefore opened up with the American Chamber of Commerce, which was informed of the position, so far as this is known to the Association, and invited to furnish information. It appears that the Board of Trade has decided to restrict the importation of all manufactured rubber goods for 1917 on the basis of 15 per cent. of last year's imports. The secretary of the Chamber makes two suggestions to meet the urgent need for rubber operating gloves: all importers of manufactured rubber articles might confine their imports to surgical gloves; or as an alternative, general importers of manufactured rubber goods might allow the firms who are actual importers of surgical gloves a part or the whole of their 15 per cent. ration of the 1916 imports. It would seem, therefore, that the situation is now in the hands of the firms which import rubber articles within the terms of the concession granted by the Board of Trade. We hope they will appreciate the need for securing a sufficient supply of surgical gloves for civilian purposes and will at once make arrangements among themselves to this end.

Meetings of Branches and Divisions.

SOUTHERN BRANCH.

THE annual meeting of the Branch was held at the South-Western Hotel, Southampton, on July 12th, when Dr. A. E. BODINGTON (Winchester) was in the chair, and twelve other members were present.

Election of Officers.—No nominations having been received other than those of the Branch Council these became valid.

Balance Sheet.—The balance sheet and annual report were presented and adopted.

Quorum.—The CHAIRMAN moved a resolution, which was unanimously carried, that the future quorum of the Branch Council consist of five members.

Branch President.—Dr. BODINGTON, in his valedictory address, strongly advocated the claims of the Association on the support of the profession, and pointed out how adequately it met the needs of the members. He then introduced Dr. H. J. May, of Southampton, as the president for the ensuing year. Dr. MAY thanked the members for their cordial reception, and promised to do his best to justify their confidence; he moved a vote of thanks to Dr. Bodington, which was carried by acclamation. There was no luncheon on account of the war and no golf competition. By the kindness of the President tea was served at the close of the meeting. A collection for Epsom College realised £2 10s. 6d.

British Medical Association.

CURRENT NOTES.

Discharged Disabled Sailors and Soldiers: Regulations for Medical Treatment.

THE National Health Insurance Commissioners have now issued new regulations making special arrangements for the medical treatment by general practitioners of all sailors and soldiers invalided from the Forces. These regulations are in fulfilment of the arrangement entered into between the Commissioners and the British Medical Association, and reported in the Supplementary Report of Council as well as in a document issued to all Panel Committees. In an explanatory note it is pointed out that the new system has been instituted as an emergency measure "to meet representations made to the Commissioners on behalf of the medical profession that the normal system of remuneration would be inequitable as applied to invalided sailors and soldiers under the present abnormal conditions of war." The arrangements set forth in these regulations are experimental, and subject to reconsideration at any time. In a circular sent on September 1st to Local Medical and Panel Committees, and to Divisions and Branches of the British Medical Association, announcing the issue of the new regulations, the Medical Secretary stated that the Insurance Acts Committee, in view of the fact that the regulations merely carry out the agreement entered into, advises that insurance practitioners in each area be recommended to accept the arrangement. The circular ends with a reminder that although the regulations do not refer to the undertaking by the Treasury to make good any excess of practitioners' accounts over the total of the pool formed by the 9s. per head at present available under the Insurance Acts, the proposals of the Commissioners to the Insurance Acts Committee (SUPPLEMENT, June 16th, 1917, p. 139) stated specifically that "if the total payments to be made are in excess of a sum calculated at the rate of 9s. per discharged disabled man the amount of the excess will be found by the Exchequer." Attention may be drawn here to the letter printed this week in the body of the JOURNAL (p. 373), from the Chairman of the Insurance Acts Committee, dealing with recent criticisms of the action taken by the Association.

Cost of Petrol.

In consequence of numerous complaints from medical practitioners in all parts of the country respecting the recent very great advance in the price of petrol, the British

Medical Association has made representations to the Petrol Control Department, pointing out that if the present charges are continued medical attendance on the civil community will be seriously curtailed, and it will be impossible for practitioners to carry on much of the work which they are doing on behalf of absent colleagues and at military and auxiliary hospitals. The Department has been urged, in view of the serious position that now exists, to intervene in the matter, and if necessary to provide that medical practitioners be supplied with petrol for their professional work at Government rates.

SHORTAGE OF MEDICAL STUDENTS.

MEMORANDUM BY THE COMMITTEE OF REFERENCE.

At the meeting of the Central Medical War Committee on September 12th a communication was received from the Secretary of the Committee of Reference reporting that the following memorandum, dated August 30th, 1917, had been adopted and forwarded to the Prime Minister, the Secretary of State for War, the Minister of National Service, the Adjutant-General, and Sir Alfred Keogh:

1. The Committee of Reference feel it their duty to call the serious attention of His Majesty's Government to the certainty that, owing to the enlistment of medical students as combatants in the years 1914 and 1915, the numbers of doctors to become qualified in the near future must fall short of the requirements of the nation, unless immediate steps are taken to meet the situation.

2. From the returns which have been supplied to the General Medical Council, it was shown that at the beginning of the year 1916 there were in the medical schools the following students:

Entered as Students in	Therefore in 1916	Men.	Women.	Total.	Eligible to Qualify in
1915	1st year	1422	636	2058	1921
1914	2nd year	783	295	1078	1920
1913	3rd year	519	163	682	1919
1912	4th year	1078	145	1223	1918
1911	5th year	922	140	1062	1917

3. Since the Government has decided that fourth and fifth years' students who can possibly qualify in two years may continue or resume their medical studies, the supply of doctors for 1917 and for 1918 may be considered as fairly assured, so far as to fill the gaps in the profession caused by the usual losses by death and retirement, but it cannot be said that the losses brought about by casualties in the field will be made good, nor does it provide for any increase that may be required for the R.A.M.C.

4. From the figures given in the above return the students of both sexes in their second and third years, who should qualify in 1919 and 1920, are considerably less than those who should qualify in 1917 and 1918. They are 1,302 males as against 2,000; males and females together 1,760 against 2,285.

5. So far as males are concerned, these figures represent a number considerably in excess of those who can possibly qualify in 1919 and 1920, for a large proportion of them have either voluntarily joined, or have been called up under the Military Service Act into the combatant ranks.

6. The large number in the first year, that is, those who should qualify in 1921, is entirely misleading, because a large proportion of these male students are under 18 years of age, and are therefore called up to join the army as soon as they reach the age of military service.

7. Whilst there is likely to be an increase in the number of qualified women doctors in the near future, it should be pointed out that they are not suitable for all hospital appointments, nor for all forms of general practice, and of course are not available for the navy and army. It must, therefore, not be assumed that an increase of women doctors can compensate for a serious shortage of male doctors.

8. The only conclusion that can be drawn from the above is that the outlook for the maintenance of the numbers of qualified doctors after the year 1918 is extremely serious, for the needs of the civil population as well as of the navy and of the army.

9. The Committee of Reference would draw the attention of His Majesty's Government to the hardships inflicted by the present arrangement on the medical student who enlisted or took a commission before the Military Service Act, compared with his fellow student who did not enlist, and is therefore a fourth or fifth years' student. The former has had to defer, in many instances by three years, the earliest date of his qualification, whereas the latter has been allowed to continue his medical studies until qualified. The Committee would therefore suggest that it is only fair to those whose patriotism led them to enlist in the early days of the war, that they should be allowed to return to their medical studies.

10. The Committee of Reference, in consequence of these facts, earnestly desire to impress upon His Majesty's Government the necessity of taking immediate steps to meet this shortage, and they recommend:

(a) That medical students now serving in the army, whether as officers or privates, who have already passed the examination in anatomy and physiology for a medical qualification, should be demobilized and returned to their medical schools to complete their studies.

(b) That medical students, now serving in the army, whether as officers or privates, who have not passed the examination in anatomy and physiology, should be seconded to their medical schools for a reasonable period to enable them to pass that examination, and that if successful they should be demobilized to complete their studies.

11. It is, in the opinion of the Committee, highly desirable that effect should be given to these recommendations as soon as possible.

August 30th, 1917.

FREDERICK TAYLOR, M.D.,
Chairman.

The Central Medical War Committee, after consideration of the above memorandum, passed the following resolutions:

1. That, in the opinion of this Committee, it is desirable that all medical students who are registered as such in the books of the General Medical Council, or, in case of doubt, present a certificate from the dean of their medical school, now serving with the navy or army as officers or privates, should be demobilized to continue their studies.
2. That, in the opinion of this Committee, the calling up of more medical students who are registered as such in the books of the General Medical Council, or, in case of doubt, present a certificate from the dean of their medical school, and who have completed their first year of study, should cease.

It was decided that these recommendations, together with a covering letter pointing out that the deficiency in the numbers of first, second, and third year students is much greater than appears from the table given above, should be forwarded to the Prime Minister, the Minister of National Service, the Adjutant-General, the Director-General of the Army Medical Department, and the President of the Board of Education.

Meetings of Branches and Divisions.

KENT BRANCH: BROMLEY DIVISION.

The following officers have been elected for 1917-18:

Chairman: Dr. Bailey. Vice-Chairman: Dr. Crombie.
Joint Honorary Secretaries: Drs. A. Tennyson Smith and W. H. Chesters.
Representative for Representative Meetings: Dr. A. Tennyson Smith. Deputy Representative: Dr. G. R. Stilwell.
Representative on Branch Council: Dr. Lewis.

Executive Committee: Drs. H. W. Henshaw, J. F. Douse, C. E. M. Lewis, C. E. Michael, T. D. Miller, E. G. Pringle, G. R. Stilwell, W. F. Umney, J. H. Yolland.

NORTHERN COUNTIES OF SCOTLAND BRANCH: ROSS AND CROMARTY DIVISION.

At a meeting of the Ross and Cromarty Division, held in the Ross Memorial Hospital, Dingwall, on August 13th, the following officers were elected for 1917-1918:

Chairman: Dr. John Broadfoot (Dingwall). Vice-Chairman: Dr. John Cameron (Forriose).

Honorary Secretary: Dr. E. K. Mackenzie (Tain).

Representative for Representative Meeting: Dr. J. Monro Moir (Inverness).

Representative on Branch Council: Dr. J. Pender Smith (Dingwall).

Executive Committee: Drs. John Cameron, W. W. N. Knox, D. Johnston, Hugh Ross, J. P. Smith, J. A. Somerville.

The following resolutions were adopted:

1. Fees for Attendance upon Private Patients.—For patients living within one mile of the doctor's surgery fees should be increased by 25 per cent., while for patients living outside this area fees for attendance should be increased by 35 per cent.

2. Treatment of Widows and Families of Soldiers and Sailors.—No medical man practising within the area of the Division should enter into any contract with any public body for attendance upon or treatment of the widows and families of soldiers and sailors without first consulting the members of the Division at a meeting of which due notice had been given to each member.

NORTH OF ENGLAND BRANCH.

The annual meeting of the North of England Branch was held at Newcastle-upon-Tyne on September 7th, with the retiring President, Mr. A. E. MORRISON, in the chair.

Most of the business was of a routine nature, yet there was a large attendance, which undoubtedly would have been larger still but for the strenuous times in which medical men are now living. Since the beginning of the war the delivery of a Presidential Address by the incoming President has been suspended, but it is hoped that the practice will be revived when more normal circumstances prevail.

Election of Officers.—The following officers were elected for the ensuing year:

President: Dr. J. W. Smith (Ryton).

President-elect: Dr. R. E. Howell (Middlesbrough).

Vice-Presidents: Drs. J. Charles (Stanley), J. Hudson (Newcastle-upon-Tyne).

Honorary Secretary and Treasurer: Dr. J. Don (Newcastle).

Honorary Scientific Secretary: Dr. R. J. Willan (Newcastle).

NORTH OF ENGLAND BRANCH: SOUTH SHIELDS DIVISION.

The following officers have been elected for 1917-18:

Chairman: Dr. G. W. Weir. Vice-Chairman: Dr. M. D. Mathieson.

Honorary Secretaries: Drs. T. O'Callaghan and J. Macdonald.

Representative for Representative Meetings: Dr. A. Martin (North Shields). Deputy Representative: Dr. G. R. Harland (South Shields).

Representatives on Branch Council: Drs. Harland and Mathieson.

Executive Committee: Drs. J. L. Crisp, Gibbon, Harland, Marks, Ord, Overill, Sinclair, Turner, and Whyte.

SOUTH WALES AND MONMOUTHSHIRE BRANCH: SOUTH-WEST WALES DIVISION.

At the last annual meeting of this Division (comprising the counties of Cardigan, Carmarthen, and Pembroke) the following officers were elected:

Chairman: Dr. Lewis Williams (Ferryside). Vice-Chairman:

Dr. C. D. Mathias (on active service), re-elected.

Secretary and Treasurer: Dr. D. R. Price, re-elected.

Representative: Dr. Richard Hopkin. Deputy Representative:

Dr. J. E. P. Davies.

The committees were all re-elected, Dr. Samuel Williams taking the place of the late Dr. Harry Roberts on the Executive and Branch Council. A unanimous vote of thanks was given to Dr. Joshua Powell for the able manner in which he carried out the duties of the chair during his year of office.

INSURANCE.

LOCAL MEDICAL AND PANEL COMMITTEES.

BIRMINGHAM.

At a meeting of the Birmingham Panel Committee on September 4th a scheme suggested by the Insurance Committee for the scrutiny of prescriptions was agreed to, and it was decided to ask that a copy of the latest tariff be sent to all practitioners on the panel as soon as convenient.

It was decided to recommend panel practitioners in the area to accept the new regulations with regard to the treatment of discharged disabled soldiers and sailors.

After consideration of a letter from the Chairman of the Gloucester Panel Committee on the same subject, it was decided that the Government terms were quite fair and worthy of a trial, and better than those suggested by the Gloucester Panel Committee.

It was decided to inform the London Panel Committee that the advice of the British Medical Association would be followed with regard to the circular issued by the London Panel Committee suggesting the formation of an Association of Panel Committees.

NOTTINGHAMSHIRE.

At a meeting of the Notts Local Medical and Panel Committees on August 31st a complaint against a practitioner on the panel for charging a fee to an insured patient for taking out a thorn from and cauterizing his eye was considered. It was resolved to report that no evidence had been submitted that any treatment given was beyond the scope of work which could consistently with the best interests of the patient be properly undertaken by a general practitioner of ordinary competence and skill.

On consideration of a letter from the pricing bureau stating that errors were likely to occur in the pricing by reason of there being several different local formularies in use, it was agreed that instructions should be given that when short titles were used they should be held to refer only to those of the B.P., the B.P.C., and the official Notts formulary.

WEST RIDING OF YORKSHIRE.

At a meeting of the West Riding Local Medical and Panel Committees on July 6th it was reported that the Commissioners had extended the term of office of the Committee for one year from July 14th, 1917.

It was decided to allow the interim report on Insurance Acts Reconstruction of the York Local Medical and Panel Committee to lie on the table.

A letter was read from the Insurance Committee stating that it was prepared to accept the suggestion of the Panel Committee that the scheme for the supply of dressings and appliances should come into operation as and from April 1st, 1917.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty:—Temporary Surgeons: J. Hollings to the *Penbrooke*, additional, for Chatham Hospital; W. M. Fairlee, M.D., to Gibraltar Hospital; W. G. Bigger, M.B., to the *Victory*; C. J. A. McKillop, M.B., and W. S. Kidd, M.B., to Haslar Hospital; J. Morrison, M.B., to the *Bacchante*; R. J. Monahan, M.D., to the *King Alfred*; E. F. Fisher, M.B., F.R.C.S., to Queensferry Hospital; H. E. Cockcroft to Plymouth Hospital; A. G. Brett to the *Albion*.

ROYAL NAVAL VOLUNTEER RESERVE.

To be Surgeon Probationers: E. R. Jagers, H. V. Phelon, L. C. Verity, E. N. D. Reppe, J. D. Kinsman.

ARMY MEDICAL SERVICE.

Colonel (temporary Surgeon-General) G. D. Hunter, C.B., C.M.G., D.S.O., is retained on the active list and to be supernumerary. Colonel H. A. Thompson, C.M.G., D.S.O., M.B., to be temporary Surgeon-General whilst employed as Director of Medical Services. Lieutenant-Colonel and Brevet Colonel S. L. Cummins, C.M.G., M.D., to be temporary Colonel whilst employed as Assistant Director of Medical Services of a Division. Lieutenant-Colonel S. P. St. D. Green, M.D., to be temporary Colonel whilst employed as Assistant Director of Medical Services of a base.

ROYAL ARMY MEDICAL CORPS.

The surname of temporary Captain T. C. Harte is as now described, and not "Harke," as in the *London Gazette* of December 23rd, 1915.

Temporary Lieutenant H. R. Marsh relinquishes his commission.

The name of temporary Captain W. G. L. Wambeck is as now described, and not as in the *London Gazette* of July 10th, 1915, and July 4th, 1916.

The name of temporary Lieutenant N. B. Stewart, M.B., is as now described, and not as in the *London Gazette* of March 10th. Lieutenant-Colonel A. J. Coxis, M.D., Cyclist Battalion T.F., to be temporary Lieutenant-Colonel.

C. T. Parsons, M.D., to be temporary Lieutenant-Colonel whilst employed at the Fulham War Hospital, July 16th, 1917 (substituted for notification in the *London Gazette* of August 3rd, 1917).

To be acting Lieut.-Colonels: Major W. L. Baker and Captain O. C. P. Cooke whilst in command of a casualty clearing station: Major W. F. Ellis and Captains H. W. Carson, M.B., and E. C. Lambkin, M.B., whilst in command of a field ambulance.

The undermentioned are granted temporary rank as stated (substituted for notification in the *London Gazette* of August 8th, 1917): As Lieut.-Colonel: Lieut.-Colonel J. Godding, London Regiment T.F.; as Major: Major W. E. M. Corbett, Devon Regiment T.F.

Temporary Major R. S. Rodger, M.B., relinquishes his commission, and is granted the honorary rank of Major.

Temporary Major J. McC. Martin, D.S.O., relinquishes his commission.

Temporary Captain O. Challis to be temporary Major.

T. E. K. Stansfield, M.B., to be temporary honorary Major.

Captain C. Helm, M.C., relinquishes the acting rank of Lieut.-Colonel on reposting.

The following relinquish their commissions on account of ill health: Temporary Captains R. J. Cane, C. G. Galpin, M.B., M. C. Bridgman, M.D., J. G. Dick, M.B., J. H. N. F. Sary, M.B. Temporary Lieutenants W. T. Warwick, L. E. Fannin.

Temporary Captains relinquish their commissions: W. J. M. Marcy, R. W. Young, M.B., A. T. Bond, M.B., P. Verdon, C. A. Verge, M.B., V. D. Desrosiers, M.D., P. Quesnal, M.D., C. E. Tucker, M.B., A. W. Pretherton, M.B., W. W. Patton, M.D., N. Tattersall, M.B., H. L. Dixon, M.D., W. Elwood, M.B., S. J. Staples, M.D., F. H. Allfrey, M.B., W. Russell, M.C., M.B., L. S. Shoosmith, G. Redpath, M.B., W. B. Honey, M.D., E. Sheffield, M.D., P. A. Sullivan, S. A. Kany, M.B., G. P. Wilson, H. H. Scott, T. C. Reeves, J. F. Gill, M.B., L. Horsley, J. T. Murphy, M.B., A. C. Keay, M.B., M. Krolik, M.D., W. N. Child, W. G. Scott, C. A. E. Ring, F.R.C.S.E., D. J. Dauth, M.B., C. Kidd, M.B., W. Sansom, M.D., W. H. F. F. Godwin, T. J. W. Swinburn, W. S. Sprent, M.D., G. G. Lytle, M.B., A. F. Millar, T. H. Pettit, M.B., A. H. Jacob, L. Lazarus, S. T. Lewis, R. K. Sutherland, M.B., C. A. Drouin, M.D.

To be temporary Captains: J. J. Boyd, M.D., P. D. Magowan, E. V. Frederick, M.B., A. D. Howard, M.D., F. C. Dobie, R. Warren, M.D., F.R.C.S., F. S. Kidd, M.B., F.R.C.S., G. M. de Vine, M.B., H. A. Gillespie, M.B.

Temporary Lieutenants to be temporary Captains: R. H. C. Fryn, D. E. Scott, M.D., R. W. Davies, M.B., M. E. Delefield, M.B., H. L. Messenger, A. Dingwall, M.D., J. W. Applegate, R. H. S. Marshall, P. Rose, A. L. Husband, M.D., H. K. Graham-Hodgson, M.B., E. G. B. Carpenter, F.R.C.S., D. S. Pracy, B. H. Swift, M.B., D. L. Spence, H. B. Scargill, M.B., E. R. Holborow, M.B., R. H. Hadfield, D. J. Foley, M.B., C. J. Brookes, M.B., F.R.C.S., H. I. Pinches, M.B., H. H. Butcher, H. F. Bellamy, M.D., H. B. McCaskie, M.D., R. F. Moore, F.R.C.S., J. Wright, M.B., M. Colt, J. C. Clayton, M. L. Hine, M.D., F.R.C.S., G. Ramford, M.B., J. H. Banks, J. Finnegan, M.D., F. G. Hack, M.B., T. Whitehead, M.B., T. Coogan, M.B., G. L. Irwin, H. P. Aubrey, J. M. Anderson, M.B., H. E. H. Mitchell, M.B., A. P. Adams, I. M. Edis, H. S. Knight, M.B., R. E. Collins, M.B., F.R.C.S., C. M. Young, M.B., S. C. H. Bent, M.D., W. B. Thomson, M.D., A. C. Murray, M.B., F. E. L. Phillips, F. M. Gardner-Medwyn, G. E. E. Nicholls, M.B., V. T. C. Bent, W. C. Swete-Evans, M.D., E. H. B. Oram, M.B., F.R.C.S., A. B. Ross, M.D., E. P. Dewar, G. Viner, M.D., F.R.C.S., J. P. P. Inglis, M.B., F. W. Stuart, M.D., W. Warnock, M.B., W. Gault, M.B., F. W. Perry, P. J. Carroll, M.B., O. R. Belcher, A. Reeves, W. A. Reynolds, W. T. Dobson, J. C. Scott, M.D., F. A. Juler, M.B., F.R.C.S., H. G. Broom, M.D., W. C. Lodwidge, E. A. S. Shaw, F. M. P. Rice, F. Corner, A. S. Dawson, G. H. Baird, M.D., A. Jervis, M.D., J. Dalberg, M.D., R. Haslam, M.B., W. Craik, M.B., J. Lindsay, M.D., D. C. Druitt, H. Greenwood, A. G. Morris, J. W. Gill, M.D., R. M. Coalbank, W. E. Morgan, T. S. Forrest, M.B., S. Godding, M.D., A. D. Campbell, M.B., R. N. West, M.B., F. H. W. Brewer, R. A. Shekleton, M.D., C. A. Harrison, E. E. Lightwood, M. J. Horgan, M.B., W. C. Lattey, R. C. Smith, M.B., R. S. Woods, M.D., W. G. McConnell, A. J. Bado, E. H. Denny, M.B., H. L. de Caux, A. H. Mantfield, W. H. O'Heffernan, J. F. Powell, R. C. Macpherson, M.B., G. T. Symons, H. J. H. Symons, H. H. Castle, W. H. Rayner, M. A. Spotswood, G. D. Gripper, A. C. Dixon, C. R. Howard, M.D., G. A. Lamont, M.B., G. J. C. Ferrier, R. W. Miller, M.B., D. A. Farquharson, M.B., R. G. Michelmore, E. N. Glover, C. J. Todd, H. H. O'Heffernan, C. F. Davey, M.B., R. L. Sinclair, M.B., F. J. McCarthy, V. Lloyd-Evans, M.B., F.R.C.S., A. Grant, M.B., D. R. Adams, M.D., S. J. Brennan, R. D. Brennan, M.B., C. A. Holburn, F. C. Ormerod, G. P. B. Buddy, J. H. D. Webster, M.D., R. M. Gardon, M.B., A. F. W. Denning, M.B., E. D. S. Heyliger, M.B., N. Kennedy, M.B., A. Wilkin, G. J. R. Carruthers, M.B., K. D. Melville, M.D., E. Burstal, M.B., T. W. E. Ross, M.D., F.R.C.S., W. J. Crow, M.B., T. McL. Galloway, F.R.C.S.E., W. S. McLaren, M.B., F. R. Eatock, M.B., W. H. Peacock, M.B., N. S. Carmichael, M.B., F.R.C.P.E., J. McMurphy, E. C. White, M.B., N. E. Kendall, K. G. Haig, J. W. B. Hanington, H. M. Churchill, J. Macfadyen, M.B., E. O. Marks, M.B., T. Stordy, F. G. M. Simpson.

The following temporary Lieutenants relinquish their commissions: D. J. Drake, A. S. Ransome, M.B., H. S. Burns, M.B., A. R. Macdonald, M.B., V. P. G. Pedrick, A. J. S. Pichin, M.D., J. E. Murray, M.D., C. Murray, M.D., G. Dougan, M.D., A. E. Carve, M.D., W. H. Robinson, M.B., J. N. McTurk, M.D., A. E. Whitehead, G. M. Cameron, K. P. Duncan, M.B., A. H. Bloxsome, D. H. Hutchinson, M.D., H. G. Browning, M.B., S. J. Haylock, R. S. Park, M.B., A. G. Reid, M.C., E. Trotter, M.B., F.R.C.S.E., W. R. D. Daglish, M.B., J. W. O. van Millingen, M.B., J. V. Rees, M.B., T. Peebles, M.B., J. G. Jack, M.B., H. Blakemore, J. C. Ellis, P. S. Clarke, W. Dickey, M.B., H. P. Miles, L. Laurie, M.D., F. E. Wate, E. B. Appleby, M.B., E. Evans, A. H. Muir, M.B., M. M. Woods, W. R. Harris, W. McQuibban, M.B., J. J. Gilmore, M.B., P. C. V. Bent, W. T. Melling, M.B., D. I. Connolly, M.B., G. P. Page, T. Dunlop, M.B., M. C. Naylor, J. A. Ure, M.B., J. Maclean, M.B., J. J. Ryan, R. W. Davies, M.B., H. R. Marsh, G. W. Renton.

To be temporary Lieutenants: R. Stanton Woods, M.D., H. D. Matthews, M.B., C. W. Freeman, E. D'A. McCrea, M.B., G. T. Drummond, M.B., I. Ridge-Jones, G. F. N. Taylor, W. L. Locke, M.B., H. W. Crowe, M.D., P. McFadyen, M.B., J. Muckart, M.B., J. R. C. Gordon, J. E. Measham, M.B., G. S. Hett, M.B., F.R.C.S., L. H. D. Thornton, N. Navarria, O. Barton, M.B., J. Masill, M.B., W. A. Dewhurst, M.B., D. G. Pearson, M.B., W. C. Frangoso, M.B., R. B. Johnston, F.R.C.S., G. M. Grundy, M.D., J. A. O'Regan, M.D.,

W. E. Peck, M.B., J. C. Auchencloss, M.B., A. Simpson, M.B., F.R.C.S., D. J. Smith, M.B., R. S. Harper, C. A. Hughes, M.B., J. Wyper, M.B., S. Southall, M.D., J. J. Bekeun, O. C. Gruner, M.D., S. Barron, S. G. Gordon, J. P. S. Dunn, M.B., J. Cullen, M.B., F. G. Sargeant, M.D., W. G. Masefield, A. W. Soper, P. K. Muspratt, M.B., P. Howe, W. H. Edgar, M.B., J. T. B. Hall, M.B., R. G. Meyer, M.B., A. M. M. Roberts, M.B., M. F. Huston, M.B., J. H. Dove, M.B., P. Liston, R. G. Ball, M.B., A. Vost, M.B., T. R. Wilschaw, Second Lieutenant R. D. Passer, M.B., from Gordon Highlanders, Special Reserve.

W. A. Pride, M.B., to be temporary honorary Lieutenant whilst serving with the Crookston War Hospital.

To be temporary honorary Lieutenants: B. McB. Richardson, M.B., J. F. Cooper, M.D., E. A. Cayo, P. D. Spohn, A. H. Good, L. B. Farrior, J. R. Tippins, C. F. Larson.

To be temporary Quartermasters with the honorary rank of Lieutenants: J. T. Thomas, A. H. Owens, J. Currie, J. W. Elvins, L. A. M. Hodson, H. S. Burden, J. Wells, F. F. Grayson.

Temporary Quartermaster and honorary Lieutenant H. Howell relinquishes his commission.

OVERSEAS CONTINGENTS.

CANADIAN ARMY MEDICAL SERVICE.

Assistant Director of Medical Services: Temporary Lieut.-Colonel C. E. Doherty, C.A.M.C., June 20th, 1915 (substituted for notification in the *London Gazette* of August 10th, 1917).

Deputy Assistant Director of Medical Services: Temporary Major F. S. Burke, C.A.M.C.

CANADIAN ARMY MEDICAL CORPS.

Temporary Captain J. R. Goodall to be acting Major while specially employed.

To be temporary Captains: T. Campbell, J. D. Jones, M. Krollk. Quartermaster-Sergeant G. S. Cook to be temporary Quartermaster with the honorary rank of Lieutenant.

SOUTH AFRICAN MEDICAL CORPS.

To be temporary Lieutenants: C. F. Beyers, J. T. McAuslin, M.B., G. R. Cowie.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Captain W. H. L. McCarthy, M.C., M.D., relinquishes the acting rank of Lieut.-Colonel on reposting.

Second Lieutenant H. B. Dykes, M.B., from Unattached List T.F. to be Lieutenant (substituted for notification in the *London Gazette* of August 22nd).

To be Lieutenants: L. K. Ledger, O. C. Carter, H. B. Dodwell, W. U. Longford, and F. E. Bendix, from University of London Contingent O.T.C.; D. McEachran, M.B., J. C. Burda, M.B., S. L. Smith, M.B., J. O. P. Smith, L. Walker, M.B., J. McI. H. Smellie, M.B., R. Mailer, M.B., W. A. Weatherhead, M.B., C. B. B. Reid, M.B., J. S. Bow, M.B., D. W. McLean, M.B., R. Andrew, M.B., J. H. R. Smith, M.B., J. B. Kirk, M.B., J. F. Campbell, J. H. Brown, N. P. R. Galloway, M.B., W. W. Brown, M.B., and F. M. H. Sanderson, from Edinburgh University Contingent O.T.C.; B. W. Jones, M.B., A. Y. Milne, M.B., and C. Reid, M.B., from Aberdeen University Contingent O.T.C.; R. J. L. Fraser, M.B., T. Forrest, M.B., A. B. Austin, M.B., A. B. McA. Lang, M.B., F. W. Sandeman, M.B., D. S. Mitchell, M.B., D. J. MacKinnon, M.B., and J. Joels, M.B., from Glasgow University Contingent O.T.C.; H. Taylor, M.B., from Manchester University Contingent O.T.C.; N. H. S. Maelzer, A. McL. Pickup, J. W. H. Grice, J. J. Conybeare, M.B., J. G. Allan, M.B., H. D. Apergis, C. Wood, M.B., J. M. Savage, M.B.

Lieutenant (on probation) D. J. Steele is confirmed in his rank.

Temporary Captain W. H. F. F. Godwin relinquishes his commission.

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Captain (temporary Major) D. E. Evans, M.B., relinquishes his temporary rank on ceasing to command a field ambulance.

Captain W. Marley-Cass relinquishes his commission on account of ill health contracted on active service, and is granted the honorary rank of Captain (substituted for announcement in the *London Gazette* of April 11th, 1916).

Captain (temporary Major) W. J. Hoyten, M.D., relinquishes his temporary rank.

Captain G. R. Wilson, M.B., to be Major.

Captain R. E. Humphrey is now seconded for duty with a general hospital.

Captain C. P. C. Sargent, from T.F. Reserve, to be Captain.

Lieutenant E. R. Marle to be Captain.

The notification which appeared in the *London Gazette* of June 2nd, 1917, regarding Captain J. W. Heslop is cancelled.

Acting Sergeant-Major J. E. Pritchard to be temporary Quartermaster with the honorary rank of Lieutenant.

Acting Sergeant-Major W. Orr to be Quartermaster with the honorary rank of Lieutenant.

Staff Sergeant R. W. Brearey to be Lieutenant.

Vacancies and Appointments.

VACANCIES.

NOTICES REGARDING APPOINTMENTS.—Attention is called to a Notice (see Index to Advertisements—Important Notice re Appointments) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

APPLECROSS PARISH.—Medical Officer and Public Vaccinator for Torrion District. Emoluments, £350 per annum.

BIRKENHEAD BOROUGH HOSPITAL.—Junior House-Surgeon. Salary, £175.

BIRMINGHAM: LITTLE BROMWICH FEVER HOSPITAL.—Lady Assistant Medical Officer. Salary, £300, rising to £350 per annum.

BOLTON INFIRMARY.—Lady Locumtenent as Assistant Surgeon.

BRISTOL ROYAL INFIRMARY.—(1) House-Physician; (2) House-Surgeon. Salary, £120 per annum.

BRIXTON DISPENSARY, S.W.—Resident Medical Officer. Salary, £200 per annum.

BURY INFIRMARY.—Junior House-Surgeon. Salary, £150 per annum.

CITY OF LONDON MENTAL HOSPITAL, Dartford, Kent.—Temporary Assistant Medical Officer. Salary, £77s. per week.

DERBYSHIRE ROYAL INFIRMARY, Derby.—House-Physician and Casualty Officer. Salary, £200 per annum.

DEVON COUNTY EDUCATION COMMITTEE.—Temporary Oculist. Salary, £8 8s. per week.

GLAMORGAN COUNTY ASYLUM, Bridgend.—Temporary Assistant Medical Officer. Salary, £5 6s. per week.

GLOUCERSHIRE ROYAL INFIRMARY AND EYE INSTITUTION.—Assistant House-Surgeon. Salary, £150 per annum.

GUEST HOSPITAL, Dudley.—(1) Senior Resident Medical Officer. Salary, £150 per annum. (2) Assistant House-Surgeon. Salary, £120 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House-Physician, for six months. Honorarium, 30 guineas.

HOSPITAL OF ST. JOHN AND ST. ELIZABETH, 40, Grove End Road, N.W.3.—Male Resident Officer. Salary, £250 per annum.

HULL: VICTORIA HOSPITAL FOR SICK CHILDREN.—House-Surgeon.

KENSINGTON AND FULHAM GENERAL HOSPITAL, Earls Court, S.W.5.—Resident Medical Officer.

KIRKWALL: PARISH OF EDAY.—Medical Officer.

LEEDS PUBLIC DISPENSARY.—Resident Medical Officer. Salary, £200.

NORWICH: JENNY LIND HOSPITAL FOR SICK CHILDREN.—Lady Resident Medical Officer. Salary, £150 per annum.

NOTTINGHAM AND MIDLAND EYE INFIRMARY.—Ophthalmic House-Surgeon.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham.—Anaesthetist.—Honorarium, £20 per annum.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, Bethnal Green, E.2.—(1) House-Physician. Salary, £100 per annum. (2) Assistant Physician. Honorarium, £25 per annum.

ROTHERHAM HOSPITAL.—Junior House-Surgeon. Salary, £150 per annum.

ROYAL ALBERT EDWARD INFIRMARY, Wigan.—Junior House-Surgeon. Salary, £200 per annum.

ROYAL INFIRMARY, SUNDERLAND.—Lady House-Surgeon. Salary, £200 per annum.

ROYAL PORTSMOUTH HOSPITAL, Portsmouth.—House-Surgeon. Salary, £250 per annum.

ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House-Physician.

SHEFFIELD ROYAL INFIRMARY.—Two House-Surgeons. Salary, £120 per annum each.

SOUTH LONDON HOSPITAL FOR WOMEN, South Side, Clapham Common, S.W.4.—House-Physician and House-Surgeon. Salaries, £100 per annum.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford.—House-Surgeon. Salary, £300 per annum.

WEST BROMWICH DISTRICT HOSPITAL.—Senior House-Surgeon. Salary, £160.

CERTIFYING FACTORY SURGEONS.—The Chief Inspector of Factories announces the following vacant appointment: Long Eaton (Derby).

To ensure notice in this column—which is compiled from our advertisement columns, where full particulars will be found—it is necessary that advertisements should be received not later than the first post on Wednesday morning. Persons interested should refer also to the Index to Advertisements which follows the Table of Contents in the JOURNAL.

APPOINTMENTS.

KIRKMAN, A. H. B., F.R.C.S. Edin., District Medical Officer of the Axminster Union.

KELLY, B. C., M.B., C.M., District Medical Officer of the Crediton Union.

LEICESTER, M. E., L.R.C.P., L.R.C.S. Edin., District Medical Officer of the Leamington Union.

MCCARTHER, D., M.D. Durh., District Medical Officer of the Sudbury Union.

WHITEFIELD, D. W., M.R.C.S. Eng., District Medical Officer of the Uttoxeter Union.

ROSS, H. C., L.R.C.P., M.R.C.S., Assistant Medical Officer of the Fulham Road Infirmary, Westminster Union.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTH.

VICKERS.—On August 14th, at 34, Albert Road, Regent's Park, N.W., to Ida, wife of Captain Harold Vickers, R.A.M.C.(T.), the gift of a son (Harold Edgar).

DEATH.

BEAUMONT.—On September 5th, at 4, Gay Street, Bath, Fanny Elizabeth, wife of W. M. Beaumont and daughter of the late Rev. F. P. Voules, M.A., Rector of Middle Chinnock, Somerset.

CURRENT NOTES.

Discharged Disabled Soldiers and Sailors.

THE letters upon the above subject which appear in the body of the JOURNAL this week have been shown to the Chairman of the Insurance Acts Committee, who asks us to insert the following draft of an explanatory statement which it is proposed to issue to all panel practitioners in the next quarterly circular. Dr. Brackenbury hopes shortly to deal with the various points raised in the letters.

As some misunderstanding appears to exist as to the exact nature of the bargain made for attendance on discharged men, the following remarks may be useful. It seemed obvious to members of the profession that discharged disabled men must necessarily require a greater amount of attendance than ordinary insured persons, but this was by no means accepted as axiomatic by the Commissioners and the Treasury. They indeed suggested that in view of the provision that was being made for special attendance on these men it was possible that they might, as a class, require even less attendance than insured persons generally. Having at last succeeded in convincing the authorities that this was a subject on which insurance practitioners were determined to have satisfaction, the next step was to find out what payment would be adequate. The Insurance Acts Committee was unable to suggest a capitation rate that could be proved to meet the case, as no data were available, and it was finally decided to adopt a plan on the basis of payment per attendance for an experimental period, as that would not only provide a payment for every attendance given, however many, but would prove exactly what relation discharged men bear to the ordinary insured persons as regards the amount of attendance required.

As it cannot be contended that the quality of the attendance required will be higher for the general practitioner treatment of discharged men than for other insured persons it follows logically that the amount per attendance should be a calculated "insurance fee," as in the case of temporary residents. The system in that case was devised to ascertain as accurately as possible the fee per item of attendance which was equivalent to the capitation rate. The temporary resident system for the past three years has worked out at over 95 per cent. of the nominal schedule of fees—that is, at a rate per visit (without medicine) of about 2s. 4½d., and corresponding rates for the other items. There is no reason to suppose that this "insurance fee" will be altered, for it will continue to depend on the same factors that have prevailed from the commencement of National Insurance. Whatever fee results from the operation of the temporary resident scheme will be taken as the unit in paying the accounts rendered for discharged men. There is no fixed pool for the payment of the discharged men's accounts, and every attendance will be paid for at the calculated rate. Thus, if the temporary resident dividend continues to work out at 95 per cent. and a doctor pays fifty visits to discharged men in a quarter he will receive 2s. 4½d. x 50 = £5 18s. 9d. It remains

for practitioners to give adequate attendance to these disabled men and to keep such accounts as will enable them to be paid quarter by quarter such sums as may correspond to the increased call upon their time.

As at one time it seemed improbable that the demand of the profession for the adequate recognition of this increased call upon its services would be recognized by the Treasury, the Insurance Acts Committee considers that the present position is a very satisfactory result of the unanimous expression of feeling of the 1916 Conference of Local Medical and Panel Committees and the action that followed thereon.

Cost of Petrol.

As reported in last week's SUPPLEMENT, p. 57, representations were recently made to the Petrol Control Department drawing attention to the very great advance in the price of petrol, and urging the department to intervene in the matter, and, if necessary, to provide that medical practitioners be supplied with petrol for their professional work at Government rates. A reply has been received from the Deputy Controller of the Petrol Control Department stating that this is not a matter in which the department has any authority to intervene. The letter concludes as follows: "I may add that it is somewhat difficult to see why an increase of 8½d. per gallon in the price of petrol should cause, as your Association appears to anticipate, a serious curtailment of the medical attendance on the civil community. The maximum quantity of petrol allotted to a medical practitioner is 50 gallons a month, or 2 gallons a day, and therefore the additional expenditure incurred by him in consequence of the increased price of petrol can be only 1s. 5d. a day."

CONFERENCE OF REPRESENTATIVES OF
LOCAL MEDICAL AND PANEL
COMMITTEES.

As announced briefly in the JOURNAL last week, a conference of representatives of Local Medical and Panel Committees throughout the country will be held under the auspices of the British Medical Association, at the Crown Room, Connaught Rooms, Great Queen Street, London, W.C., on Thursday, October 18th, at 10 a.m., and following day if necessary. Dr. J. A. Macdonald will act as chairman. The Association will pay all the central expenses of the conference, but it is expected that the Local Medical and Panel Committees will pay the expenses of their representatives. In view of the opinion expressed by the 1916 conference that the larger committees might be allowed more than one representative, Local Medical and Panel Committees of each insurance area are asked jointly to appoint one representative for every 400, or

portion of 400, practitioners upon the medical list of the area for January 1st, 1917. Committees are at liberty to appoint any medical practitioner they like as their representative, whether a member of the Association or not. The members of the Insurance Acts Committee of the Association will, as before, attend the conference and take part in its deliberations, but they will not vote unless they are also elected to the conference as representatives of some Local Medical or Panel Committee. The provisional agenda sheet was issued on September 12th. Motions received not later than the first post on October 8th, at the offices of the Association, will be inserted in the final agenda of the conference. The Insurance Acts Committee will issue this day (September 22nd) an important document with regard to the future of the organization of insurance practitioners, and the position of the Committee as the central negotiating body for Local Medical and Panel Committees throughout the country. It is hoped that all Committees will call meetings to consider this document and the other matters standing on the agenda, and will appoint representatives to attend the conference on October 18th.

Meetings of Branches and Divisions.

LANCASHIRE AND CHESHIRE BRANCH: ROCHDALE DIVISION.
A MEETING of the Rochdale Division was held at Rochdale on September 13th, when Dr. G. GEDDES was in the chair.

Annual Representative Meeting.—Dr. S. T. LORD gave his report of the last Representative Meeting. He drew attention to the fact that money was being spent by the Association in connexion with war emergency work which ought to be found by the country. He considered also that the Association had put an end to too many men being removed from civil practice and taken into the army, and that the Association ought to be boomed and non-members persuaded to join it. Concerted action between different Panel Committees in the country was desirable. Dr. Lord also referred to the proposed Ministry of Health. The following motion was carried:

In view of the loss of interest in, and membership of, the British Medical Association we ask the Association what has become of the arrangement of an Organizing Secretary who was appointed to tour the country to speak to the Divisions on the general policy and action of the Association, in our opinion a very imperative duty.

Dr. Lord was thanked for his attendance at the Representative Meeting.

SOUTH-EASTERN OF IRELAND BRANCH.

AN ordinary meeting of the South-Eastern of Ireland Branch was held in Waterford on September 5th, when Dr. DENIS WALSH was in the chair.

Vote of Sympathy.—A resolution was unanimously passed tendering sympathy to Mrs. Mackesy and family in the loss they have sustained through the death of Dr. G. I. Mackesy, who was one of the oldest and most valued members of the Branch, and a former president.

SOUTH MIDLAND BRANCH: BEDFORD DIVISION.

THE following officers have been elected for 1917-18:

Chairman: Dr. J. Waugh. *Vice-Chairman:* Dr. J. Rollings.
Secretary and Treasurer: Dr. E. R. Fasnacht.
Representative for Representative Meetings: Dr. J. W. Bone.
Deputy Representative: Dr. Kilham Roberts.
Representatives on Branch Council: Drs. A. Chillingworth, G. F. Dixon, K. Roberts, and G. F. Street.
Executive Committee: Drs. G. Butters, Henry Goldsmith, S. J. Ross, and H. Sworder.

Association Notices.

CHANGES OF BOUNDARIES.

Adjustment of Areas of South Staffordshire and Dudley Divisions and Staffordshire and Birmingham Branches.

THE following change has been made in accordance with the Articles and By-laws, and takes effect from the date of publication of this notice:

That Kinver Parish be transferred from the area of the South Staffordshire Division of the Staffordshire Branch to that of the Dudley Division of the Birmingham Branch.

Representation in Representative Body.—Unaffected.

THE LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

A LIST of periodical publications, official reports, and Blue Books in the Library of the British Medical Association available for issue to members on loan has been printed, and copies can be obtained free on application to the Librarian at the house of the Association, 429, Strand, W.C. The regulations governing the loan of these publications are stated in the introduction to the list. The Library is open for consultation from 10 a.m. till 5 p.m. (on Saturdays till 2 p.m.).

SHORTAGE OF MEDICAL STUDENTS.

MEMORANDUM BY THE CENTRAL MEDICAL WAR COMMITTEE.

IN the SUPPLEMENT last week was printed a memorandum on the shortage of medical students, submitted to the Government and the heads of the departments concerned by the Committee of Reference of the Royal College of Physicians, London, and the Royal College of Surgeons of England, together with two resolutions on the same subject passed by the Central Medical War Committee on September 12th. In supporting the memorandum of the Committee of Reference, in a letter dated September 18th to the Secretary of State for War, the Central Medical War Committee states that it desires to make certain additional remarks. These are contained in a memorandum forwarded also to the Prime Minister, the Minister of National Service, the Adjutant-General, the Director-General Army Medical Service, the Medical Director-General R.N., and the President of the Board of Education. This memorandum, which we print below, embodies the two resolutions published last week:

Shortage of Medical Students.

1. The annual average wastage of doctors in normal pre-war times owing to death, retirement from practice, or permanent incapacity is about 900.

2. The average number of medical men added to the *Medical Register* annually is about 1,100 in pre-war times.

3. There is now a large abnormal wastage in qualified medical men arising directly out of the war.

4. The supply of medical men to meet the needs of the civil population has now been reduced to the lowest number consistent with safety, and there is practically no reserve to make good the normal annual wastage from deaths or incapacity.

5. All new additions to the ranks of the medical profession by the qualification of students are at once requisitioned by His Majesty's Forces, and are not available, therefore, to make good the normal average wastage of doctors required for the civil population.

6. The number of fifth year men students due to qualify in 1917 (922) is only barely sufficient to make good the normal wastage in the profession for that year.

7. The number of fourth year men students due to qualify during 1918 is stated in the returns of the General Medical Council to be 1,078. This number has in fact been reduced since these statistics were obtained, by some of the men having accepted commissions as probationary surgeons in the navy, and the number who will actually qualify in 1918 is probably only just sufficient to meet the normal annual wastage, that is, about 900.

8. The number of third year men students due to qualify during 1919 is only 519, and if the greater number of these qualify in due course they will little more than meet half the normal wastage.

9. According to the returns of the General Medical Council (quoted in paragraph 2 of the Memo. of the Committee of Reference) there are 783 second year men students due to qualify in 1920, and 1,432 first year men students due to qualify in 1921. Since these figures were compiled the situation has undergone considerable alteration because:

(a) On February 27th, 1917, a new A.C.I., No. 341, was issued in which previous A.C.I. No. 2,290 of 1916, regarding medical students in any year of their study who were not passed fit for general service (Category A), was altered by the calling up of medical students classified B 1.

(b) A number of medical students of the first and second year of study, who had previously been rejected for military service or classified "C," have been re-examined under the Military Exceptions Act, placed in higher categories, and called up.

(c) First year men as they reach 18 have been called up.

10. Owing to these circumstances the number of first year men students due to qualify in 1921 is probably at the present time not more than half the figure given in the return from the General Medical Council, and the number of second year students is less though probably not to quite the same extent.

11. The average number of medical students registered with the General Medical Council in pre-war times is about 1,500 per annum, but registration with the General Medical Council

is, in cases of students of the University of London and students under the Conjoint Board in England, not now compulsory, so that the actual number of medical students in any one year of study is considerably higher than recorded in the books of the General Medical Council, and probably reaches 1,800 or more, but the figures in paragraph 2 of the Committee of Reference Memorandum include all medical students.

12. The actual shortage, therefore, of first, second, and third year students, as compared with normal pre-war times, is a reduction by about two-thirds.

13. In regard to probationer surgeons in the navy it is important that these (who for the most part are fourth or fifth year men) should be demobilized after six months of service, for otherwise their qualification is being indefinitely postponed. In order to enable this to be done it is necessary that a supply of junior students as they pass their second medical examination should be available, and some of these could become surgeon probationers, and thus make it possible to demobilize those who have served six months.

14. The Central Medical War Committee therefore strongly recommends that medical students who are registered as such in the books of the General Medical Council (or have been accepted as medical students by universities or the Conjoint Board, or, in case of doubt, present a certificate from the dean of their medical school), now serving in the navy or army as officers or privates, should be demobilized to continue their studies.

15. Further, in the opinion of the Central Medical War Committee, the calling up of more medical students, who are registered as such, or who are identified as such, as mentioned in the preceding paragraph, and who have completed their first year of study, should cease.

16. As the medical schools begin their new session in October, it is very important that an early decision on this question should be made by the authorities concerned, so that if it be determined to return enlisted students to their medical studies they may be placed at no disadvantage as compared with others.

INSURANCE.

SCOTTISH INSURANCE ACTS SUBCOMMITTEE.

The Panel Committees of Scotland have recently held an election to decide who should be their representatives on the Insurance Acts Subcommittee (Scotland). The voting was taken by the transferable vote method, and has resulted as follows:

Elected by County Panel Committees.—Dr. Wm. Blair (Jedburgh); Dr. James Hill (Renfrew); Dr. G. C. Anderson (Methil, Fife); Dr. W. R. Martine (Haddington).

Elected by Burgh Panel Committees.—Dr. Michael Dewar (Edinburgh); Dr. Cuthbert Nairn (Greenock); Dr. James Andrew (Coatbridge); Dr. John Gordon (Aberdeen).

LOCAL MEDICAL AND PANEL COMMITTEES.

MIDDLESEX.

At a meeting of the Local Medical and Panel Committees on September 13th Drs. Brackenbury and Burton were chosen as representatives of the Panel Committee at the approaching Conference of Local Medical and Panel Committees.

It was resolved to place the following motion upon the Agenda of the Conference:

That the working out of the settlement for 1916 is so unsatisfactory that the Conference should ask the Insurance Acts Committee to press at as early a date as possible for the increase of remuneration to 10s. per head of insured persons, as suggested in the interim report for the reasons therein given.

NON-PANEL DOCTORS AND NATIONAL INSURANCE CERTIFICATES.

In order to minimize as much as possible the inconveniences caused to doctors who attend insured persons in their private capacity, the Association has published books of certificates which, it is believed, will meet the requirements of approved societies, so far as is practicable in the case of certificates not given under the obligations of the official medical certification rules. The form of certificate is sufficiently like the official form to remove many of the difficulties which insured persons who have been attended by private doctors have had in satisfying the requirements of their approved societies, but is sufficiently distinct from the official form to show at once that it is being used by a doctor who is attending the patient in a private capacity—that is to say, either by a doctor who is not on a panel, or by a panel doctor other than the one on whose list the insured person is.

The Association has shown the certificates to the Insurance Commissions for England, Scotland, and Wales, and they raise no objection to the issue of them by the Association to medical practitioners for use when attending

insured persons not being their panel patients, and not being persons whom they are attending as medical officers of institutions under Section 15 (4), or in virtue of "own arrangements" under Section 15 (3).

The books are being issued at cost price. They contain 50 certificate forms, and may be obtained from the Financial Secretary and Business Manager, British Medical Association, 429, Strand, W.C.2, price 6d. each, post free.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following notifications are announced by the Admiralty:—Fleet Surgeons R. W. G. Stewart, M.B., lent to the Medical Department, Admiralty; A. Woolcombe, and J. L. Pringle, M.B., to the Pembroke. Staff Surgeons C. H. Dawe to the *Sirius*, W. T. Haydon to the *Minerva*, W. L. Hawkins to the *Venus*, J. D. Keir to the *President*, F. C. Robinson to the *Forward*, S. Bradbury to the *Amethyst*, G. D. Walsh to the *Dartmouth*, F. Cock to the *Diligence*. Surgeons W. C. Carson granted the acting rank of Staff Surgeon; G. J. Carr, M.B., to the *Pembroke*, additional, for disposal; A. R. Price to the *Caesar*, R. F. P. Cory to Gibraltar Hospital. Temporary Surgeons: M. Vlasto, M.B., F.R.C.S., to Malta Hospital; F. H. L. Cunningham, M.C., to the *Impregnable*; W. Templeton to Chatham Hospital, A. M. McIlhenny, M.B., to the *Minotaur*; A. F. McIntosh, M.B., to the *Factory*; J. Aydon to the *Temeraire*, R. A. W. Ford to Bermuda Hospital, J. H. B. Hog to the *Pembroke*, H. W. Hales to the *Ajax*, A. G. Bee to the *Hyacinth*, H. W. Addison to the *Thesens*, C. E. S. Harris, M.B., to the *Endeavour*; A. G. McKee to Shotley Sick Quarters, E. F. S. Gordon to the *Dartmouth*. To be temporary Surgeons: W. S. Kidd, M.B., H. E. Cockcroft, J. H. M. Sandison, M.B., E. J. G. Sargent.

ROYAL NAVAL VOLUNTEER RESERVE.

To be Surgeon Probationers: A. L. Brough, P. A. Faichney, H. R. J. Thomas, R. Williamson, J. J. N. Daniels, A. Q. Wells, G. F. Abercrombie, J. I. Moir, C. Joiner, J. G. Reed, R. H. J. M. Corbet.

ARMY MEDICAL SERVICE.

Colonel S. C. Philson is retained on the active list under the provisions of Articles 120 and 522, Royal Warrant for Pay and Promotion, and to be supernumerary.

Colonel J. C. Morgan, from half-pay list, retires on retired pay on account of ill health.

Lieut.-Colonel H. A. Bray, C.M.G., to be temporary Colonel whilst employed as Assistant Director of Medical Services of a Division.

ROYAL ARMY MEDICAL CORPS.

Major B. H. V. Dunbar, D.S.O., M.D., to be acting Lieut.-Colonel whilst holding a special appointment.

The undermentioned are granted temporary rank as stated: As Lieut.-Colonel: Lieut.-Colonel E. J. Moore, C.B., M.P. As Major: Major C. E. M. Lowe, M.B., R.G.A. (T.F.), Major C. J. Caddick, M.B., F.R.C.S.E., R.F.A. (T.F.). As Captain: Captain E. P. W. Wedd, Yeomanry (T.F.), Captain P. T. S. Phillips, M.B., R.F.A.

Temporary Major E. F. Eliot, F.R.C.S.E., relinquishes the acting rank of Lieut.-Colonel on reposting.

Temporary Captain Sir Vincent Nash to be temporary Major.

The surname of temporary Captain David Macquorn-Rankine Crichton, M.B., is as now described, and not as in the *London Gazette* of September 11th, 1915, and October 11th, 1916.

W. C. Stevenson, M.D., Home Hospitals Reserve, to be temporary Captain, August 6th, 1914. (Substituted for notification in the *London Gazette* of October 2nd, 1914.)

The undermentioned having ceased to be employed with No. 1 British Red Cross Hospital relinquish their commissions: Temporary honorary Captains F. Fraser, F.R.C.S., and K. M. Walker, F.R.C.S., M.B.; temporary honorary Lieutenants J. K. Dick, M.B., and F. F. Young, M.D.

The following officers relinquish their commissions: Temporary Captains: F. W. Campbell, E. R. Grieson, M.B., and G. W. Anderson, M.B., J. A. R. Lee, A. W. Owen, M.D., T. G. Williams, M.B., J. Chassels, M.B., temporary Lieutenant E. W. Squire, M.B.

Temporary Lieutenants to be temporary Captains: F. G. Chandler, M.B., T. A. Jones, C. T. Galbraith, M.C., M.B.

Temporary Lieutenants relinquish their commissions on account of ill health: J. Harper, M.B., E. W. Squire, M.B., C. T. Darwent, J. C. Auchincloss.

To be temporary honorary Lieutenants: C. C. Allen and J. H. Dorman.

Quartermaster and honorary Lieutenant A. Harwood to be honorary Captain.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Major H. G. Smeeth, M.D., to be acting Lieutenant-Colonel whilst in command of a field ambulance.

To be Lieutenants: H. G. Morris-Jones from Manchester University Contingent O.T.C.; H. B. Renton, M.B., G. L. Malcolm-Smith, M.B., F. Jones, from Edinburgh University Contingent O.T.C.; J. L. Rowlands, M.B., from Glasgow University Contingent O.T.C.; M. Edwards from University of London Contingent O.T.C.; M. J. Hilton, M.B., from Durham University Contingent O.T.C.

INDIAN MEDICAL SERVICE.

Surgeon-General W. R. Edwards, C.B., C.M.G., Surgeon-General with the Government of Bengal, was appointed an Honorary Physician to His Majesty the King, with effect from February 18th, 1917, to fill an existing vacancy.

Colonel P. Behr, C.B., C.M.G., has been retained in the service as a supernumerary for the period of the war, after completion of his tour of service on March 25th, 1917.

CURRENT NOTES.

American Medical Officers in England.

At the meeting of the Central Medical War Committee on September 26th the substitution of American doctors for civil medical practitioners in military hospitals¹ was considered in connexion with a memorandum submitted by the Chairman of the Committee. The situation having been thus explained to the Committee and debated by them, it was decided that a representation should be made to the Director-General of the Army Medical Service asking that the Committee should be consulted on all matters affecting civilian medical men previous to action being taken. The statements in the lay press that the process of substitution, as far as it has gone, was in accordance with the expressed wishes or views of the Central Medical War Committee were entirely erroneous.

Cost of Petrol.

We have received a number of communications upon this subject. Dr. George L. Lefevre, honorary secretary of the Staffordshire Panel Committee, writes:

I trust that the Medico-Political Committee will not take the answer of the Deputy Controller of the Petrol Control Department as final. He is either ignorant of the facts or chooses to appear so. The net price of petrol to medical practitioners was 1s. 4d. just before the war; it is now 4s. On 50 gallons of petrol per month this represents an increase of £80 per annum. Whatever this works out at per day, it is an increase that very few practitioners can afford, and so long as Government Departments ask for the services of practitioners at pre-war rates they should ensure that the working expenses of the practitioners are kept as far as possible at the former cost.

Dr. A. J. Campbell, honorary secretary of the Berwickshire Panel Committee, forwards a copy of a letter addressed by his committee to the Chancellor of the Exchequer, the National Health Insurance Commission, Scotland, and the Scottish War Emergency Committee, from which we take the following extracts:

At the beginning of 1913, when the medical benefit part of the National Health Insurance Act came into force, petrol cost 1s. 7d. per gallon. It now costs 4s. 6d. per gallon. From the former price doctors were allowed a rebate of 1½d., from the latter a rebate of 6d. per gallon. The difference in actual cost is thus 2s. 6½d. per gallon. Doctors using cars in this district are not likely to get more than eighteen miles per gallon from their petrol. . . . The difference in the price of petrol has added 1s. 7d. to the running cost of every mile we drive. . . . We cannot make all of this good by raising our fees. Much of our private work is done among people to whom the war has brought no increase of income. We have found that, although during the war we have lost many healthy men from our lists, yet a greater proportion of our work is National Health Insurance work than before, since a large number whom we formerly treated as private patients have come on our insured lists. Even if it were not so, it would not be fair to ask our private patients alone to adjust the disturbed balance. The recent rise of 10d. per gallon in the price of petrol has prompted us to voice our grievance now. But there are many other ways in which our working expenses have been increased.

The Berwickshire Panel Committee ask that the hardship may be relieved by an increased capitation fee or mileage grant, or, alternatively, by an additional rebate on petrol taxation.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

The following communication was addressed to the Insurance Commission by the chairman of a Panel Committee on September 24th, 1917:

The Panel Committee for this district meets on Friday, 28th instant, to discuss the new regulation *re* sailors and soldiers discharged and disabled. It will greatly aid us if you will state briefly if my impression of the conditions existing are correct.

The amount paid in on cards for the first half of the year yields the number of 9s. (or less) to be credited to the Central Medical Benefit Fund. No disabled person stamps cards; therefore they are attended for the duration of their disablement for nothing. No discharged disabled sailor or soldier will pay anything to that fund; therefore, so far as the expenditure of 9s. per head of such sailors or soldiers is concerned, it will come out of the Central Medical Benefit Fund to which they have not contributed. A non-panel doctor attending sailors, etc. (as above), would also be paid out of the fund to which no payment has been contributed.

Thus the panel doctors are to be paid out of their earnings from other panel patients and the non-panel doctors are to plunder the scanty funds which should rightly belong to those medical men who have taken up service under the National Health Insurance Commissioners.

I shall be grateful for a reply in time to put before my committee; in the event of none forthcoming we shall conclude that the surmises are correct.

The reply of the Commissioners to this communication was as follows:

September 25th, 1917.

I am directed by the National Health Insurance Commission (England) to acknowledge the receipt of your letter of yesterday's date, and to state that the assumptions set out in your letter are quite contrary to the facts.

The Commissioners have stated in paragraph 43 of Memorandum 229 I.C. that they fully recognize their responsibility for the proper constitution of the central medical pool, and that they have no other purpose in view than to arrive, as accurately as is humanly possible, at the sum of money due to the doctors.

If you will refer to paragraph 28 of that memorandum you will find that the number on which the 9s. per head is calculated is not only the number of stamped contribution cards surrendered by societies in respect of the first half of the year (as stated in your letter), but that this number is supplemented by—

- (1) The number of members aged 70 years and upwards,
- (2) The number of deposit contributors and exempt persons, and
- (3) The number of members of the Navy and Army Fund entitled to medical benefit.

In this last connexion it should be borne in mind that all discharged disabled soldiers who are not members of societies become automatically members of the Navy and Army Fund entitled to medical benefit.

In paragraphs 29 to 31 of the memorandum it is explained that, normally, insured persons who are permanently incapacitated are a set-off in a central pool against excess credits in respect of other classes of insured persons. But in paragraph 39 the special procedure adopted in the 1915 Medical Benefit Settlement is set out, and this course was again adopted at the instance of the medical profession in 1916. It is expressly stated in this paragraph that the total charges for 1915 against societies in respect of medical benefit were calculated on the basis of the charges for 1914, adjustments being made, *inter alia*, in respect of the number of insured persons discharged from the navy and army; these adjustments have the effect of adding the proper credits to the central pool in respect of these discharged persons.

Insurance calculations affecting several millions of insured persons are of necessity complicated, but it should be apparent from the extracts from Memorandum 229 I.C., to which reference has been made, that the original formula, in accordance with

¹ BRITISH MEDICAL JOURNAL, September 22nd, 1917, pp. 395 and 400.

which the central medical pool is calculated, has not been followed blindly, but has, in fact, been the subject of adjustment to meet the conditions created by the return of disabled soldiers and sailors to insurance entitling them to medical benefit, and that it will, in accordance with the general undertaking given by the Commissioners in paragraph 42 of the Memorandum, continue to be adjusted either in that respect or in any other in which revision is called for, in order that the doctors may in fact receive what is due to them.

Nabal and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following notifications are announced by the Admiralty:—Staff Surgeon P. L. Crosbie, F.R.C.S.I., has been promoted to the rank of Fleet Surgeon. Surgeon J. G. Boal, M.B., to the *Skirmisher*. COUNTY OF LONDON.

Co-operation with other Panel Committees.—At the meeting of the London Panel Committee on September 25th a motion was brought forward endorsing the policy of forming an independent association of a directly representative character to co-ordinate the work of Local Medical and Panel Committees and nominating a member to attend a conference in this connexion arranged for October 2nd. Dr. H. B. BRACKENBURY moved an amendment that any decision as to joining a new association be postponed until after the conference convened by the British Medical Association on October 18th. He thought that certain possibilities of accommodation and arrangement in this matter had not been fully explored, and a hurried decision might have regrettable consequences. Dr. J. V. C. DENNING seconded and Dr. J. A. ANGUS opposed the amendment. Dr. H. G. COWIE, the chairman of the subcommittee which had brought forward the recommendation, said that he was quite prepared to assure Dr. Brackenbury that nothing very definite would be done and no special lines of policy taken up until there had been an opportunity of considering and discussing all the questions that might arise on the general situation. Dr. BRACKENBURY accepted this assurance and withdrew his amendment, though he was not prepared to vote for the original proposition, which was carried. A further recommendation electing four delegates to the conference of October 18th was agreed to.

Final Settlement for 1916.—The final settlement for 1916 showed that the amount of money available in the drug fund for that year, after deducting the amounts due to chemists and to practitioners under Article 5, left a balance of just over £11,000 available for transfer to the practitioners' fund for inclusion in the final settlement. This sum represents approximately 2d. out of the "floating sixpence," and is regarded as the result of the committee's campaign for the economical use of the drug tariff. It is the first time this transference has been effected, and the amount more than covers the whole of the administrative expenses of the committee to date.

Complaints against Panel Practitioners Absent on Service.—The Committee agreed that a protest be made to the Commissioners against any complaint lodged by an insured person against a practitioner on the panel being heard during the practitioner's absence on military service.

WEST RIDING OF YORKSHIRE.

At a meeting of the Local Medical and Panel Committee, on September 14th, Dr. Fry (Sowerby Bridge) and Dr. Castle (Dartfield) were appointed to represent the committee at the forthcoming conference of representatives of Local Medical and Panel Committees. The draft scheme for the constitution of the Association of Local Medical and Panel Committees was allowed to lie on the table.

INSURANCE COMMITTEES.

COUNTY OF LONDON.

Medical Benefit for Invalided Sailors and Soldiers.—The London Insurance Committee on September 27th considered the provisional regulations issued by the Commissioners by which medical and sanatorium benefits are

extended to all invalided sailors and soldiers whose total income does not exceed £160 per annum. The new arrangements were accepted, but a resolution was passed regretting that the Committee had not been afforded an opportunity for consultation with the Panel Committee upon the modification of agreements, and a deputation was appointed to discuss the subject in its financial bearings with the Commissioners in view of the additional work thrown on the Committee's staff.

With reference to the administration of sickness, disablement, and maternity benefits to members of the Navy and Army Insurance Fund it was decided also to make representations to the Commissioners on the unsatisfactory position arising out of the present dual control, the indefiniteness of the duties and responsibilities of committees, and the inadequacy of the sums payable towards expenses of administration.

Sanatorium Benefit.—The Committee extended until March 31st, 1919, the agreements already entered into with metropolitan borough councils in respect of dispensary services. A deputation which recently interviewed the President of the Local Government Board on the general treatment of tuberculous persons reported that Mr. Hayes Fisher had expressed the opinion that the whole subject of the treatment of tuberculous persons ought to be reviewed, but if this were not possible at the present time, he felt that at any rate the tuberculosis service in London should be investigated. He did not believe, so far as treatment was concerned, in the division of tuberculous persons into two classes, insured and non-insured, and expressed the opinion that the London County Council might very well review its attitude towards the question and do what Liverpool and other county boroughs and counties had done.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following notifications are announced by the Admiralty:—Fleet Surgeon M. J. Smith, M.D., to the *Conqueror*. Staff Surgeons G. E. Hamilton, M.B., to the *Doris*; T. E. Blunt to the *Woodwich*. British Medical Association.

CURRENT NOTES.

Journal Committee.

THE usual quarterly meeting of the Journal Committee was held on October 3rd, when Major Albert Lucas was re-elected chairman. Dr. Hawthorne and Sir James Barr were elected representatives of the committee on the Finance Committee, of which the Chairman is already a member. The Committee had before it several questions with regard to certain advertisements, upon which it reported to the Council. It adopted without alteration the report of the Subcommittee on the suitability of the JOURNAL and SUPPLEMENT to the present needs of the Association. The findings of this Subcommittee were published in the SUPPLEMENT of June 9th. The opinions expressed were that the present form of the JOURNAL on the whole is suitable, and meets the present needs of the Association, but that members would welcome an increase in the number of contributions on clinical subjects. A recommendation that the column of Current Notes in the SUPPLEMENT should be further developed, and should include reports on the work of committees and sub-committees, it was noted, had already been carried out.

Notification Fees.

The British Medical Association recently brought to the notice of the Local Government Board the fact that certain local authorities were requiring from a medical practitioner a detailed statement of names and addresses of patients, and amount due, before paying for medical certificates under the Notification of Diseases Act. The Medical Secretary pointed out that the demand for such details, already presumably in the possession of the local authority, as a condition of payment, obviously placed on medical practitioners an amount of work out of all proportion to the fee of one shilling. The Local Government Board has replied that the Infectious Disease (Notification) Act of 1889 requires the local authority to pay "for each certificate," and that the Board is not aware of any legal obligation resting upon medical practitioners to send to the authority a statement of fees apart from the certificates themselves. This should dispose of any similar attempt on the part of local authorities to make vexatious stipulations *ultra vires*.

A Ministry of Health.

A meeting of the special subcommittee appointed by the Council to watch this subject in the interests of the medical profession was held on October 9th. It was decided that an invitation should be sent to the Medico-Psychological Association of Great Britain and Ireland to attend the next meeting; and that the Society of Medical Officers of Health and the Society of County Medical Officers should be invited to participate in a conference. The subcommittee had before it the memorandum and bill for the establishment of a Ministry of Health in accordance with the scheme of the National Insurance organizations of the country. It was generally felt that the organizations supporting this bill were in earnest in their intention to press it upon Parliament without delay, and that they had considerable voting power behind them. In view of this it was decided to make a preliminary critical

examination of the text of the bill in order to see how far its various provisions should receive approval or disapproval. Invitations to take part in the discussion upon Major Waldorf Astor's paper on a Ministry of Health, to be read at a meeting on October 31st promoted by the Royal Institute of Public Health, have been accepted on behalf of the Association by Sir Clifford Allbutt, Mr. E. B. Turner, Dr. J. A. Macdonald, Dr. H. B. Brackenbury, and Dr. Cox. The chair will be taken by Mr. H. A. L. Fisher, M.P., Minister of Education. On October 29th a conference of sanitary authorities will be held at the Mansion House, London, to discuss the proposed Ministry of Health and the best means of safeguarding the welfare of motherhood and infancy.

Association Notices.

MEETING OF COUNCIL.

THE next Meeting of Council will be held on Wednesday, October 24th, in the Council Room, 429, Strand, London, W.C.2, at 10 a.m.—By order,

GUY ELLISTON,

Financial Secretary and Business Manager.

October 11th, 1917.

Naval and Military Appointments.

LIVERPOOL INFIRMARY FOR CHILDREN.—Two Resident House-Physicians. Salary, £30 per annum.

NETLEY: WELSH HOSPITAL.—Medical Officer.

NEWCASTLE-UPON-TYNE: ROYAL VICTORIA INFIRMARY.—(1) Four House-Physicians; (2) Five House-Surgeons; (3) Two Accident Room House-Surgeons; (4) One House-Surgeon each to the following departments (a) Aural and Ophthalmic, (b) Gynaecological, (c) Skin and Venereal, (d) Out-patient Dressing.

NORWICH: JENNY LIND HOSPITAL FOR SICK CHILDREN.—Lady Resident Medical Officer. Salary, £250 per annum.

OLDHAM ROYAL INFIRMARY.—Third House-Surgeon. Salary, £225 per annum.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham.—Senior House-Surgeon. Salary, £7 7s. per week.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.—(1) House-Physician. (2) Casualty House-Surgeon. (3) House-Surgeon. Salary, £100 per annum.

READING: ROYAL BERKSHIRE HOSPITAL.—House-Surgeon. Salary, £250 per annum.

RICHMOND: ROYAL HOSPITAL.—Qualified Refractionist. Honorarium, £25 per annum.

ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, Great Portland Street, W.—Resident House-Surgeon. Salary, £100 per annum.

SHEFFIELD: THE ROYAL INFIRMARY.—House-Physician. Salary, £120 per annum.

SHREWSBURY: ROYAL SALOP INFIRMARY.—House-Physician. Salary, £200 per annum.

STOKE-ON-TRENT COUNTY BOROUGH.—Assistant Lady Medical Officer. Salary, £350 per annum.

TRURO: ROYAL CORNWALL INFIRMARY.—House-Surgeon. Salary, £150 per annum.

WALSAIL AND DISTRICT HOSPITAL.—Assistant House-Surgeon and Anaesthetist. Salary, £175 per annum.

WEST BROMWICH DISTRICT HOSPITAL.—Senior House-Surgeon. Salary, £160.

WOLVERHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY.—House-Surgeon. Salary, £150 per annum.

CERTIFYING FACTORY SURGEONS.—The Chief Inspector of Factories announces the following vacant appointments: Gunnislake (Cornwall), Muirkirk (Ayr).

To ensure notice in this column—which is compiled from our advertisement columns, where full particulars will be found—it is necessary that advertisements should be received not later than the first post on Wednesday morning. Persons interested should refer also to the Index to Advertisements which follows the Table of Contents in the JOURNAL.

APPOINTMENTS.

HOMER, C., L.R.C.P. and S. Edin., L.R.F.P.S. Glasg., District Medical Officer of the Nuneaton and Foleshill Unions.

SALT, A. P., M.R.C.S., L.R.C.P., Medical Officer of the Totnes Union Workhouse.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTHS.

BLAXLAND.—On October 4th, at the Surrey Street Nursing Home, the wife of Jasper Blaxland, M.S. (Captain R.A.M.C.T.F.), of a son.

CLARK.—On October 4th, at 20, South Avenue, Rochester, to the wife of Surgeon A. B. Clark, M.B., B.S. (of H.M.S. *Galatea*), the gift of a daughter.

MARRIAGES.

GRAY—FERGUSON.—On October 5th, at St. Mary Abbot's, Kensington, by the Rev. W. H. Ferguson, M.A., Warden of St. Edward's School, Oxford, uncle of the bride, Adam Gray, M.D. Aberd., Captain R.A.M.C., to Florence Joan, second daughter of R. Bruce Ferguson, M.A., M.D. Cantab., D.P.H., of New Southgate.

HARKER—DYSON.—On Wednesday, September 12th, at the Church of Emmanuel, Southport, by the Rev. F. W. Dwelly, Vicar, assisted by the Rev. W. V. Walmesley, Captain Thomas H. Harker, R.A.M.C., youngest son of Mr. and the late Mrs. John Harker, of Teddington, to Ethel Dean, only child of Mr. and Mrs. Edwin Dyson, of Southport.

HARTLEY—EVANS.—On the 5th inst., at Four Oaks Wesleyan Church, by the father of the bridegroom, Lieutenant G. Cleverdon Hartley, M.C., M.B., Ch.B., R.A.M.C., son of Rev. and Mrs. J. W. Hartley, of Chester Road, Birmingham, to A. Muriel Evans, M.B., Ch.B., daughter of Mr. and Mrs. J. Evans, of Streetly Lane, Sutton Coldfield.

TAYLOR—MOCKLER.—On October 6th, at St. Michael's Church, Blackrock, by the Very Rev. Canon P. Tracey Kilmurray, cousin of the bride, Charles Joseph Gordon Taylor, M.A., M.B. Oxon., Surgeon R.N.V.R., only son of Charles Louis and Marie Taylor, 54, Glenloch Road, Hampstead, N.W.3, to Annette Josephine, second daughter of Thomas and Caroline Mockler, of Ardeen, Blackrock, Cork.

DIARY FOR THE WEEK.

TUESDAY.

MEDICO-LEGAL SOCIETY, 11, Chandos Street, W., 8.30 p.m.—(1) Presidential Address. (2) Discussion on the Criminal Law Amendment Bill, 1917, to be introduced by Dr. F. J. Smith.

THURSDAY.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W., 4 p.m.—Harveian Oration by Dr. Robert Saundby.

FRIDAY.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos Street, W., 5.30 p.m.—Presidential Address by Sir David Bruce, C.B., F.R.S., on "Tetanus: Analysis of 1,000 Cases," with discussion.

ROYAL SOCIETY OF MEDICINE.—Section of the History of Medicine: Wednesday, 4.30 p.m., Exhibition of Books, Pictures, etc., 5 p.m., Notes by Sir William Osler, Professor F. C. Van Leeuwen (Amsterdam), Dr. Henry Barnes, and Lieut.-Colonel D'Arcy Power on Boerhaave. Section of Dermatology: Thursday, 4.30 p.m., Cases. Section of Electro-Therapeutics: Friday, 8.30 p.m., Address by the President, Dr. Harrison Orton.

DIARY OF THE ASSOCIATION.

Date. Meetings to be Held.

OCTOBER.

- 17 Wed. London: Finance Committee, 2.30.
- 18 Thurs. London: Conference of Representatives of Local Medical and Panel Committees, 10 a.m., at Connaught Rooms, Great Queen Street, W.C.2, Dr. J. A. Macdonald, LL.D., in the chair.
- 24 Wed. London: Council Meeting, 10 a.m.

CURRENT NOTES.

Grievances of Territorial Medical Officers.

IN reply to inquiries as to the probable date of issue of the further report of the Departmental Committee on anomalies of promotion, etc., among officers of the Territorial Force and new armies, the British Medical Association has been informed that the further report is now being considered by the military authorities, but cannot be issued to the public until a decision with regard to the recommendations has been arrived at. It is hoped that the report will be issued shortly.

Non-Medical Officers of the R.A.M.C.(T.F.).

The attention of the Naval and Military Committee has been drawn to instances of laymen holding commissions in the R.A.M.C.(T.F.). The Committee realizes that this is a matter which must be taken up carefully in due course; but, in view of the fact that Regulations 73 and 74 of the Territorial Force Regulations, which were in operation prior to the present war, permit other than registered medical practitioners to hold commissions in sanitary companies, it has decided to postpone further consideration of the matter until a more suitable opportunity occurs.

Indian Practitioners and Combatant Service.

As reported under this heading in the SUPPLEMENT of June 30th, 1917, the Association made representations to the Secretary of State for India, urging that qualified medical practitioners in India deemed to be enrolled under the Defence Force Act, who are willing to accept, if offered, a commission in the R.A.M.C. or I.M.S., shall be exempted from combatant training or service. The Association has been informed, in reply, that orders have been issued in India to the military authorities that no qualified medical practitioners are to be required to do drills, pending consideration of the question of using their services in a professional capacity in connexion with the Indian Defence Force, and that as soon as a decision has been reached on this question a further communication will be addressed to the Association.

DISCHARGED DISABLED SOLDIERS AND SAILORS.

ON October 8th a letter was addressed by the Medical Secretary of the British Medical Association to the Insurance Commissioners with regard to the new regulations for the remuneration of practitioners treating discharged disabled soldiers and sailors, asking that a consecutive analysis of the actuarial situation might be furnished for the information of the conference of Local Medical and Panel Committees on October 18th. In compliance with this request the Insurance Commissioners forwarded a copy of the following memorandum on the sources, and the method of calculation, of the remuneration of doctors undertaking the general practitioner treatment of discharged disabled sailors and soldiers:

MEMORANDUM BY THE INSURANCE COMMISSION.

1. The return to civil life of sailors and soldiers discharged on account of injuries or ill health, mostly insured and nearly all entitled to general practitioner treatment under arrangements made by the Insurance Commissioners, has made it necessary to modify in certain respects the methods previously adopted for calculating the payment of doctors undertaking the treatment of insured persons.

2. In the first place, many of these discharged men will be unfit to enter employment, at all events for some time, and the bringing into reckoning of an abnormal number of persons who (through unemployment) do not surrender contribution cards and yet are entitled to treatment, has obviously introduced a disturbing element into the normal calculation of the number of units on which the amount of the central pool for the remuneration of doctors is based.

3. Secondly, it is believed by the medical profession generally that those persons will, as a class, require more attendances per head than would an equal number of persons drawn at random from the main insured population, and, therefore, that a sum per head per annum which might suffice for the latter class would be inadequate in respect of the former.

4. In order to meet the second of these points (so far as experience may show it to be sound) the Government have, through the recently issued Regulations concerning treatment of discharged disabled sailors and soldiers, instituted a new system of remuneration (based upon payment per attendance) to apply in the case of all sailors and soldiers discharged after a certain date, and in the case of those discharged before that date for whom the doctor desires to be paid under this new system. The doctors' bills under this system will be paid out of a special fund—the "Invalided Soldiers Medical Benefit Fund"—to which will be transferred from the General Medical Benefit Fund the full sum of 9s. per annum in respect of every discharged man who is being treated under the payment per attendance system, and in respect of whose treatment the General Medical Benefit Fund is liable. If the aggregate of these sums proves insufficient to meet the liability, the Exchequer has undertaken to make good the deficiency.

5. Concerning the first disturbing element, mentioned in paragraph 2 above, the modifications in the calculations thereby rendered necessary have naturally been in fact duly made in the ordinary course. It appears, however, that many members of the profession who had not perceived the need for such alterations until the issue of the new Regulations bearing directly on the second point have now become apprehensive as to whether any allowance, and, if any, a sufficient allowance, has been made for the purpose. To dispose of these apprehensions it is thought well that a statement should be issued, showing in a way as little technical as possible what are the sources from which the money is drawn that will be paid for the treatment of discharged disabled sailors and soldiers, and how the sums made available are arrived at.

6. The class of persons in question falls mainly* into three groups, namely:

(i) A very large number who either were members of approved societies before joining the forces and remain members or join approved societies on discharge;

(ii) A considerable number who, although insured, are not and cannot become members of approved

* There are also deposit contributors and exempt persons who are an insignificant minority.

societies, and the cost of whose treatment is therefore borne by the Navy and Army Insurance Fund, constituted under Section 46 (3) of the Insurance Act, 1911; and

(iii) A small number who are not insured under the Insurance Acts at the time of their discharge, but become entitled, if their income is under £160 a year, to medical benefit as though they were insured (though not to any cash benefits), in pursuance of the provisions of Section 4 of the National Insurance, Part I, Amendment Act, 1917.

7. The payment in respect of the first of these three groups is derived from the funds of approved societies and the Exchequer, in the same way as is that of insured persons generally who are members of approved societies. As the doubts and misunderstandings which this document is intended to remove have been experienced chiefly, it would appear, in reference to this class, it is convenient to dispose first of the other two groups, namely, the members of the Navy and Army Fund and the uninsured.

8. The Navy and Army Fund provides the ordinary benefits of the National Insurance Acts for all discharged sailors and soldiers whose state of health is such that they cannot obtain admission to an approved society. The sum of 9s. per head per annum for the medical benefit for these men, therefore, is paid from that fund to the General Medical Benefit Fund. The cost of the medical benefit of uninsured persons, whose income from all sources is less than £160 a year, will likewise be paid for out of the Navy and Army Fund. There is no difficulty in calculating the numbers concerned under either of these heads, as it is directly ascertainable from definite information in the hands of the Insurance Commissioners. It follows that, in respect of these two classes of persons, there can be no possibility of the money to pay for their treatment being taken from funds which ought to go to the doctors in respect of the treatment of other insured persons. Moreover, the solvency of the Navy and Army Insurance Fund being guaranteed from the Exchequer, there can be no doubt as to the sum of 9s. per head being available to pay for the treatment of all persons for whose treatment that fund is liable.

9. It is, therefore, in respect of those only who are members of approved societies that there are intricacies in the calculation which might afford a possible basis for doubt in the doctors' minds on the two points of whether the right amounts are being paid into the central pool for treatment of discharged men, and of whether the payments out of that pool in respect of such treatment operate in reduction of money that doctors ought to receive for treatment of other insured persons. To make clear how the calculation for this group is made, it is necessary to recapitulate the substance of the explanations given in Memo. 229/I.C. as to the normal method of calculation of the central pool for the payment for medical benefit—that is, the General Medical Benefit Fund.

10. As pointed out in Memorandum 229/I.C., the amount to be paid in respect of treatment of insured persons is one that cannot, for the following reasons, be calculated by direct observation of the number of persons entitled to treatment and the periods during which each is so entitled. The amount payable annually is 9s. per head of those entitled to treatment for the whole year. It is not 9s. for every person who is entitled to treatment for a period short of a year; still less could it be 9s. for every person who is at a particular moment entitled to treatment. For a man who is in benefit for (say) 1/6th of the calendar year, 1/6th of 9s. is payable. The number paid on is, in effect, an aggregate of "insured person days"—that is, days during which doctors were under liability to treat insured persons, or (to use the convenient term customary in dealing with all kinds of insurance) "at risk" in respect of insured persons. The unit is one day's risk in respect of one person, and for this there is to be paid into the national pool 1/365th part of 9s. This sum could only be calculated directly if it were possible to follow the movements of every insured person from day to day, and thus ascertain by direct observation for how many days each person separately had been entitled to treatment throughout the year.

11. It will be seen that the difficulties which make direct calculation impossible are of a kind which cannot be removed by any act of mere administration; they are inherent in the particular system of remuneration which the profession in 1911-12 made a condition of acceptance of service under the Insurance Acts, and can only be removed, therefore, if and when a simpler system can be agreed upon in some revision of the general bargain. In the meantime it is necessary to make use of relevant

known facts, becoming available in the ordinary course of insurance administration, from which by a process of reliable inference the true number required can be ascertained.

12. After careful investigation by the Government Actuary, it was found that the most suitable basis for the purpose is the number of stamped contribution cards surrendered by members of approved societies in respect of the first half of the year. In considering what alteration, if any, of this number is necessary in order to arrive at the number which is to be ascertained—namely, the number of persons respecting whom the doctors were in the aggregate at risk for a full year—the following points of divergence in opposite directions have to be taken into account.

13. On the one hand, the card number obviously errs by *excess* in comparison with the true number to be ascertained, because it treats as persons for whom doctors are at risk throughout the whole year very many persons for whom they are really at risk for part only of the year, for example, a person who was in insurance at the beginning of the year and dies in the course of it, or a person who only comes into insurance at some late date in the first six months. If a card be surrendered, as above stated, the man who dies (say) in January, after being employed for even one week only, and the man who does not enter into insurance until (say) June 1st, are treated in the card number calculation exactly as though medical benefit had to be provided for each of them for a *whole* year. In respect of these, therefore, to take the card number uncorrected would result in an overcharge against societies and an overpayment of doctors.

14. On the other hand, the card number errs by *defect*, since it takes no account of persons who do not come into insurance until the second part of the year, or of persons who (from permanent or temporary incapacity or other cause) are unemployed throughout the first half of the year. For these persons no cards are surrendered in respect of the first half-year, and as regards these, therefore, the adoption of the uncorrected card figure would lead to an underpayment of doctors, too small a charge being made on societies.

15. These two sets of differences, one set *plus* and one set *minus*, have to be balanced against one another to arrive at the true figure. The weighing of the relevant considerations as to the number of persons included in each of the balancing elements of the calculation is essentially an actuarial problem, and the Government Actuary has come to the conclusion that these two sets of differences are, *under ordinary working conditions*, practically equal—that is to say, that *under those conditions* the number ascertained by counting the stamped contribution cards surrendered in respect of the first half of the year may fairly be taken as equivalent to the number or units in respect of which the full annual charge should be made on approved societies and paid into the General Medical Benefit Fund.

16. The general conclusion stated in the preceding paragraph relates, as has been pointed out, to ordinary conditions. The validity of it in application to any particular year plainly depends, in part, on the fact that no one of the fluctuating items in the calculation (for example, the number of permanently disabled persons, or the number of persons who for any temporary cause surrender no card in respect of the first half of the year, but become entitled to benefit in the second half) can increase or diminish substantially, in reference to the others, without the existence of such a change becoming known to those responsible for the calculation, who will thus be enabled to make whatever correction may be necessary.

17. Now the war conditions have, in fact, as was pointed out in Paragraph 42 of Memorandum 229/I.C., introduced such disturbances. In the first place, war enlistments obviously have the effect that a much larger proportion than in ordinary times of those who surrender cards in respect of the first half-year (and who therefore under the normal conditions would be taken as units on which 9s. each must be paid) pass out of insurance in the course of the year, and thus the doctors are no longer at risk concerning them in the remainder of the year. Hence an overcharge on the societies and an overpayment of the doctors would result if no correction were made.

18. It was further pointed out in Paragraph 42 of Memorandum 229/I.C. that it must be expected that discharges of invalided men from the army would, in time, constitute a disturbing element in the opposite direction, for which an allowance should and would be made when the occasion arose. Discharged invalided men are, with few exceptions, persons in respect of whom the doctors become at risk from the time of their discharge; but contribution

cards will not come into the reckoning, except in respect of those members of approved societies who enter into employment in the first half of the year. Thus the effect of discharges is to increase abnormally the number of those for whom, though the doctors are at risk, no card is surrendered. Some addition must therefore be made to the card number in order that it may represent the true number; otherwise there would be an undercharge on societies and underpayment of doctors.

19. Thus, taking the net effect of war conditions on the calculation, at a time when both enlistments and discharges are operating as substantial disturbing causes, there must be both deductions in respect to the former and additions in respect of the latter. The calculation of these deductions and additions has been duly carried out (on the basis of particulars of enlistments and discharges furnished confidentially by the Admiralty and War Office to the Government Actuary) with the object of securing that the number of units on which the payments into the central pool are based shall be as closely as possible equivalent to the true number to be ascertained; and the Government Actuary has expressed his professional opinion that this object has in fact been attained, at all events within so close a measure of accuracy that the margin of error cannot in fact have exceeded a quite minute fraction, representing certainly less than a penny in the £ of the sum paid into the pool, and this (he says), if it has occurred at all, is practically as likely to have been too much as too little.

National Health Insurance Commission,
October, 1917.

Association Notices.

MEETING OF COUNCIL.

The next Meeting of Council will be held on Wednesday, October 24th, in the Council Room, 429, Strand, London, W.C.2, at 10 a.m.—By order,

GUY ELLISTON,

Financial Secretary and Business Manager.

October 11th, 1917.

ELECTION OF MEMBERS OF COUNCIL, 1918-19, BY BRANCHES OUTSIDE THE UNITED KINGDOM.

NOTICE is hereby given that, in accordance with By-law 49, nominations of candidates for election as members of Council by the grouped Branches outside the United Kingdom for a period not exceeding three years, as prescribed by By-law 52 (2), must be forwarded in writing so as to reach me on or before February 15th, 1918.

Nomination papers may be signed by not less than three members of any Branch comprised in the group, and must be in the form prescribed below or in a form to the like effect.

Election will be by voting papers, which will contain the names of all duly nominated candidates, and will be issued from the head office in London to each member of each Branch comprised in the group.

By order of the Council,

GUY ELLISTON,

Financial Secretary and Business Manager.

429, Strand, London, W.C. 2.

October 13th, 1917.

NOMINATION FORM.

BY NOT LESS THAN THREE MEMBERS OF THE GROUPED BRANCHES.

We, the undersigned, hereby nominate

.....
of.....

[Full name and address must be given]

as a candidate for election by the (here state the names of the Branches in the group) Branches as a member of the Council of the Association.

Names and addresses of nominators, and Branches to which they belong.

Signature and Address.

Branch.

Date..... 19..

This form should be forwarded to the Financial Secretary and Business Manager, 429, Strand, London, W.C. 2, so as to be received not later than February 15th, 1918.

Not later than the second week in June, 1918, a notice of the result of the election will be published in the JOURNAL.

GROUPING OF BRANCHES NOT IN THE UNITED KINGDOM FOR REPRESENTATION ON COUNCIL OF ASSOCIATION, 1918-19.

	No. to be elected.
South Australian, Tasmanian, Victorian, Western Australian	1
New South Wales, Queensland	1
New Zealand	1
Barbados, Bermuda, British Guiana, Grenada, Halifax (Nova Scotia), Jamaica, Leeward Islands, Montreal, St. John (New Brunswick), Saskatchewan, Toronto, Trinidad and Tobago	1
Assam, Baluchistan, Bombay, Burma, Ceylon, Hyderabad and Central Provinces, Punjab, South Indian and Madras	1
Hong Kong and China, Malaya	1
Border (South Africa), Cape of Good Hope (Eastern), Cape of Good Hope (Western), East Africa and Uganda, Egyptian, Gibraltar, Griqualand West, Malta and Mediterranean, Natal Coastal, Natal Inland, Orange Free State, Pretoria, Rhodesian, Witwatersrand	1

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty:—Staff Surgeons W. N. Blatchford to the *Penelope*, C. V. Griffiths to the *Weymouth*, R. Connell, M.B., to the *Penbrooke*, D. D. Turner to the *Fivid*, additional, Surgeon W. J. Stitt granted the acting rank of Staff Surgeon. Temporary Surgeons R. C. J. Meyer to the *Fivid*, H. Parry-Price to the *Lion*, P. Macarthur, M.B., to Haslar Hospital; W. E. Powell to Haslar Hospital; G. E. Burton, E. J. Tongue, and W. F. W. Betenson to the *Fivid*, additional. To be temporary Surgeon: S. Hutchinson.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Probationers: E. N. D. Reppey and H. N. Witham to the *Victory*, for course at Haslar Hospital; H. R. Bulmer to the *Broke*, D. B. Wilson to the *Atridi*. To be Surgeon Probationers: H. J. Horne, A. W. Hart, R. G. Anthony, F. H. Molliere, J. S. E. Manley, R. C. Williams, A. J. Constance, G. G. Graham.

ARMY MEDICAL SERVICE.

Surgeon-General R. H. S. Sawyer, C.M.G., M.B., F.R.C.S.I., is retained on the active list under the provisions of Articles 120 and 522, Royal Warrant for Pay and Promotion, and to be supernumerary. Lieut. Colonel H. Gilbert Barling, C.B., F.R.C.S., R.A.M.C.T.F., to be temporary Colonel.

ROYAL ARMY MEDICAL CORPS.

Lieut. Colonel T. E. Sandall, M.B., Lincolnshire Regiment, T.F., to be temporary Lieut. Colonel.

The following relinquish the acting rank of Lieut. Colonel on reposting: Captain E. D. Caddell, M.C., M.B., Major B. H. V. Dunbar, D.S.O., M.D.

Temporary honorary Lieut. Colonel L. C. Parkes, M.D. (Major R.A.M.C.T.F.), relinquishes his temporary honorary rank.

Temporary Major A. A. Mussen, M.D. (Major R.A.M.C.(T.F.)), relinquishes his temporary commission on reposting.

Temporary honorary Major E. W. White, M.B., to be temporary honorary Lieut. Colonel.

The notifications regarding temporary Captains S. J. Staples, M.B., and A. F. Millar in the *London Gazette* of August 4th and September 7th respectively are cancelled.

Temporary Major (Captain R.A.M.C.T.F.) F. A. Hepworth, F.R.C.S., relinquishes his temporary rank on reposting.

Temporary Captain F. F. Middleweek to be temporary Major whilst commanding troops on a hospital ship.

Temporary Captain T. R. Davey relinquishes his commission on account of ill health.

H. H. Scott, late temporary Captain, is granted the honorary rank of Captain.

Temporary Captains W. Allan, M.B., and F. G. Martin relinquish their commissions, and are granted the honorary rank of Captain.

Temporary Captains relinquish their commissions: J. L. Gregory, M.B., A. Frew, M.D., H. S. Tait, M.D., I. Wilson, M.D., T. Campbell, M.B., G. A. Simmons, M.D., W. P. MacKasey, M.D., R. B. Lilly, J. A. Longley, M.B., F.R.C.S., K. B. Aikman, J. A. Cowan, M.B., C. Dickson, M.D., R. K. Sutherland, M.B., O. M. de Jong, M.B., N. A. Scott, J. S. Stewart, M.C., M.B., R. D. O'Leary, M.B., J. G. Greenfield, M.B., J. H. Ritchie, M.C., M.B., C. L. Dold, M.B., H. J. Burke, M.C., S. A. O. Mackenzie, F.R.C.S.E., G. W. Kendall, M.D., H. M. Hart-Smith, M.B., J. D. Jones, J. T. Mackenzie, M.C., G. L. K. Finlay, M.B., E. O'Connor, M.B., A. W. Bourne, M.B., F.R.C.S., R. M. Alcorn, J. C. T. Teggart, M.B., L. C. E. Murphy, H. Wales, M.B., C. R. Hoskin, M.D., F. J. Hathaway, M.D., W. J. D. Robertson, M.B., G. N. B. Sebastian, R. P. Graham, D. M. Gill, M.B., D. McKarl, M.D., J. Macarthur, M.B., T. Milling, M.B., G. F. Gill, T. H. James, J. Crowley, D. St. C. Creighton, M.D., R. J. Kee, M.B., J. W. Darling, M.C., M.B., P. M. Turnbull, M.C., M.B., D. McD. Wilson, M.C., M.B., T. Redmayne, M.B., F.R.C.S., R. H. L. O'Callaghan, M.D.

B. Lyons, M.B., to be temporary Captain.

Temporary Lieutenant Anthony S. Rose is dismissed the service by sentence of a general court-martial, September 28th.

Temporary Lieutenants to be temporary Captains: J. W. Wraye, M.C., A. S. Cook, M.B., A. J. M. Crighton, M.B., G. H. Sinclair, M.B., G. D. Compston, R. C. Allen, H. E. Scoones, C. T. I. Clarke, M.B., W. R. Wylie, M.B., R. W. Howell, M.B., F.R.C.S., W. I. Adams, F.R.C.S.I., C. B. Hutchinson, J. A. H. White, M.D., C. I. Stockley, M.B., R. H. Maingot, J. M. Adams, M.B., H. North, E. Williams, J. Maguire, H. Somerville, L. Kilroe, M.D., A. J. P. Nowell, M.B., H. Granger, W. L. Johnston, M.B., R. Cunliffe, M.B., J. E. Spence, M.B., J. W. Miller, M.B., E. D. Richardson, J. H. McAllum, S. C. Pritchard, M.D., H. Case, J. Forrest, M.B., S. F. Lusk, M.B., J. W. Elliott, H. Angel, M.B., R. T. Dobson, M.B., P. W. Leathart, M.B., P. Levick, M.B., A. H. Clarke, W. P. Pinder, F. CONFERENCE OF REPRESENTATIVES OF LOCAL MEDICAL AND PANEL COMMITTEES.

London, Thursday, October 18th, 1917.

A CONFERENCE of representatives of Local Medical and Panel Committees, called by the British Medical Association, was held at the Connaught Rooms, Great Queen Street, London, on October 18th. Dr. J. A. MACDONALD, LL.D., Chairman of Council of the Association, presided, and 137 representatives attended, representing 150 insurance areas, together with eight members of the Insurance Acts Committee who were not representatives. Of the 127 insurance areas in England, 114 were represented at the Conference, of the 56 Scottish insurance areas 25 were represented, and of the 17 Welsh areas 11 were represented.

Representatives appointed to attend the Conference by the following areas were unable to be present: Rutlandshire, Cumberland, Chester, Derby, South Shields, Kirkcaldy, and Monmouthshire. Eight Scottish areas and one English area which were not represented at the Conference wrote expressing their continued confidence in the Insurance Acts Committee as the central negotiating body.

DIRECT REPRESENTATIVES ON INSURANCE ACTS COMMITTEE.

After the standing orders had been adopted and the return of representatives received, the CHAIRMAN moved the reception of the scheme for nomination by grouped Local Medical and Panel Committees of fifteen practitioners for election to the Insurance Acts Committee.

Captain E. R. FOTHERGILL (Committee) drew attention to two motions on the agenda, one expressing renewed confidence in that Committee, the other expressing the reverse, and he urged that before the Conference proceeded to form and instruct the Committee for the future it was necessary to decide whether the Committee was to continue to be the central negotiating body or whether some totally new system was to be set up. If the Conference was going to be so foolish as to decide against the Association and its Committee, it was obvious that this matter of nominations would be considerably modified. Therefore, it seemed the most sensible course to proceed at once to discuss the motion of confidence.

The CHAIRMAN said that the motions with regard to the nominations were purely formal, and were brought forward at this stage to regulate the procedure for the day.

Furthermore, the work of the Committee in the past must be discussed before they came to the motions which decided what they should do in the future.

Dr. H. B. BRACKENBURY (Chairman of the Committee) then moved the approval of the scheme for nominations, and said that he understood that in Scotland there was some desire that the two members should be allocated, one to one part of the country and the second to another.

Dr. J. R. DREVER (Glasgow) said that the recently constituted Insurance Acts Subcommittee for Scotland had unanimously agreed to allocate one to industrial and the other to rural areas.

Dr. T. CUMING ASKIN (Suffolk, E.) objected to the election taking place on that day. The hurry of the Conference furnished not quite a suitable atmosphere for an important election. The proper course to adopt would be, after nominations by each Panel Committee, to have a postal vote, which would afford a means of deciding the merits of the candidates. He moved an amendment to that effect, which was seconded by Major D. F. TODD (Durham).

Dr. E. H. M. STANCOMB (Southampton) strongly supported this amendment. The increased representation would not indicate the real feelings of Panel Committees because these latter had had no fair opportunity of expressing their views as to the claims of the various candidates. The present scheme did not provide them with the direct representation which they had a right to expect and for which they asked at the last Conference.

The CHAIRMAN said that he was in sympathy with the suggestion contained in the amendment, but if it were adopted on the present occasion it would take some time to carry out, and meanwhile the Committee had to continue its work.

Dr. JAMES HOLMES (Bury) said that at that Conference they knew one another fairly well, and he thought that such a comparatively small body as theirs was in a better position to make nominations than the general body of committees all over the country.

Dr. BRACKENBURY said that theoretically he was on the side of the amendment. The more democratic they could be the better for all concerned; but this was purely a matter of convenience. Certain Panel Committees had already sent representatives to that Conference with

instructions to vote definitely for certain individuals, and if those instructions had to go by the board, other resolutions must go by the board as well. The proposal was, perhaps, a good one for future years, but its present effect would be considerable delay.

The amendment was lost, and the scheme of nomination approved.

THE WORK OF THE INSURANCE ACTS COMMITTEE.

The report as to action taken by the Committee since last Conference having been received,

Captain FOTHERGILL again urged that the motion of confidence should have precedence of the motion approving the report. The clear issue was raised by the former motion as to whether the Association or any new body was to voice the views of panel practitioners in the future. The question arose in 1914, before the war; it was discussed, and the Association was preferred, and had acted each year since. It was necessary, before approving in detail what the Association had done in the past or instructing it for the future, to settle this outstanding question. If it were decided that the Association was not to continue to receive their confidence, it would be for the Chairman to determine in what way the resolutions on the agenda could be dealt with subsequently.

Dr. Fothergill's amendment giving effect to his proposal, which was seconded by Dr. E. BURRELL (Brighton), was lost.

Dr. BRACKENBURY then proceeded to discuss the report of the Committee. He wished particularly to draw attention to the statement in the report—

In every case where direct instructions were given by the Conference that certain action was to be taken, such instructions have been carried out.

One portion of the report was incomplete—namely, that which dealt with munition areas. At the last Conference a good deal of discussion arose on this, and it was felt by some representatives of such areas that certain action ought to be taken. The difficulties were pointed out, and these difficulties had increased because, with every week, munition areas had become more numerous. After full consideration and consultation with the Commissioners, some eight or nine typical munition areas were selected, and the case was put to them and they were asked whether they desired the Committee to proceed with the matter or not. All replied except one, and only one of those replying wished them to go on with the matter at all. But as soon as the figures for 1916 were completed, certain munition areas felt that those figures disclosed such a case for them that the matter might well be reopened, and accordingly the Committee met certain representatives, received certain propositions, and promised to go to the Commissioners on their behalf. The Committee went to the Commissioners and put the case of these munition areas as strongly as possible. But no satisfactory solution was arrived at, and for these reasons: first, almost the whole country was at the present time a munition area, and it was recognized by everybody that the only possible solution of the matter was to take away money from those areas which were not munition areas and give it to those which were, and this created great difficulties; in the second place, many counties were not homogeneous munition areas, and the question would arise in a composite area such as a large county how the money should be distributed. Further, in munition areas there were practitioners whose whole panel might consist of domestic servants. How could one distinguish equitably between the man who was affected by the munition question and the man who, though living in the same area, was not? Candidly, there was no satisfactory solution of the problem. The speaker went on to give some figures relating to the diminution of money (and consequently of insured persons) in the year 1916 as compared with 1914. Taking the country as a whole, there had been a diminution of 12.2 per cent. in the number of insured persons, and correspondingly in the amount of money available, due to enlistments into the army being greater than the new influx of munition workers, and this diminution of 12.2 per cent. included, of course, munition areas. Taking seven typical munition areas, the alteration, as compared with the -12.2 per cent. for the country as a whole, was respectively -5.4, -6.4, -9, -6.5, -3.9, -7.9, -9.3 per cent. Therefore, the present

system was not entirely inequitable so far as munition areas were concerned, because the diminution was distinctly less in these typical areas than for the whole kingdom. One could take areas, such as Newcastle-on-Tyne, which did seem to present a case for special treatment; but this must be at the expense of other areas. It was not considered desirable by the Committee to pursue the matter further.

Turning to the question of discharged disabled sailors and soldiers, Dr. Brackenbury said that there had to be considered first of all the question of the policy underlying the agreement, then the character of the agreement itself, and finally the procedure by which the agreement was arrived at. The Insurance Acts Committee was not responsible for the policy underlying this agreement. It might or might not be a right policy, but it was laid down in the minutes of the last Conference, and the Committee considered itself bound by those resolutions. Personally he thought that anything which led to a complication of machinery was a mistake; anything which led to a departure from the capitation system was a mistake; but that was not the question before them. The Conference last year was so unanimous in its determination that it would not hear what he had to say on the subject. It was not open to anybody that day to condemn the Committee for not adopting a different policy. The resolutions of last year stood, representing, perhaps not the best policy, but at all events a definite, intelligible, and logical policy, which had to be followed by the Insurance Acts Committee. Those resolutions involved the separation of the treatment of discharged disabled sailors and soldiers from that of the ordinary classes of insured persons. They involved the setting aside of additional money for that separated class of men, the possibility of men not on the panel attending discharged men, and the arrangement of a scheme of payment to obtain these ends between the British Medical Association and the Commissioners and Treasury. Any criticisms based on the plea that the Committee ought to have acted on a different policy were not germane to the present discussion. With regard to the agreement itself, its essential part was this: that whatever the practitioner was paid for the ordinary insured person, adequate or inadequate, if he attended that insured person five times in the course of the year—as he probably did—and had to attend the discharged disabled man twenty times in the course of the year, he would receive four times for the discharged disabled man what he got for the ordinary insured person. He submitted that this was a most satisfactory state of affairs, given the policy underlying it. The deduction was made from the central pool of such amounts as would have gone into it—no others—in respect to these discharged disabled men; with reference to discharged disabled men for whom no contributions would have gone into the pool, proper allotments and calculations had been made so as to ensure the same amount going into the central pool for them, and if the central pool did not meet these bills in full, the extra amount of money would be given by the Treasury in order that they might be met. He submitted that this was a very satisfactory agreement if the policy of separating these men as a class were to be adopted at all. It was still possible to repudiate it. It was no advantage to the Insurance Commissioners or to the Treasury that that agreement should hold. The authorities were prepared to go back and let these men stand on the ordinary 9s. basis as they did before. But what in that case became of the panel practitioners' contention that these men would require more attendance than the average insured person, and that for such attendance they ought to receive more payment?

With regard to the procedure by which the regulations had been brought to the notice of Panel Committees, let him give just the salient dates. On June 8th a circular was sent out to every insurance practitioner telling him that negotiations on this point were in progress so that he might keep his eyes open for any pronouncement to be made sooner or later as to their nature. In the SUPPLEMENT of June 16th the detailed proposals which were emerging from those negotiations were published, and amongst other things it was stated that it had not been found possible to give data for definite calculations on a capitation basis and that therefore they would have to accept the attendance basis if they were to calculate any proper amount of extra remuneration for the additional attendance required. On

July 7th, through the same channel, the documents and results obtained up to that time were published and a detailed account was given of the stages of action which the Committee had taken. On August 4th the detailed result of the negotiations was sent to every Panel Committee. On September 1st a further letter was sent out stating that the regulations now being issued did, in the Committee's opinion, embody the agreement which had been entered into. Up to September 1st no objection from any Panel Committee or from any individual panel practitioner had been received at the offices of the Insurance Acts Committee. What was the Committee to do? Up to September 1st the only communications on the subject—and those in fair abundance—were from men and from committees who expressed no objection to the proposals for the new regulations but asked when they were to come in force. Imperfect as the procedure might have been, undesirable as it might be in the future to accept non-complaint as meaning absence of complaint, what could the Committee do other than that which they had done? Not the slightest indication was forthcoming that anybody objected. He thought that if a broad view of the matter were taken, it would be accepted that the Committee had done very well and had acted quite properly throughout. (Loud applause.)

Dr. J. RATCLIFF-GAYLARD (Committee) moved that, having heard the statement of the Chairman of the Insurance Acts Committee, the Conference proceed immediately to the resolution of confidence.

Dr. H. F. OLDHAM (Lancashire) seconded. Before criticizing the Committee let them decide who was to manage their affairs in the future.

Dr. H. J. CARDALE (London) objected that, if a fair decision were to be come to, not only Dr. Brackenbury must be heard, but also those who had any criticisms to make on the report.

Dr. Ratcliff-Gaylard's motion was lost, and the report was considered *seriatim*.

Representation at Future Conferences.

Dr. H. G. DAIN (Birmingham) moved that the representation of Panel Committees at future Conferences should bear relation to the number of insured persons in the area as well as the number of practitioners on the panel, and that in any formal division both these factors should be taken into account by giving the votes a proportionate value. At present one area might have twice or three times as many insured persons as another area and yet only have the same number of panel practitioners. Every vote at that Conference should have a value representing the insurance interest in the given area.

Dr. T. WOOD LOCKET (Wiltshire) expressed strong opposition to the proposal. It would mean that the proportional interest of rural practitioners would be swamped at once. He did not think that his colleagues in town areas realized the value of the rural vote. They would discover it if there were such a thing as a fight with the Government on any issue. In an urban area it might be possible for the Government to develop an alternative scheme of its own, but that would not be possible in the rural areas.

The rider was lost by a large majority.

Dr. J. GOFF (Lanark) had an amendment objecting to the procedure by which the fifteen direct representatives on the Insurance Acts Committee were only nominated by the Local Medical and Panel Committees, and claiming that they should be elected by the unvetted vote of those committees.

The CHAIRMAN said that this was purely a technical matter. There could never be any question of the veto of the nominations. The procedure of nomination as distinct from direct election was made in order to meet the by-laws of the British Medical Association.

The amendment was lost.

Rural Practitioners.

Dr. R. A. WELSH (Northumberland) moved:

That in future in any negotiations that may take place between the Insurance Acts Committee and the Insurance Commissioners (including the Ministry of Public Health), it is to be clearly understood that the status of the rural and agricultural practices shall be considered as distinct from the industrial or city practices, and that measures shall be devised and taken whereby on every official committee rural practices shall be proportionately and duly represented by rural practitioners.

He said that the rural practitioner was constantly outvoted at the Panel Committees, and that the standing representation which rural practitioners had now on the Insurance Acts Committee and its Subcommittee was only secured after much protest and was still inadequate. The Scottish Insurance Acts Subcommittee recognized the principle, and Wales had its rural representative. It was regrettable that no rural doctors would be on the Advisory Committee.

Dr. T. CUMING ASKIN (Suffolk, E.) said that a Rural Subcommittee of the Insurance Acts Committee was elected last year, but unfortunately the rest of them did not know, except from the references in the Interim Report on Insurance Practice, what that subcommittee had done.

Dr. BRACKENBURY believed that the Conference would desire to see an increased representation of rural practitioners on bodies which had to deal with matters affecting rural practice. But the amendment in its present form was impracticable; it was a question of machinery. He could assure the Conference that the Rural Subcommittee, so far as it went at present, was working very well; it had been asked to consider every rural interest which had come before the Insurance Acts Committee, and although it was not yet possible to set out the results, the work was bearing fruit, and would be very obvious by the time the Conference met again. With reference to the absence of a rural practitioner from the Advisory Committee, the Insurance Acts Committee felt that the action taken by Sir Edwin Cornwall was ill advised. Sir Edwin had himself asked them to select one member to represent the rural practices, but when the Committee was appointed neither of the two names they had suggested appeared upon it. The Insurance Acts Committee did not intend to sit down under that.

Dr. R. HARDING (Radnor and Brecon) and Dr. G. J. B. CANDLER-HOPE (Yorkshire, N.R.) gave illustrations of the special difficulties of rural practitioners, and the latter asked whether the Rural Subcommittee was ever consulted before the terms of the new regulations were accepted. One item of the regulations exclusively affected the rural practitioners—that relating to mileage.

Dr. BRACKENBURY said that the Rural Subcommittee was not specially consulted on the matter of discharged disabled sailors and soldiers.

Dr. WELSH, the mover of the amendment, said that the complaint was that rural practice differed so entirely from industrial and city practice that men engaged in the latter did not appreciate the position of the rural practitioner.

The amendment was carried, and the CHAIRMAN said it would become the duty of the Insurance Acts Committee to consider how it could be carried into effect.

DISCHARGED DISABLED SAILORS AND SOLDIERS.

Dr. G. G. GENGE (Croydon) moved:

That this Conference regrets that the Insurance Acts Committee consented to payment for disabled service men being made at a dividend rate, which is a dissatisfying and irritating method of payment. The Conference instructs the Insurance Acts Committee that panel practitioners will not readily accept this method of payment for any further extensions of insurance work.

He said that in agreeing to payment at a dividend rate for attendance on disabled service men the Insurance Acts Committee lost a golden opportunity of breaking with the evil precedents that bound them and striking a blow for freedom. The members of the Committee appeared to be ever anxious to find favour with the Commissioners, instead of always busying themselves in seeking a favourable ground for fighting. Where could be found a more favourable ground for fighting than this? Their worst enemies could not contend that half a crown a visit was an unreasonable fee for attendance on disabled men, yet this Committee, without consulting the Panel Committees, agreed to the unhappy dividend rate of payment by attendance. Granted that it might be 95 per cent., granted an Exchequer grant, these only strengthened the argument that they should have stood out for a fair and square and definite scale of payment, or, better still, for an increased capitation fee, threatening that if this were not granted for this special class the whole question of inadequate pay would at once be raised and fought to an issue. As for the Commissioners, it must be assumed that they were honest men; yet, even so, they should have taken care to be above suspicion. If he tried to do business

with his greengrocer after their manner, sending him a memorandum instead of payment in full, he would not only lose his greengrocer's respect, but would fail to get his vegetables. Instead of sitting in sackcloth and ashes in the face of all this, the inimitable Chairman of the Insurance Acts Committee came forth boasting of his prowess and success, and telling them, "It remains for practitioners to give adequate attendance to these disabled men and to keep such accounts as will enable them to be paid," etc. In truth, much more remained.

Dr. BRACKENBURY replied that the Insurance Acts Committee was not quite so simple as Croydon seemed to think. He admitted the impeachment that they did not enter into negotiations with the Commissioners with the main object of finding opportunity for a fight. They went presenting a case on behalf of panel practitioners and committees which they believed would bear investigation on its merits. On this particular matter the main thing they had to put forward was this—that whatever the insurance rate of payment might be, they would receive amounts proportional to the extra attention these men would require. Whatever the unit was, they would receive so many units for the extra attendance given. The unit was a calculable insurance fee which came so near to what was set out in the schedule that they actually did put it in so many words to the Commissioners and the Treasury, that instead of this insurance fee which calculated out accurately at a fraction over 2s. 4½d., they should take the schedule figure; but the Treasury did not see their way to depart from the logical position, and therefore the fee unit had to be accepted.

Dr. H. F. OLDHAM (Lancashire) said that it appeared to him that the question at issue was whether they should accept a dividend payment which would be free of criticism, or the full payment of 2s. 6d., in which case the Commissioners or some one else must put up a pricing bureau as had been done in the case of the chemists.

The amendment by Croydon was lost by a considerable majority.

Dr. E. BURCHELL (Brighton) then moved:

That this Conference of Local Medical and Panel Committees is of opinion that the regulations (benefits of invalided seamen and soldiers) and the documents relating thereto do not fully carry out the agreement made by the Commission with the Insurance Acts Committee—

- (a) That all accounts rendered shall be paid in full;
- (b) That the income limit of £160 shall apply to all disabled men;
- (c) That the disabled man shall be fully advised that his choice of doctor is in no way limited to a panel doctor.

That it be an instruction to the Insurance Acts Committee forthwith to approach the Insurance (Joint) Commission with a view to obtaining a satisfactory amendment of regulations and documents in the above direction.

With regard to (a), Dr. Burchell said that as the Conference appeared to be satisfied with the rate of payment upon the basis set out in the regulations, it would be waste of time to discuss the matter. The amendment in this particular was based upon a letter which Captain Fothergill had written to the press, and if Captain Fothergill, whose intelligence was keener than the average, had been misled by what had taken place before the Commissioners, it was evidence that the whole proceedings were nebulous. As to (b), his own Panel Committee was uncertain as to whether the point was definitely set out in the regulations; and as to (c), he had with him a card which told the insured person that he might choose any doctor he liked, and that the names of all doctors available would be found on a list at the post office; but the post office list did not contain the name of a single non panel doctor.

Captain FOTHERGILL said that the regulations distinctly stated that the pool for discharged disabled men should be formed by money from the Navy and Army Fund and also from the Medical Benefit Fund. But the discharged disabled man who was not in employment stamped no cards; no contribution was made to the pool on his behalf, and consequently, as there was no money paid into that fund, the chances of getting out any equitable fee for his attendance were diminished. In the case of the temporary residents, 50 per cent. of the doctors had never sent in their accounts, but in this new instance the practitioners would have to send in their accounts, and if they were going to be paid out of this pool, he had not the slightest hesitation in saying that they would not receive 50 per

cent. of their money. It was of no use for the Commissioners to say that the Treasury would pay the account in full. If one went to a court of law on any matter it availed nothing to argue about words which were used in the House of Commons when the legislation was passing; the only thing that mattered was the wording of the Act itself. The pool would only yield 50 per cent., and what real guarantee was there that the Treasury would pay the balance?

Dr. E. H. M. STANCOMBE (Southampton) said it was hopeless for most of them to master the memorandums of the Commissioners and all the complexities of the situation (to which the agenda that day bore witness), and they had no power whatever to instruct the Insurance Acts Committee on a definite course of action. Dr. Brackenbury had said that the Committee had carried out the instructions of the Conference with regard to the new regulations, but he (the speaker) was certain that if the previous Conference did approve of getting more money for this increased work, it did not understand itself to be committed to an arrangement which was governed by a dividend rate, by inflation, and by one thing and another. They might take it that instead of the 2s. 6d. a visit which the *Times* and the *Daily Chronicle* had hailed as the fee paid by a benevolent Government to the poor practitioners, it would be reduced under the first diminution to 2s. 4½d., then to 1s. 9d., and at the present value of money practitioners would be asked to attend patients at what would be virtually less than one shilling a visit. They certainly were not prepared for such a *dénouement* as that when they gave the vote on the previous occasion, and they could not accept Dr. Brackenbury's very naive apology. The speaker admitted that, within its limitations, the Insurance Acts Committee had done the best it could. His contention was not to impute blame to the Committee but to blame panel practitioners because they had not properly organized their own opinions nor had the will to see that those opinions were carried out.

Dr. G. AINSLIE JOHNSTON (Westmorland) said that Captain Fothergill was in error in declaring that the full 9s. was not paid into the general medical pool for every discharged disabled sailor and soldier who was a member of an approved society and was unemployed. It was wrong to say that no payment was made in such cases.

Dr. A. FOSTER (Leicester) asked whether the Insurance Acts Committee, in its interviews with the Commissioners on this matter, entered into any understanding that the sums to be paid at the end of every quarter were to be paid on account. The clerk of his own Insurance Committee had stated that he had instructions to pay 90 per cent. at the end of the quarter.

Dr. JAMES GARDNER (Burnley) said that many of them went away from the last Conference under the impression that the Government intended to found a special fund to pay for the attendance upon these sailors and soldiers, and that the money should not be paid out of the ordinary insurance fund. It appeared to him quite easy for the Treasury, when it discovered what an exceptional amount had to be paid, to call the attention of the Panel Committees to any doctors' accounts which were considered to be excessive. Thus a wide loophole existed whereby their remuneration might be considerably reduced.

Dr. H. W. JACKSON (Middlesbrough) said that they were instructed that prescriptions for sailors and soldiers were not to be marked in any special way, from which it would be gathered that these would be paid for out of the drug fund.

Dr. T. CAMPBELL (Lancashire) thought that the dividend rate was simply put in for the protection of the Commissioners against the possible abuse of the attendance method of payment by reason of unnecessary visits.

Dr. F. COKE (Kent) asked if the meeting was open for a discussion of the working of the central pool.

Dr. BRACKENBURY pointed out that the amendment declared that the regulations did not carry out in certain respects the agreement entered into with the Insurance Acts Committee. But he could assure them that Captain Fothergill was mistaken in this particular instance. The regulations as published were not understandable by the ordinary man without an undue amount of attention to the wording. He doubted whether it was worth the while of any one of them to try and follow the exact wording of the regulations, but those

whose duty it was to make up their minds as to whether or not the agreement into which they entered was in fact embodied in these regulations had come to the conclusion that it was so embodied. It required expert knowledge to make a decision on this point, but as far as the Insurance Acts Committee on the one hand and the Commissioners on the other were concerned, they were convinced that the regulations as issued did in fact carry out *in toto* the agreement, proper or improper, which was entered into by the Insurance Acts Committee. As to the points which, the amendment alleged, were not embodied, the assurance from the Treasury that it would meet the extra payment could not be embodied in regulations issued by the Insurance Commissioners, but the whole Treasury guarantee, he was told, was implicit in these regulations, and, of course, they had the definite letter stating that the Treasury would be responsible for that extra payment. He agreed that there was an ambiguity about the words "paid in full"; the question was at what rate they would be paid in full (laughter). But a given unit of payment would be made for every attendance, however many. That was the interpretation; that was what they asked for when they said that the accounts should be paid in full. If a practitioner attended a disabled soldier every day in the year, the principle held good all the 365 times. There would be no discounting at the end of the year because there was not enough money in the pool to meet the accounts in full. The insurance rates, whatever they were, would be the rates at which their attendances would be paid for, and would be paid in full. The £160 limit for uninsured persons was embodied in the regulations; and as to the third point in the amendment, the name of every non-panel practitioner who wished to take part in the attendance on discharged disabled men had to be put upon a public list which could be seen by any insured person. Therefore, so far as this amendment was concerned, the agreement on the points laid down was embodied in the regulations.

Dr. T. WOOD LOCKET (Wiltshire) pointed out that if some later amendments pressing for an increased and inclusive capitation grant were carried, it would mean the repeal of their acceptance of these regulations.

Dr. GENGE (Croydon) could not see that it was certain they would be paid in full, for the Insurance Commissioners had no power to bind the Treasury.

Dr. G. J. B. CANDLER-HOPE (Yorkshire, N.R.) said that his Committee, while not objecting to the non-panel practitioner coming in, protested against the terms on which he entered being less fettering than those on which the panel practitioner had to work.

Dr. W. J. YOUNG (Cambridgeshire) thought it only right to point out that there were some present who did not share either in the criticism or the abuse which had been levelled at the Insurance Acts Committee.

Dr. BURCHELL, replying to the discussion, assured Dr. Brackenbury that a considerable proportion of them, when they came to read the exact wording, shared Captain Fothergill's misapprehension. He asked how much of the general drug fund was to be paid for out of this special fund into which the sums of 9s. were to be paid.

Dr. BRACKENBURY replied that the drug question was fully discussed between the Commissioners and the Committee. The question was, having made up the pool, how much was to be taken out in payment for medicines? They had to a certain extent to trust the Commissioners in this matter, and the Commissioners had put it into their regulations that not more than a certain fraction and not less than another certain fraction should be taken out of that fund to pay for drugs. Those maximum and minimum amounts were so arranged that they should in no case exceed the ordinary proportions by which the drugs as compared with the medical attendance came out of the Medical Benefit Fund.

The Brighton amendment was lost.

Dr. G. J. B. CANDLER-HOPE (Yorkshire, N.R.) had a further amendment protesting against the terms of payment as inadequate, particularly from the point of view of rural practitioners. He believed there was little chance of the Treasury grant. The Treasury would do its best to get outside this agreement. The injustice to the rural practitioners was specially severe in view of the question of mileage. With the cost of mileage at 6d. a mile, they were asked under this new scheme to go up to three miles without any payment at all.

Dr. HARDING TOMKINS (Essex) urged that the position of rural practitioners required a good deal more consideration than it had had in the past. He referred the Insurance Acts Committee to the army payment for mileage, whereby the practitioner was treated much better than under the proposed schedule. Army Form O 1667 laid down the following payments:

	Day.	Night.
Under one mile	2s. 6d. ...	3s. 6d.
Over one mile and under two miles ...	3s. 0d. ...	4s. 6d.
Over two miles and under three ...	4s. 0d. ...	6s. 6d.
Over three miles and under four ...	5s. 0d. ...	8s. 6d.
Over four miles and under five ...	6s. 0d. ...	10s. 6d.

For greater distances the payment was 1s. for each mile over five in the daytime, and 2s. at night.

An amendment from Essex asking the Committee to take steps to have the arrangements for mileage improved under the scheme was accepted by Dr. Brackenbury and carried; part of Dr. Candler-Hope's amendment went with this, and the other part was withdrawn.

Dr. J. P. WILLIAMS-FREEMAN (Hampshire), in moving another strong amendment refusing acceptance of the mileage allowance, said that he was appalled to hear Dr. Brackenbury admit that the whole of these regulations were settled without consultation with the Rural Practitioners Subcommittee. It must be remembered that the proportion of visits to attendances was much higher in the country than in town, for an invalided man could often walk a short way to the surgery, but not the long distance necessary in country districts. In sparsely populated areas the doctor could not easily work in two or three visits in one round like the urban practitioner. The time of the rural practitioner was as valuable as that of his colleagues in the towns, yet far more of it was consumed in travelling, and the mileage allowance was simply to cover the out-of-pocket expenses. The time spent in transit might be spent in earning fees. The time, therefore, must be paid for in any equitable system of mileage. He found that his actual expenses on motoring his rounds amounted to £253 a year. He travelled 11,000 miles a year, or 30 miles a day, and this worked out at an expense of 5½d. a mile. Petrol was now 3s. 9d. a gallon, an increase of 2s. 3d., and that represented another 1½d. added to the mileage cost. Even if the cost were taken at 6d. a mile, a journey of 5½ miles out and 5½ miles back meant an expenditure of 5s. 6d. On a three years' average he found that he had to travel 4.54 miles for each visit; the cost of this was 2s. 3d., and his time also had to be reckoned in assessing the proper fee. He wondered why the three mile limit was ever adopted by the Insurance Commissioners; it had not been the custom of the profession. The other Government departments had treated the matter more fairly. He reminded the Conference of Sir Rickman Godlee's recent statement that "medical men ought not to be expected to give their services as a charity to persons for whom the State is responsible."

Dr. T. CUMING ASKIN said that his area of East Suffolk strongly disapproved of the mileage fee.

Dr. BRACKENBURY agreed that the mileage allowance for rural practitioners was on a bad basis, and that there must be a radical change in the mileage system. But the Hampshire amendment stated virtually that the regulations could not be accepted without that alteration. Suppose it were carried, and they failed to secure the acquiescence of the Treasury, what would be the position? (A voice: "Fight.") A fight on any question of this kind was a big thing, and the answer to a fight might be the suspension of medical benefit by the Government. That would mean, in the first place, the stoppage of all their insurance incomes as from a given date, and in the next place, it would mean giving the approved societies a free hand to exploit the profession as they chose. It might be wiser to give the negotiating body a little freer hand. Let that body go to the Government with any proposition which could be discussed on its merits, but the members of the Conference should be sure of their stand.

Dr. WILLIAMS-FREEMAN said that he did not wish to commit the profession to a fight on a point which purely affected rural practitioners, but there could hardly be a stronger case of injustice than this. He agreed to delete the words "cannot accept" and "demand," and in its revised form the amendment was carried as follows:

That we strongly object to the mileage allowance offered for attendance on discharged disabled sailors and soldiers, and

press for the same scale of payment as that allowed for attendance on serving soldiers.

Dr. H. J. CARDALE (London) moved an amendment expressing disapproval of the new regulations, and continuing:

And that the Insurance Commissioners be approached in order to obtain the immediate withdrawal of these regulations, and, further, that the panel practitioners be advised to agree to the reinstatement of discharged sailors and soldiers on their lists, and to render all necessary medical attention and treatment at the present capitation rate, pending negotiations with the Insurance Commissioners for a more equitable scheme.

The mover said that they had been told that the arrangements were subject to reconsideration at any time. He hoped to persuade the meeting that there was no time like the present. Criticizing first the method of introduction, he said that his Committee could not admit that the resolutions of the last Conference gave any justification for the action taken by the Insurance Acts Committee. The principle of payment by attendance was introduced, and this was quite contrary to the express desire of the profession. Every Panel Committee in the kingdom, save perhaps two, had accepted the capitation system. The only resolution of the last Conference which bore on that point was one which stated that payment for medical attendance should be on a scale agreed upon between the British Medical Association and the Government. It laid no burden on the Committee's shoulders, and it was most unfortunate that there had been no consultation of the Panel Committees throughout the country prior to the issue of these regulations. A statement made on June 8th that negotiations were in progress was not very enlightening. It was not until August 4th that Panel Committees were communicated with. All panel men did not belong to the British Medical Association, and to those who were not members an announcement made in the *JOURNAL* would not appeal. He understood also that the regulations themselves when completed were accepted on behalf of Panel and Local Medical Committees by the Chairman of the Insurance Acts Committee. That interfered vitally with the statutory rights of Panel Committees, and it gave a colourable excuse to the Commissioners for neglecting to bring Panel Committees into consultation. With regard to the regulations themselves, these were open to criticism on the ground of complicated finance and on the ground of the principle of payment for attendance. Little had yet been said as to the duties thrown upon panel practitioners of checking these attendances. Dr. Cardale also referred to the evident intention of the authorities to make use of the out-patient departments for the treatment of discharged disabled sailors and soldiers. The Army Council had issued to the competent authority instructions in which it was stated that, as a general rule, the cases to which the intended treatment would apply would be those suitable for the out-patient departments of hospitals; not a word was said about the general practitioner. He submitted his amendment with some confidence as a reassertion of the statutory privileges of Panel Committees which had been infringed by the Commissioners.

Dr. BRACKENBURY reiterated that on June 16th certain announcements were made in the *BRITISH MEDICAL JOURNAL*, among them the statement that the only way to secure extra payment seemed inevitably to be by an arrangement on the attendance basis. Yet from June 16th to September 1st the London Panel Committee never said a word. To spring this amendment upon the Conference in this emphatic way was not quite fair towards those who were negotiating these matters. In such affairs they could not have it both ways; they could not have collective bargaining and separate bargaining going on together. If they trusted their central negotiating body to negotiate for them, they could not at the same time claim for themselves complete freedom to negotiate. But if any individual practitioner now said that he did not accept these new regulations as legally binding because he had not been given the requisite notice for altering his agreement, the Commissioners could certainly say to him, "We give you notice from this day that on such a date in the future these regulations will come into force, and if you do not accept them you are at liberty to resign from the panel." The individual insurance practitioner could stand upon his individual legal rights if he cared to do so, but not so the Panel Committee. As a profession,

however, they wanted to be as united as they could, and having found the body which best united them, they should be prepared, whether as individual practitioners or as Panel Committees, to waive their rights as separate negotiators. With regard to Dr. Cardale's last point, it was possible, under the arrangements being made by the Ministry of Pensions, that some of these discharged disabled sailors and soldiers would be diverted into the out-patient departments of hospitals. He did not think it would be a good thing for the nation, but if anybody was to be blamed it must be the staffs of the hospitals.

Dr. LAURISTON SHAW (London) regretted that the mover of the amendment had laid such stress upon the method of introducing the regulations. It was true that there might be a good deal of difference of opinion as to whether the most skilful method was adopted so as to ensure the willing acquiescence of all panel practitioners. Whatever might have been done and done amiss, they were united in a genuine appreciation of the work the Insurance Acts Committee had had to do. He thought the diplomatic method would be for them now to go to the Commissioners and say that, having looked into the regulations, which they were assured were experimental and temporary, they found that some of their views of a year ago were not as well formed as they should have been, and that there were many reasons why it should be possible to reopen this question and come to some more equitable arrangement, both in town and country, which would secure as good treatment for the discharged disabled sailor and soldier as the present system. The present arrangements contravened the principle for which he had been fighting for many years in the British Medical Association. He was convinced that the capitation system was the ideal one, because it established the principle that every patient had a general practitioner to look after him. But what happened under a scheme of payment for attendance? It became a question of economy; general practitioner treatment began to be subordinated to some other form of treatment which was held to be cheaper, and institutional treatment offered itself. But if these people were drafted to the institutions the general practitioner did not obtain his fees. He believed that 90 per cent. of the panel practitioners were in favour of the capitation basis, and it seemed reasonable that they should go back to the Government and say that in their mature judgement the attendance system could not be satisfactory, and that the present situation supported an unanswerable claim to an increased capitation grant all round.

Dr. E. H. M. STANCOMB (Southampton) supported the amendment, which, he said, provided for an interim period during which the men could obtain all necessary attention and treatment while negotiations were still proceeding. He and those for whom he spoke wanted some little delay in order that they might mature the opinion of the Conference in favour of, perhaps, a uniform capitation fee of 10s.

Dr. J. RATCLIFF-GAYLARD (Committee) said that twelve months ago the profession approached the Commissioners on this subject, and pointed out the additional work which would be necessary, and the desirability of something better than the existing capitation payment. The Commissioners said, in reply, that they did not admit that the additional work would be so great as the profession thought. The profession insisted on a basis of payment by attendance as the only way of testing this question, and the Insurance Acts Committee, in their negotiations, carried out the mandate of the Conference. Now, almost immediately the new regulations were in force the profession declared that they had made a bad bargain and that they would rather go back to capitation payment. If they made a bad bargain they did it with their eyes open. Let them have the courage to stand by it, and see after twelve or eighteen months how it was working out. They could reserve to themselves the right then to go back to the capitation basis if desired.

Captain E. R. FOTHERGILL (Committee) said that not a single suggestion had been put forward for a more equitable scheme. The profession should be willing to produce data honestly prepared on which they could base the claim for just payment. If they said that they would take the capitation basis at 9s. or 10s., a new economic basis might arise, and where would their successors be? They were going to tie their successors to payment of

which they knew nothing, for services of which they knew less. If they accepted a low rate, work badly paid meant work badly done.

Dr. P. V. FRY (Yorkshire, W.R.) thought the scheme ought to be allowed to go forward as an experiment for twelve months.

Dr. CARDALE, replying to the discussion, said he rather gathered that Dr. Brackenbury considered the carrying out of collective bargaining by the Insurance Acts Committee to be a justification for taking away the statutory rights of the Panel Committees. That was a contention they could not accept at all. (Dr. BRACKENBURY: "Hear, hear"). When Dr. Ratcliff-Gaylard said that they had made a bargain, he did not know whether he referred to the Insurance Acts Committee; he could hardly have referred to Panel Committees.

Dr. RATCLIFF-GAYLARD: The profession as a whole.

Dr. CARDALE: Including the Panel Committees?

Dr. RATCLIFF-GAYLARD: The profession as a whole.

Continuing, Dr. CARDALE said that Captain Fothergill had urged that there was no better scheme. But the whole question of a scheme was to be discussed later. He did not propose to touch upon the subject of the data that could be produced from the records of practitioners, but it was obvious that with the alteration in the value of money they had data on that ground alone to justify them in asking for a very large increase in remuneration.

Twenty-one members supported Dr. Cardale in asking for a division, which resulted as follows:

For the London amendment	20
Against	133
Not voting	1

(The figures represent constituencies; several members voting in the majority represented two or more constituencies. Members of the Insurance Acts Committee, unless also representatives, did not vote.)

The further consideration of the Committee's report was then postponed to admit of motions on the co-ordination and central representation of Panel Committees.

CENTRAL REPRESENTATION.

Dr. BRACKENBURY moved:

That this Conference renews its expression of confidence in the Insurance Acts Committee of the British Medical Association as the central negotiating body of the Local Medical and Panel Committees of the country, and authorizes the Insurance Acts Committee to continue to represent their views, in consultation with the Local Medical and Panel Committees, in all negotiations with the Commissioners and other Government and public bodies.

He pointed out that there were certain disabilities about central negotiations in any case, whoever was the central negotiating body. The Insurance Acts Committee as a central negotiating body was in process of evolution, and they had not yet said the final word about its composition and procedure in relation to Panel Committees and their representation. At one time there was no direct representation of Panel Committees upon the Insurance Acts Committee. For the last two years there had been six direct representatives, and last year it was agreed that there should be fifteen—that is, half the elected members; half the members who were not *ex officio*. Only that day they were electing those fifteen members, and yet before the thing which was asked for last year had had a chance of proving itself at all, they were asked to "scrap" the whole body. Next year they might have some improved and enlarged representation of Panel Committees on the Insurance Acts Committee. Let them proceed along those lines of evolution, step by step, so that they could carry the united profession with them, and let them not give up a good thing when they had it, even though it might not be perfect at the best. The Committee contained twenty-nine members, out of its total of thirty-three, who were actually on the panel and doing insurance work, though it was true that some of those were elected by panel practitioners in spite of the fact that they were not actually panel practitioners themselves. It was true that it was a committee of the British Medical Association, but there were advantages in belonging to a body which had a comparatively large amount of money at its disposal and an established organization. Any other body would have to establish its position and also to pay its way. Was it worth while

putting up another body whose financial basis was at present unknown? In asking for renewed confidence in the Insurance Acts Committee, he threw out the suggestion that that Conference might appoint a certain number of representatives, chosen impartially and from all sections, to meet a similar number appointed by the Council of the British Medical Association, and these combined representatives might report to the Representative Body on the one hand, and to the next Panel Conference on the other, as to changes in the composition and procedure of the Insurance Acts Committee which were desirable and possible.

Dr. H. G. COWIE (London) moved as an amendment:

That this Conference, whilst expressing its full appreciation of the efforts of the Insurance Acts Committee on behalf of the profession in the past, is of opinion that the time has now arrived when negotiations affecting the panel service should be carried on with direct representatives of the Panel Committees.

The London Panel Committee, he said, brought forward this amendment in no spirit of hostility to the Insurance Acts Committee, but submitted it with the object of clearing the ground in an attempt to settle the question which had been seriously agitating the panel profession for some time. The question was, How were the special interests of panel practitioners to be best safeguarded and represented? The Insurance Acts Committee was the special machinery ready set up for that object, but they suggested that it was defective, and from its constitution could not efficiently serve the purpose in view. The fact that it had required considerable readjustment from time to time was presumptive evidence that something was wrong, and the further fact that this readjustment was always in one direction gave a strong clue as to the nature of the defective principle in its constitution. That it had seriously broken down in respect to the new regulations must be frankly accepted as a fact ("No"). No apologies would alter that fact (laughter). While recognizing that there had been no lack of good intentions, yet they safely affirmed that with the very best intentions in the world no machinery could be effective unless it was built on a sound principle, and that principle in this case was direct representation. No committee of an outside organization could ever be directly representative of panel interests, for the moment it became completely and directly representative and responsible only to its panel constituents it ceased to be a committee of the organization. The acceptance of the principle of direct representation was all that was asked for in this amendment, but he might be permitted to indicate the lines on which such a principle would work. A Panel Committee was directly representative of the panel interests of its area, and it followed that a body composed of direct representatives of Panel Committees must be the ideal body to represent the special and common interests of the panel profession. Just as Panel Committees were independent, so this new organization must be independent of all others. The Panel Committee of London was fully alive to the fact that panel practitioners had other interests than panel ones, and recognized the need for the closest co-operation with other organizations of the profession, and especially the necessity of using to the full the power and influence of the British Medical Association. Many panel practitioners thought that everything should be done by and through the British Medical Association, but this appeared a somewhat restricted view; and it might be necessary to have a wider outlook when it was realized that insurance work had become a very important factor in the profession, and that an entirely new situation had been created which might of necessity require new organization.

Dr. E. H. M. STANCOCK (Southampton) said that several times during the day he had tried to prepare his colleagues for this proposal by calling attention to the fact that, in spite of what had been said by Dr. Brackenbury, the whole time of the Conference had been spent in discussing disagreements with the British Medical Association. The number of amendments expressing dissatisfaction was really fatal to the contention that the Insurance Acts Committee had the genuine moral support of panel practitioners. The speaker had had considerable experience, ranging from Southampton to Manchester, and he had not yet met a Panel Committee that had any confidence in the British Medical Association—loud cries of "Oh!" and "133 to 20"—as representative of panel interests. He had himself the

utmost confidence in the British Medical Association for the work it had done in the past. It was no question of scrapping the Association and its Insurance Acts Committee. But when one came down to bedrock, and asked, "Are you satisfied with the new regulations?" very many were bound to say that they were not. Much of what had passed that day was mere sentiment. Anything more kindly and fatherly than Dr. Brackenbury he could not imagine. Dr. Brackenbury spoke to his heart and told him what he ought to believe. That attitude of Dr. Brackenbury was the incarnation of the British Medical Association. But those whom the speaker represented wanted a direct opinion in the first place from the Panel Committees, and then the giving of some advice to the British Medical Association.

Dr. F. COKE (Kent) said that in Kent they distrusted the Insurance Acts Committee, and feared if they gave the Committee a new lease of life the marked failure of the past would recur. When the 1917 regulations were discussed with the Commissioners, the birthright of panel practitioners was given away. The Conference, when it met a year ago, put in some mild ideas with regard to alterations, and these were in course of time brought before the Commissioners, but throughout all these negotiations the Committee was apt to be too autocratic, so far as its relation with Panel Committees was concerned.

Dr. A. FOSTER (Leicester) said that it was obvious that the Insurance Acts Committee had done good hard work, and though it might have erred in some respects, it had done its best. It seemed to him that in any combination of Panel Committees they must have something in the nature of an executive, and for practical purposes the Insurance Acts Committee was their executive. He reminded them of Euclid's maxim, that the whole is greater than the part. The panel practitioners were simply a part of the whole, and even individually the panel work of a practitioner was only a part of his practice, and surely the panel interests ought not to be detached from the interests of the whole profession. An Association of Panel Committees was a fascinating idea, but still his Committee, on looking into the matter, felt that it was better to continue under the wing of the British Medical Association. The Association had a fair progeny, and if, like the old woman of the nursery rhyme, she had so many children she didn't know what to do, the panel service was the youngest of her children, and perhaps might find favour on that account.

Dr. G. G. GENGE (Croydon) said that his Committee felt that, however much the Insurance Acts Committee was open to criticism, it was to be supported and voted for as a negotiating body.

Dr. H. G. DAIN (Birmingham) said that his Committee emphatically supported the Insurance Acts Committee. He pointed out the danger of splitting at the present time. To have two separate bodies during the period of reconstruction which would follow the end of the war would simply give the practitioners over hand and foot to the enemy, who would be able to impose its own terms.

Dr. G. AINSLIE JOHNSTON (Westmorland) and Dr. J. L. SPEIRS (Gateshead) said that their Committees supported the resolution of confidence, the latter declaring, in answer to a statement made previously, that Panel Committees did not know their own minds, that the Gateshead Committee had given him definite instructions on this one point alone, on which it was unanimous.

Dr. J. P. WILLIAMS-FREEMAN (Hampshire) said that his Committee did not know its own mind. It did not approve of the action or inaction of the Insurance Acts Committee over the mileage question, but it was not prepared at the present moment to take the panel representation out of the Committee's hands. He would suggest, however, that there was ample room for this Association of Panel Committees to help the Insurance Acts Committee by collecting material and having local meetings and generally preparing the ground for greater co-operation. He pleaded also for more communication between the Insurance Acts Committee and Panel Committees before the former committed itself to any definite action.

Dr. H. J. CARDALE (London) said that there was no desire to set up any rival body to the British Medical Association. The Association consisted of a number of individual members whose interests it looked after. The proposed Association of Panel Committees was merely a co-ordination of the existing statutory Panel Committees

throughout the country, which he believed would be of the greatest assistance to the British Medical Association in its work on behalf of the profession. He understood from a statement in the *BRITISH MEDICAL JOURNAL* that about ten thousand panel practitioners belonged to the British Medical Association. Why, then, did any fear arise with regard to this co-ordination? for it was obvious that these ten thousand members of the Association would be the controlling force on their respective committees, and could send representatives to carry out their views. But it was hopeless to govern without the consent of the governed, and a considerable number of men did not belong to the Association, while a certain number were hostile. These men always gave trouble in all negotiations. An Association of Panel Committees would stand on a different footing because its membership would be, not individual, but representative of committees. There would not be that residue of non-panel interests which arose in the case of the British Medical Association.

Major D. F. TODD (Durham) referred to the model scheme for the federation of Local Medical and Panel Committees, which was framed before the war as a result of a conference held in that room. Unfortunately the war had suspended the project, but to-day, while that scheme for federation was still in existence, one of the measures which they strongly favoured three or four years ago was in course of adoption—namely, the selection by that Conference of a number of direct representatives on the Committee. Having advanced at that rate it was not impossible that the future would see the whole of the Insurance Acts Committee elected from that Conference with the exception of the *ex officio* members of the British Medical Association. The weakness of the British Medical Association was in its constitution. The constitution was on very democratic lines, but the democracy in this connexion was a pitfall, for the Conference was governed by the Representative Meeting, and there was also the Council. The suggestion thrown out by Dr. Brackenbury that some form of conference between a few representatives of the present meeting and a few representatives of the Association was of great value. Unless they were prepared to close up their ranks and become a solid body they were in for a bad time.

Dr. W. R. HADWEN (Gloucester) said that his Committee was most anxious that there should be nothing like antagonism to the Insurance Acts Committee on the part of the new association, and in his view this latter body did not set up to monopolize the position of the Insurance Acts Committee in the matter of negotiations with the Commissioners.

Dr. BRACKENBURY said that the position of the Insurance Acts Committee was not exactly what had been described by Major Todd. It was a more or less independent committee of the British Medical Association. It had power under its terms of reference to deal with all matters which arose in connexion with the profession under the Insurance Acts. It reported through the Council to the Representative Body.

Major TODD: Could not the Council repudiate the action of the Insurance Acts Committee?

Dr. BRACKENBURY replied that the Council could say that it disagreed with the action of the Committee. What the Council could do, if dissatisfied, would be to turn out its representatives. In the case of the Insurance Acts Committee there was not quite so much difficulty in getting things done quickly as was sometimes said to be the case with other committees of the British Medical Association. If, however, a new Association of Panel Committees were formed and it became, as one of its supporters had stated, and as a literal reading of the amendment implied, one of the duties of the Insurance Acts Committee to negotiate *with* that body, the machinery was being complicated and not simplified.

Dr. COWIE said that the meaning of the amendment was that negotiations should be carried on *by* direct representatives, not *with* them.

Dr. BRACKENBURY said that, such being the case, the Conference had to choose between a division of forces or a reform of the existing Committee. Whatever other association was put up, it would result in a division of forces.

The CHAIRMAN, appealed to by Major TODD, said that, whatever the strict letter of the by-laws, he did not see

that the Council could really interfere with any action that the Insurance Acts Committee decided upon.

Captain FOTHERGILL said that as the years had gone on the Insurance Acts Committee, like the British Constitution, had greatly developed. They had built on a solid foundation from the beginning. The suggestion by some in that Conference that the Insurance Act was for the panel alone implied a limitation of outlook. The whole of the medical profession and the whole of the British public would ultimately be affected by the introduction of National Insurance in 1911. But the Association had realized this, and had gripped with a tight hand anything and everything that was done under the Insurance Acts. Although for the time being the panel doctor was the fundamental party in the contract, his interests were only a part of the developing movement, and in the future the sanitarian and every other kind of doctor would find his fortunes involved in it. If the new association materialized it should be for the purpose of co-operating with or "gingering" the existing body. By standing by the British Medical Association and putting their energies into it, they would do good for themselves and leave a legacy of good for their successors.

Dr. COWIE, in replying, reminded those present that they were there, not as members of the British Medical Association, but as delegates—(Voices: "Representatives")—from Panel Committees. All that he and his friends proposed was what they thought would be a better collective body for this particular purpose than the British Medical Association. They were not attacking the British Medical Association. Some of them had higher ideals for that Association than had their opponents on this question. They wished to place the Association on a platform above the minor matters which might rightly concern any specialized body. It was not splitting the profession; it was organizing the profession.

On a vote being taken, the number of members supporting the mover of the amendment in his request for a formal division was insufficient, but the Chairman consented to count the hands, and there resulted:

For the amendment	16
Against	113

The CHAIRMAN pointed out that several members in the majority represented two or more constituencies.

Dr. MARTIN CUTHBERT (Shropshire) moved the addition to the resolution of confidence:

That this Conference strongly deprecates the division of forces brought about by the creation of new bodies as tending seriously to weaken the forces of the profession.

Dr. LACRISTON SHAW (London) opposed this amendment. He was convinced that a great body like the British Medical Association could not find out all individual and sectional points of view, and it was an actual advantage to the Association to encourage the development of other special bodies, such, for instance, as an association of consulting physicians and surgeons, to focus the views of a particular section and also to educate the members of that section as to its right position.

Dr. HARDING TOMKINS (Essex) said that it seemed possible that some part of the reason why the new Association of Panel Committees was held in certain quarters to be inimical to the British Medical Association was because the word "association" was used instead of "profession."

Dr. A. E. LARKING (Buckinghamshire) said that he did not see why the British Medical Association should finance and look after the interests of men who did not belong to it. He thought that the federation scheme described by Major Todd should be resuscitated.

Dr. F. COKE (Kent) said that the Association of Panel Committees had actually been formed, and he prophesied that it would hold eventually a considerable place in the profession.

The additional words were put as an amendment and carried.

Dr. W. HODGSON (Cheshire) moved an amendment recognizing the machinery of the Insurance Acts Committee as the central negotiating agency of Local Medical and Panel Committees, and authorizing the Committee to continue to represent those bodies, after consultation with them, in negotiations with the Commissioners and others. He said that his Committee was very much afraid of the formation of a body which might exercise the functions of a Government bureau. They wanted to look to the

Association as a central negotiating agency, but not to exclude Panel Committees from the right of making particular representations, if they felt impelled to make them, to the Commissioners. If the main resolution proposed by Dr. Brackenbury were carried it would practically exclude the moral right of any Panel Committee so to do.

The CHAIRMAN pointed out that it was impossible for the Insurance Acts Committee or any other to deprive these bodies of their statutory right, but if they wanted a common opinion expressed, or an opinion in which a number of bodies concurred, there must be a body to co-ordinate those opinions and to express them. He thought that perhaps Dr. Brackenbury would substitute "central negotiations" for "all negotiations" in his motion.

The Cheshire amendment was by leave withdrawn.

Dr. BRACKENBURY, replying on the whole discussion, said that he failed to see how any newly formed association could have any better means of gathering information from and co-ordinating the opinions of Panel Committees than the Insurance Acts Committee.

The motion renewing the expression of confidence and incorporating the addition proposed by Shropshire was then put to the meeting and carried by a very large majority. The word "central" was substituted for "all," as suggested by the Chairman.

Dr. G. G. GENGE (Croydon) and Dr. HARDING TOMKINS (Essex) moved and seconded a rider appointing six members of the Conference to meet representatives of the Council in order to consider and report upon any desirable and possible changes in the composition and procedure of the Insurance Acts Committee.

Dr. H. J. CARDALE suggested that an invitation be extended to other bodies to take part in such a conference.

Captain FOTHERGILL thought such a procedure a work of supererogation in view of the fifteen new members from their midst who would go upon the Insurance Acts Committee that day; and

Dr. P. MACDONALD (York) considered that such a consultation would be futile. The new Association of Panel Committees would be quite willing to confer with the Insurance Acts Committee to see how best to co-ordinate the forces of the profession.

In view of these expressions of opinion the rider was withdrawn, and in reply to other suggestions,

Dr. BRACKENBURY said that if it seemed likely that any good could come out of such a conference the Insurance Acts Committee would have no hesitation in calling or taking part in one.

The CHAIRMAN said that it was far better to leave the matter open, and to allow of an informal meeting if desired.

The Conference then returned to the consideration of the report of the Insurance Acts Committee.

Supply of Data to Panel Committees.

Dr. R. A. WELSH (Northumberland) said that in his area there was a feeling that the doctors as a whole did not receive the full total to which their area was entitled. Not only did they remain unsatisfied that the Insurance Committee had obtained for the area the amount which it should have received, but many individual doctors were not satisfied with the amounts given by the Insurance Committee, and could not understand how their lists were adjusted. The rural doctors in Northumberland got less than 6s. a head for attendance on an insured person and 1s. for drugs, and the county enjoyed the distinction of being the last in England to settle up for 1914-15. He moved that in the event of any such dissatisfaction the Panel Committee should have the right to demand an independent inquiry with full access to all papers, correspondence, and accounts relating to the matter in the hands of the Insurance Committee.

One or two members described the procedure in their own counties, and one suggested that an independent auditor should be authorized to go into the accounts.

Dr. BRACKENBURY was a little doubtful as to whether it would be possible to insist upon the disclosure by an Insurance Committee of all papers and correspondence relating to a particular matter. Perhaps the Northumberland Committee might be content with the powers it already possessed of receiving all information as to accounts for the area.

Dr. WELSH withdrew his amendment on the understanding that the matter would be placed before the

Insurance Acts Committee, who would get legal advice as to the limits of action.

The Advisory Committee.

Dr. I. G. MODLIN (Sunderland) moved an amendment protesting against the omission by the Insurance Acts Committee to recommend the name of a representative of the practitioners of the North of England as a member of the Advisory Committee. He said that between Leicester and Edinburgh there was not a single representative. Of the twelve originally suggested not one represented the North of England; of the additional seven there were two from Lancashire and two from Yorkshire but none were appointed; and while the South of England had two representatives, London two, Scotland two, Ireland one, Wales two, and the Midlands four, yet that large district embracing Northumberland, Durham, Yorkshire, and Lancashire was left without a single representative.

Dr. BRACKENBURY protested that the fault was not that of the Insurance Acts Committee. The appointments were entirely in the hands of Sir Edwin Cornwall, who, after pressure from the Committee, accepted nominations from local committees to the number of fifteen, though he limited them to eight at first. The Committee maintained that the different kinds of practice and of practising areas could not be represented by less than eighteen to twenty-one nominations. The course adopted was to nominate those persons who had received the greatest number of nominations from Panel Committees. Sunderland would have had the Committee use its own discretion, but this would have involved condemnation by the Conference. It was unfortunate that so large a district had no representative, and it was a thing to be remedied if possible.

Major D. F. TODD (Durham) thought the Committee had shown weakness. This was a case in which geographical representation should have come in. He did not agree that the Insurance Acts Committee was tied down; the fact was that it had not taken the different parts of the country sufficiently into consideration.

Dr. P. MACDONALD (York) said that this incident accentuated the need for proper organization of the profession.

The CHAIRMAN read the letter sent by the Committee to the Panel Committees in which it was stated that the Committee would be guided by the preferences shown.

Dr. A. FORBES (Sheffield) supported the amendment, and said that it was true that the circulars were sent out, but the committees had no means of communicating with others in the same group.

Dr. RATCLIFF-GAYLARD (Committee) said that if the committees in the North of England had had the matter at heart and only seven or eight of them had nominated one man, that man would probably have been included on the Advisory Committee.

Dr. STANCOMB (Southampton) thought that this side issue again illustrated the need for a new association.

Dr. H. F. OLDHAM (Lancashire) suggested that the amendment be revised so that it simply protested against the omission from the Advisory Committee of any representative from the North of England, and Dr. MODLIN accepting that suggestion, the amendment was carried in that revised form.

Dr. J. STEED (Herefordshire) had an amendment similarly protesting against the non-inclusion of a rural practitioner on the Advisory Committee. Two rural practitioners were nominated, one of them by a very large number of committees, and his Committee considered it regrettable that both should have been passed over.

Dr. E. LEWYS-LLOYD (Merionethshire) thought it incorrect to say that there was no representative of rural practice on the Advisory Committee. Dr. E. O. Price of Bangor, who was among those chosen, was actually a rural practitioner, covering a very wide area.

Dr. BRACKENBURY said that Dr. Price was appointed by Sir Edwin Cornwall from nominations taken from some other source than the Insurance Acts Committee.

Dr. STEED said that his Committee considered that a practitioner living in a town of 10,000 or 12,000 people could not be described as a rural practitioner.

The amendment was lost, whereupon Dr. CUMING ASKIN said that that was an instance of the treatment which the rural practitioner received from the Conference; but the CHAIRMAN, as a rural practitioner himself, demurred.

Dr. LEWYS-LLOYD moved, on behalf of Cardiff, a resolution of protest against the non-acceptance of two nominees, Dr. Treasure and Dr. Harding, as representatives on the Advisory Committee, and this was agreed to.

At this point, reverting to the discussion on the treatment of discharged disabled sailors and soldiers,

The CHAIRMAN moved, on behalf of Coventry, and it was agreed:

That this Conference, whilst agreeing that the Insurance Acts Committee, in view of the decision of last year's Conference, made as good an experimental arrangement as was possible with regard to the treatment of disabled soldiers and sailors, is distinctly of the opinion that such an arrangement will be detrimental to the financial interests of the profession unless a most careful account be kept and rendered by each individual medical practitioner of all services rendered, and that it be an urgent request from this Conference that each panel area instructs each member of its Committee in county areas to call a meeting in their respective districts to explain fully to their fellow practitioners the importance of the arrangement.

Medical Cards.

Dr. H. G. DAIN (Birmingham) moved:

That an insured person who has not selected a doctor or who has removed into another area is only entitled to medical benefit on production of the medical card; that fees charged in absence of such medical cards should not be returned; and that all medical cards should bear the date of issue, and if not presented to doctor for signature within twelve months, should be re-dated by the issuing committee.

He said that the position as it stood at present entailed the bringing of a number of cases before the Medical Service Subcommittee, and it was difficult to get the lay members to understand the intricacies of the question. The effect of the present ruling of the Commissioners was to make for slackness all round. The resolution was not intended to apply to people who had selected a doctor. The twelve months allowed before re-dating might seem a long period, but he was told that shorter periods would give rise to great administrative difficulties.

Dr. A. FORBES (Sheffield) supported the proposition, which had a distinct bearing on munition areas. On the general question of munition areas he desired to say no more than that Sheffield was dissatisfied with what was done on their behalf by the Insurance Acts Committee.

Dr. F. E. DANIEL (Barrow) supported the resolution, which, he said, went to the root of the matter. There were about five or six thousand insured persons in Barrow who had never chosen a doctor. As to the precise method of getting them to choose a doctor, he was not quite sure. He would like the Insurance Acts Committee to do its best to devise some scheme for overcoming the difficulty, either by penalizing the insured person, or—which would be better—penalizing the approved societies, with whom the fault lay quite as much as with the insured person.

Dr. BRACKENBURY said there was no need to press it upon the Insurance Acts Committee that it should devote its attention to this matter. They all realized the situation and knew it had to be met, and that the onus of proof should be on the insured person. He urged that the various suggestions should be referred to the Insurance Acts Committee rather than that the Birmingham motion, which expressed a preference for a particular method, should be adopted.

Dr. C. H. PANTING (Essex) said that his Committee had formulated an amendment on the subject which simply threw upon the Insurance Acts Committee the task of taking steps to find the best method of making insured persons present their medical cards to a panel practitioner immediately they received them. In his area they had at the present moment 30,000 "dud" cards on their register which they did not get paid for, and this was one of the causes of inflation. By removal from the district and subsequent return, together with the loss of cards and the issue of duplicates, inflated lists resulted.

Dr. G. J. B. CANDLER-HOPE (Yorkshire, N.R.) called attention to a rural matter in connexion with the medical card. When an insured person got his medical card he remained unallotted until the beginning of the next quarter. If he came to a rural practitioner for treatment in the interval, the practitioner had to supply him with medicine, though technically he was not on his list until the beginning of the following quarter, so that the practitioner got nothing for the medicines. In the towns, on the other hand, the prescription was sent to the chemist, who got paid for it.

Dr. G. AINSLIE JOHNSTON (Westmorland) gave some account of how the Lake District was affected by the brief stay of a number of insured persons who subsequently removed and transferred to doctors in other districts. He moved a rider embodying proposals to improve matters.

It was agreed that the suggestions contained in all the amendments on this subject should be referred to the Insurance Acts Committee.

The Conference then formally approved the report of the Insurance Acts Committee.

COLLECTIVE BARGAINING.

Dr. BRACKENBURY proposed a motion approving the scheme for collective bargaining as submitted by the Committee, and pledging the Panel Committees to carry it into effect. He said the scheme had now been set out in more definite detail, and one or two matters were settled which were left open on the previous occasion.

Dr. F. COKE (Kent) could not see where the two months' notice came in, and also criticized the scheme on other grounds.

Dr. E. H. M. STANCOMB (Southampton) urged that nothing short of trade union powers could suffice to organize the profession for collective bargaining. After those brief two months, the Association as it stood would have no power to use its central authority, its office and staff, for the purpose of advising any one of them to break or vary the contract at that time in existence. And not two months but six or twelve months might be necessary in order to carry out collective bargaining, during the whole of which time an association must be in existence to protect the profession.

Dr. C. J. PALMER (Nottinghamshire) moved that the scheme be referred back to the Insurance Acts Committee for further consideration, and this was seconded by Dr. E. BURCHELL (Brighton).

Dr. LAURISTON SHAW (London) said that the scheme was misnamed collective bargaining; it was really collective declaration of war against the Commissioners. What they wanted in any real system of collective bargaining was to know how they were to carry the war on after it had been declared, and also what machinery there was to ensure peace—that is, the withdrawal of resignations when the majority of practitioners wished that course to be adopted. The scheme should go further than the mere sending in of resignations.

Dr. F. E. DANIEL (Barrow-in-Furness) said that some of them thought that they had no right to take a drastic step of this kind during the war and in the absence of their fellows.

Dr. BRACKENBURY agreed that it should be a serious extremity which indicated such a course at the present time, or, for that matter, at any time; but that consideration should not deviate them from the purpose of having a scheme ready for use in emergency during the next twelve or eighteen months. The matter had been under their consideration for some years; it was accepted in some detail last year, and therefore he deprecated the motion to refer it back. Although Dr. Shaw's remarks were of extreme importance it did not seem to follow that this scheme, so far as it went, should not be accepted. It was true that they did not deal with the details of the situation which would arise after all the resignations had been sent in, but he thought that could be dealt with very well as a supplementary to the present subject. He went on to explain certain features of the scheme.

The amendment to refer back the scheme was lost, and Dr. BRACKENBURY accepted an amendment by Brighton instructing the Committee to take all possible steps to obtain the adherence of all the Panel and Local Medical Committees with a pledge to support the scheme loyally should it be necessary to carry it into effect; and another by Herefordshire, the intention of which was that the Insurance Acts Committee should consult with Panel Committees before agreeing to any proposals for alteration of regulations. With regard to this last, Dr. Brackenbury said that he understood it to refer to proposals affecting the operation of the regulations and not necessarily to the verbal regulations themselves. Circumstances might conceivably arise in which it would not be possible to have the actual wording of the regulations themselves submitted to Panel Committees.

Dr. COKE (Kent) and Dr. B. A. RICHMOND (London) protested against this last interpretation, and Dr. BRACKENBURY

further explained that the normal procedure would be, wherever possible, to have the actual wording of the regulations brought before the Committees, but in some remote contingency it might become necessary for the Committees to trust somebody to see that alterations which had been agreed upon were duly embodied.

The CHAIRMAN (speaking as the Representative of Somerset) said that this matter went down to the root of collective bargaining. Occasions might arise in which the procedure had to be pressed up so closely that it was necessary for somebody to decide at once on behalf of the panel service in general, and in that case it would be not only legitimate but absolutely necessary to repose a certain amount of trust in this central body.

Dr. COKE asked whether the Insurance Acts Committee did or did not ask Panel Committees to give it a mandate.

Dr. H. G. COWIE (London) said that it was absolutely impossible for any statutory body to depute any of its statutory privileges to any one else.

Dr. E. H. M. STANCOMB (Southampton) said that the procedure of delegating their powers, which Panel Committees had been content to adopt, meant a continual belittling and dwindling away of their proper functions as statutory bodies.

Dr. H. F. OLDHAM (Lancashire) said that the last speaker and those who thought with him apparently saw no danger or wrong in handing over the rights of Panel Committees to the particular organization which they persistently recommended to the Conference, but protested greatly against the handing over of any rights to the Insurance Acts Committee. Sooner or later the new organization would find itself in the same difficulty and open to the same reproach as the Insurance Acts Committee.

Dr. BRACKENBURY said that the whole point at issue related to a rather remote possibility. There might be occasions on which the actual wording of the regulations would be left to the Insurance Acts Committee. The Commissioners would submit to the central negotiating body the regulations shortly before they were issued, and they would do this, not as a matter of right, but of courtesy, and the Committee could say whether they did actually embody the agreement previously arrived at.

The meeting agreed to the Herefordshire amendment that before proposals for alteration of regulations were accepted the Panel Committees should be consulted, but the CHAIRMAN, in putting the amendment, said that it was on the understanding which had been brought out in the discussion that occasions might arise in which the decision as to whether the regulations did verbally embody the proposals agreed upon must be left to the central negotiating body.

An amendment by Birmingham relating to the calling of a conference at short notice was withdrawn on the understanding that should such a course be necessary the representatives at the previous annual Conference would be invited.

The motion approving the scheme for collective bargaining and pledging the Panel Committees represented to carry it into effect, and instructing the Committee to take all possible steps to secure the loyal adherence of all Panel Committees, was then put to the meeting and carried. Ten representatives dissented, and requested that their names be taken, which was done.

PAYMENT OF INSURANCE PRACTITIONERS.

Dr. H. G. DAIN (Birmingham) had a motion on the agenda which he submitted in four parts. He said that last year the view was expressed that although they felt that increased remuneration was due to them, they should not press for it on account of the war. But the war had gone on, and all other grades of workers throughout the country were receiving increased payment and doctors also were getting increased remuneration from non-panel patients. Therefore he moved:

That because of the continuance of the war and the uncertainty of its duration, it has become impossible to postpone the reconsideration of the rate of remuneration of medical practitioners under the Insurance Act till the war is over.

This was put to the meeting and agreed to, and Dr. Dain then went on to say that the reason why they should press for increased remuneration was most admirably stated in the Interim Report when dealing with the future rate of

payment. He urged the Conference to express its opinion that an increase of the capitation fee should obtain as from the beginning of next year. The profession was now in a stronger position for getting increased remuneration than it would be at a later stage. From a political point of view this was quite the right time to carry the matter forward. He moved:

That the increased costs of living and of carrying on practice and other reasons require an increase in the capitation fee as from January 1st, 1918.

This was also agreed to, and Dr. Dain then moved his third proposition, which dealt with the nature of the advance to be made. A 3s. advance in the capitation fee meant a sum of approximately 1½ million for the profession, or an extra £3 a week to the income of a practitioner with a net panel of 1,000. He moved:

That the present capitation fee of 6s. 6d. plus 6d. for domiciliary treatment be raised to 10s., which shall cover the increased liabilities with regard to discharged sailors and soldiers and all the services now rendered to tuberculosis patients by panel practitioners.

Dr. A. FOSTER (Leicester) asked whether the increased capitation fee was intended to be permanent or was only for the duration of the war and some while afterwards.

Dr. BRACKENBURY said that he did not want the ten shillings to go forward as a definite and settled amount to be presented in the manner of an ultimatum. The case for a substantial increase in the capitation fee was overwhelming, but he would not like it to be understood that they should go to the Government with nothing more nor less than 10s. in their minds. Although he believed some such amount to be right, he did not want to be tied down to specific amounts or to specific dates.

Dr. B. A. RICHMOND (London) said that this opened up the question as to whether the Conference did give the Insurance Acts Committee the right to accept terms issued by the Government. They had been rather too ready to take the Commissioners' dictum that Panel Committees could have no data. The Commissioners replied to their contention that they were doing more work for less money by saying that the statistics they (the Commissioners) were obtaining confuted this argument, and that these went to show that the war had had quite another effect. He submitted that that ignored entirely the distinction between medical benefit and sickness benefit. Neither the Insurance Commissioners nor the Treasury could have data for the real amount of work which panel practitioners were called upon to do under present conditions, and accordingly he asked the Insurance Acts Committee to make an effort to get from individual practitioners and Panel Committees the data which did actually show not the amount of money which approved societies were paying out, but the number of visits and attendances which practitioners were making on a reduced list and a reduced income, but a much greater visiting list.

A REPRESENTATIVE said that if the increase of the capitation fee was in the nature of a war bonus, it had been the custom to make war bonuses in other cases retrospective.

Dr. H. J. CARDALE (London) pointed out that in the motion by Birmingham the argument in favour of an increased capitation fee was based on the increased cost of living and of carrying on practice, and if that was the case, details of work done had no significance.

Dr. J. HARRISON (Lancashire) asked how rural practitioners who did their own dispensing would be affected.

Dr. J. MILLER (Dorset) supported Dr. Brackenbury in urging that there should be no rigid demand for this increase to 10s.

Dr. H. F. OLDHAM (Lancashire) emphasized the importance of carrying out the suggestion of Birmingham that the domiciliary sixpence should be included in the capitation fee. Some of them might not know that the index register on which they were paid for medical attendance and the index register on which they were paid for domiciliary treatment were two totally different things. How the difference arose no one had been able to explain. Nominally the doctor should get 6d. for every insured person on his register.

Dr. J. R. DREVER (Glasgow) said that the difference between the two lists was due to the fact that some persons who were entitled to medical benefit were not entitled to sanatorium benefit.

Dr. DAIN maintained that the Conference must decide on a figure. With regard to the rural question, if panel practitioners obtained increased remuneration, it was their duty to see that the rural practitioners were more fairly dealt with.

Dr. W. J. YOUNG (Cambridgeshire) hoped that the drug question as well as that of mileage would be considered when discussing the case of the rural practitioner.

The third part of Dr. Dain's motion was agreed to, and he then moved:

That the Insurance Acts Committee be instructed to negotiate these terms with the Government.

Dr. C. J. PALMER (Nottinghamshire) moved an amendment declaring the present time to be inopportune to demand an increased capitation fee, and pressing for a war bonus instead, but this amendment he subsequently withdrew. His reason for raising the matter, he said, was a feeling among some of his fellow practitioners that it was advisable to refrain from any action which might jeopardize their panel practice. It had been suggested that the suspension of medical benefit was a possible step for the Government to take, and a certain amount of medical opinion was advocating that extremity.

Dr. F. COKE (Kent) moved an amendment instructing the Insurance Acts Committee to confer with the Association of Panel Committees and the Panel Medico-Political Union with regard to the collection of resignations should the Commissioners refuse the demand for an increased capitation fee.

Dr. E. H. M. STANCOMB (Southampton) asked why the present was an inopportune time to press for increased remuneration, when every other class in the community was doing so.

Dr. BRACKENBURY said that if the Birmingham proposition was carried the Insurance Acts Committee would have to prepare at once a full presentation of the case for an increased capitation fee. But he hoped the Conference would not listen to the amendment just proposed by Kent. The Conference had deprecated the formation of other associations and had resolved to place the interests of Panel Committees in the hands of the Insurance Acts Committee. It was therefore an unnecessary complication to ask it to deal with other bodies in regard to this matter. It did not follow that because one's objective was the same as that of another person one walked with him on the same road or used the same weapons.

The amendment by Dr. Coke was lost by a very large majority, whereupon

Dr. STANCOMB moved the addition of the following words to the end of the Birmingham motion:

And to organize the profession forthwith in furtherance of this object.

This was agreed to, and the Birmingham motion with this addition was then carried. The CHAIRMAN again put to the meeting the four sections of the motion, which had been carried piecemeal, and the motion in its entirety was adopted with one dissentient.

Major H. E. COUNSELL (Oxford) moved:

That this Conference strongly protests against the unfair payment for insurance work for the year 1916 as shown by the amounts paid in final settlement of the accounts for that year, and instructs the Insurance Acts Committee to inform the Commissioners that some system must be devised which will make the payments more in accordance with the signed agreements.

In his own area, where the amount due in final settlement for each insured person for 1916 was 1s. 11½d., the amount received was under 10d.

The motion was carried, and Dr. DAIN (Birmingham) moved further:

That in view of the constant discussion as to whether the basis on which the central pool is instituted is the best, the Commissioners be asked to allow a committee of six, appointed by the Insurance Acts Committee, to see all the figures and particulars of the process of calculation of the central pool, necessary to enable them to reassure the Local Medical and Panel Committees on the points that still remain in doubt; and to permit an actuary nominated by the President of the Institute of Actuaries to accompany the committee and confer with the Government actuary, afterwards making a report to the committee.

Dr. Dain said that the expense would be considerable, but his Committee was prepared to bear a share of the cost.

Dr. OLDHAM (Lancashire) said that there was no reason why they should not have a voluntary levy from all panel practitioners. In his county they had done away with the statutory penny; and a voluntary levy, to which 70 per cent. had subscribed, and which was 4d. a year for every name on the list, had proved very successful.

The CHAIRMAN said that as soon as the Insurance Acts Committee arrived at an estimate of the cost it would send round to Panel Committees and ask them what they would be prepared to contribute.

The motion was carried.

A motion by Dr. JAMES HOLMES (Bury), urging that each panel practitioner ought to be paid the full fee for all on his list, without deduction on the ground of inflation, was lost. A motion by Dr. G. J. B. CANDLER-HOPE (Yorkshire, N.R.) pressing for an increased mileage grant for rural practitioners was adopted; and Dr. BRACKENBURY promised that the Insurance Acts Committee should consider a suggestion by Dr. F. R. RADCLIFFE (Oldham) that the meetings of that Committee should be held in some more central position than London during the war. A further matter left for the consideration of the Committee was an amendment by Dr. H. F. OLDHAM (Lancashire), which was carried on being put to the vote, suggesting that a circular letter be forwarded to every panel practitioner impressing upon him his obligation to safeguard the interests of absentee practitioners on service by signing on all fresh acceptances on the panel who might so desire as for the absentee and not in his own name.

PRICE OF PETROL.

Dr. J. GOFF (Lanarkshire) had a motion insisting on the Government making special arrangements by which the medical profession should receive an adequate supply of petrol at Government rate.

The CHAIRMAN said that there was no such thing as a Government rate. The petrol was under the control of two American firms, and the Government were buyers in the petrol market just the same as any other competitor.

Dr. DAIN said that the present Government price was 2s. 3d. a gallon.

Dr. T. W. H. GARSTANG (Lincoln, etc.) said that the question of the rapidly increasing cost of petrol had given rise to a very large number of complaints received at the offices of the Association, and had been considered by the Medico-Political Committee, who held that the proper remedy was for the practitioner to put up his fees.

Dr. GOFF withdrew his motion on the understanding that the Insurance Acts Committee would take the whole subject into consideration.

THE CHAIRMAN OF THE CONFERENCE.

The CHAIRMAN (Dr. J. A. Macdonald), who had to leave the meeting at this stage, referred to a later motion by Lanarkshire that the Chairman of the Conferences should be elected by the representatives and not chosen for them. He suggested that the best way would be to allow the Insurance Acts Committee to elect a chairman and give him a long time to study the agenda. There were evident dangers, in view of the complexity of the business, if a chairman were elected on the morning of the meeting.

The Conference passed a vote of thanks by acclamation to Dr. Macdonald as he left the room, and Dr. T. W. H. Garstang occupied the chair for the remainder of the proceedings. Dr. GOFF withdrew the Lanarkshire amendment with regard to the appointment of chairman.

On the motion of Dr. H. C. MACTIER (Burton-on-Trent) the subject matter of various motions was referred to the Insurance Acts Committee. These related to certificates, notices of removal and suspension, and the right of appeal by medical practitioners against the decision of the Insurance Commissioners.

Dr. A. FOSTER (Leicester) moved that a Conference of Representatives of Local Medical and Panel Committees be convened twice a year, and at other times upon a requisition of not less than one-fourth of the total number of committees.

Dr. BRACKENBURY pointed out that each conference cost the British Medical Association between £150 and £200, apart from the cost to the committees occasioned by the attendance of their representatives.

Dr. WILLIAMS-FREEMAN (Hampshire) supported the motion, and thought that there would be plenty of matters to interest two conferences a year, though he agreed that

it was hardly fair to ask the British Medical Association to bear the cost.

The CHAIRMAN suggested that the resolution in a mandatory form could hardly be satisfactory to the meeting, and on his suggestion the mover agreed to refer the matter to the Insurance Acts Committee.

It was also agreed, on the motion of Dr. CUMING ASKIN (Suffolk, E.), to refer to the Committee the advisability of altering the method of electing the fifteen direct representatives.

VOLUNTARY HOSPITALS AND THE TREATMENT OF DISCHARGED DISABLED MEN.

Dr. F. R. RADCLIFFE (Oldham) moved a resolution, for which he had been unable to find opportunity earlier, on the subject of voluntary hospitals and the treatment of discharged disabled soldiers:

That entirely apart from and above the amount paid to the governors of voluntary institutions from the State or local authorities for maintenance and attendance on discharged men, an amount should be paid for professional services rendered by the medical staff according to the scale to be agreed upon by the British Medical Association and the Ministry of Pensions.

Dr. BRACKENBURY said that this matter was scarcely within the province of the Conference, but the Association was fully alive to its importance, and had taken serious action with regard to it. The Ministry of Pensions had replied that they were not prepared under existing circumstances to suggest that there should be any such payment to the hospital staff. The Association had urged the staffs to refuse to undertake attendance unless the terms permitted a payment being made to them for the work they did. This attitude had met with a very favourable response all over the country.

The motion proposed by Dr. Radcliffe was carried.

RESULT OF ELECTION FOR COMMITTEE.

The selection of fifteen members for appointment on the Insurance Acts Committee was announced as follows:

Group A.—Scotland: Dr. J. R. Drever (Glasgow), Dr. J. Goff (Bothwell).

Group B.—Northumberland, Durham, Cumberland, Westmorland, Yorkshire, North Riding: Dr. H. L. Rutter (Newcastle-on-Tyne).

Group C.—Yorkshire, East and West Ridings: Dr. P. V. Fry (Sowerby Bridge).

Group D.—Lancashire and Cheshire: Dr. T. Campbell (Wigan), Dr. H. F. Oldham (Morecambe).

Group E.—Wales and Monmouthshire, Herefordshire and Shropshire: Dr. Hugh Jones (Dolgelly).

Group F.—Cornwall, Devonshire, Somersetshire, Dorsetshire, Isle of Scilly, and Gloucestershire: No nomination.

Group G.—Hampshire, Wiltshire, Berkshire, Oxfordshire, Buckinghamshire, Isle of Wight: Dr. J. P. Williams-Freeman (Andover).

Group H.—Kent, Surrey, and Sussex: Dr. G. G. Genge (Croydon).

Group I.—Middlesex, Herts, and Essex: Dr. H. B. Brackenbury (Stroud Green).

Group J.—Bedfordshire, Northamptonshire, Suffolk, Norfolk, Lincolnshire, Cambridgeshire, Huntingdonshire, Rutland, Isle of Ely, and Soke of Peterborough: Dr. C. Frier (Grantham).

Group K.—Derbyshire, Leicestershire, Nottinghamshire, Staffordshire, Warwickshire, and Worcestershire: Dr. T. Ridley Bailey (Bilston, Staffs), Dr. H. G. Dair (Birmingham).

Group L.—London County: Dr. H. G. Cowie (Denmark Hill).

The counties given in the above list include the county boroughs.)

The Conference passed the necessary formal resolutions with regard to the minutes, and the reference of them to the Insurance Acts Committee for appropriate action; and separated at 9.40 p.m., after passing hearty votes of thanks to Dr. Brackenbury for the manner in which he had conducted the business of the Insurance Acts Committee at the Conference, and to Dr. Garstang, for presiding over the later stages of the session.

A LIST of periodical publications, official reports, and Blue Books in the Library of the British Medical Association available for issue to members on loan has been printed, and copies can be obtained free on application to the Librarian at the house of the Association, 429, Strand, W.C.2. The regulations governing the loan of these publications are stated in the introduction to the list. The Library is open for consultation from 10 a.m. till 5 p.m. (on Saturdays till 2 p.m.).

Meetings of Branches and Divisions.

DORSET AND WEST HANTS BRANCH.

THE autumn meeting of the Branch was held at Bournemouth on October 17th, when the President, Dr. T. HOWARD, was in the chair.

Vote of Condolence.—On the motion of Dr. JOHNSON SMYTH a very sincere vote of condolence with the members of the family of the late Dr. Roberts Thomson (formerly President and Chairman of Council of the Association) was passed by the members standing, and deep sympathy was also expressed with Dr. Mahomed of Bournemouth, and Dr. Wright of Wool, in the loss of their sons at the front.

Annual Meeting.—It was decided to hold the annual meeting at Bournemouth in May, 1918.

Election of Officers for 1918-19.—The following were elected:

President: Dr. Harold Simmons. *Vice-Presidents:* Dr. Williams (Bournemouth), and Dr. Luther (Puddletown).
Honorary Secretaries: Dr. F. Fowler and Mr. P. A. Ross.

Scientific Proceedings.—Dr. F. C. FORSTER read a paper on the management of neurasthenia, psychasthenia, shell-shock, and allied conditions, which was followed by a discussion in which Dr. MACDONALD, Dr. J. SMYTH, Dr. FOWLER, Dr. SIMMONS, Dr. E. BOND, Dr. H. DAVY, and Dr. LE FLEMING took part, and Dr. FORSTER replied. Dr. HUMPHREY DAVY read a paper on certification of patients for asylum treatment, which was briefly discussed by Dr. MACDONALD, and Dr. H. DAVY replied.

Luncheon.—Members were entertained by the Bournemouth practitioners to luncheon and tea at the Hotel Metropole.

SOUTH-EASTERN OF IRELAND BRANCH.

AN ordinary meeting of the South-Eastern of Ireland Branch was held in Kilkenny on October 3rd, when Dr. M. MITCHELL was in the chair.

Dr. LAFFAN gave notice that he would move a further resolution:

Protesting against the deprivation of about 800 provincial medical men by an act of the Local Government Board of the statutory provisions conferred on them of the eligibility for the important positions of county councillors and to call attention to the scant help given to our resolution of May last by various public bodies and to move a resolution thereon.

The following resolution proposed by Dr. DENIS WALSH, seconded by Dr. M. MITCHELL, was unanimously adopted:

That the advice of the solicitor of the British Medical Association be asked as to whether a dispensary doctor or a medical officer of a workhouse in Ireland can be disqualified from being a member of a county council by any regulation of the Local Government Board in Ireland or whether he is disqualified by any statute.

Dr. P. Murphy (Carrick-on-Suir) and Dr. John Quirke (Cashel) were elected unanimously members of the Association. The applications of two other candidates were rejected.

THE FUTURE OF THE INDIAN MEDICAL SERVICE.

THE following letter has been forwarded to the Secretary of State for India by the Naval and Military Committee of the British Medical Association:

October 8th, 1917.

The British Medical Association has considered the report of the Royal Commission on the Public Services in India.

The Association notes with profound concern and disappointment the whole trend of the above report and its recommendations so far as they relate to the Indian Medical Service. The various points in the Association's Memorandum on the present position and future prospects of the Indian Medical Service, which was submitted to the Royal Commission, have received most scanty attention. In its evidence given before the Royal Commission, the Association drew attention to numerous grievances which, if allowed to continue, could not fail to result in a marked deterioration in a service which has already become unpopular with medical men of British parentage (as is instanced by the fact that the late Secretary of State for India, in October, 1913, requested the assistance of the Association in ascertaining the probable cause of the

deficiency of high class candidates for the Indian Medical Service), but there is little or no evidence in the recommendations of the Royal Commission of any intention to redress these grievances. The Association feels that the real storm centre is the question of limiting private practice of Indian Medical Service officers, and it desires that there should be no ambiguity in the future as to the policy to be adopted by the Secretary of State for India on this subject.

Another point to which the Association attaches great importance is the position of the Surgeons-General. In the opinion of the Association—and this point was strongly emphasized to the Royal Commission—the Surgeon-General should be a Secretary to Government, and the personal assistant to a Surgeon-General an Under Secretary to Government in the Medical and Sanitary Departments, both being paid as such. It will not be sufficient to give the Surgeons-General and the Inspectors-General of civil hospitals "regular and direct access" to the head of their Province or to the member of Council in charge of the Medical Department where there is a Council form of government. The present system whereby the recommendations of the Surgeons-General on medical questions can be criticized or set aside by non-medical men is a constant source of irritation which can only be removed by making the Surgeons-General secretaries to Government, and giving them complete control over their medical subordinates in all matters, including transfers from one station to another within the district.

The Association is anxious to know to what extent the Government proposes to give effect to the recommendations of the Royal Commission, and it will then be in a position to place the future prospects of the officers of this service clearly before the profession, and to give such advice on the subject to possible applicants as they are entitled to expect from it. The Association does not attempt to dictate the terms which the Government of India should offer to its medical officers, but knowing as it does the feeling of the medical profession it desires to make it clear to the Secretary of State for India that failure to redress the grievances which the Association has pointed out will most certainly result in a very marked augmentation of the deterioration already in progress in the class of recruits to the Indian Medical Service.

Before any definite decision is taken by the Government of India on the questions raised in the report of the Royal Commission, the Association is anxious that you should have its views before you, and I am directed to request that you will be so kind as to receive a deputation from the Association, who will place before you in greater detail the opinions which the Association has formed as a result of careful inquiry.

INSURANCE.

LOCAL MEDICAL AND PANEL COMMITTEES.

COUNTY OF BEDFORD.

At a meeting of the Panel Committee on July 10th it was reported that the term of office of the committee had been extended to July 15th, 1918. It was resolved to request the clerk to the Insurance Committee, when issuing medical cards to insured persons, to enclose a slip printed in red ink, asking that the card be presented to a panel doctor at once for signature under part A.

DERBYSHIRE.

At a meeting of the Local Medical and Panel Committee on September 25th the representatives of the committee to the Conference of Local Medical and Panel Committees were instructed to support the resolution set out in the circular issued by the British Medical Association expressing renewed confidence in the Insurance Acts Committee as the central negotiating body of the Local Medical and Panel Committees of the country.

STAFFORDSHIRE.

At a meeting of the Local Medical and Panel Committee on July 3rd it was proposed that a separate fund should be established with regard to new acceptances on the panel, and that all practitioners on the panel, including doctors absent on service, should be credited with a percentage of payments proportionate to the number of persons on their lists at the beginning of the war. It was reported that the period of office of the members of the committee had been extended until July 15th, 1918. Communications from the Panel Medico-Political Union with

regard to the Advisory Committee and from the York Panel Committee with regard to the working of the Insurance Acts were received.

RENFREW COUNTY.

At the last meeting of the Renfrew Panel Committee suggestions for a division of the area into districts for the purpose of a medical referee scheme were approved for submission to the Insurance Committee, and it was agreed that the first referees to be appointed should hold office until December 31st, 1918. In a case where an insured person asked for assignment and the practitioner geographically nearest to the insured person's house by a rough moorland road was much further away than another doctor when the distance was judged by ordinary road mileage, the Committee expressed the opinion that "nearest practitioner" meant the practitioner whose residence to the insured person was nearest taking the ordinary road mileage as the basis of measurement.

INSURANCE ACT IN PARLIAMENT.

PANEL DOCTORS' REMUNERATION.

MR. SNOWDEN asked Sir E. Cornwall if he was aware that the panel doctors in many parts of this country, especially the rural districts, had received only from 25 to 50 per cent. of the sum due to them for their services for the year 1917? Sir E. Cornwall replied that in the great majority of cases the final payments for the year 1916 had been made. In those areas where some balance was outstanding the amount would only be small as the sums which had been advanced monthly or quarterly during the year would have approximated closely to the total sums which would be found to be due on the final settlement. If particulars of any cases were supplied, inquiries would at once be made.

AIR RAIDS AND SICK BENEFIT.

Mr. Chancellor asked whether approved societies were entitled to refuse sick benefit to insured persons on the ground that their illness had been caused by air raids. Sir Edward Cornwall (for the National Health Insurance Commissioners) replied that the question raised a point of law, but he was advised that approved societies would not be entitled to refuse sickness benefit to insured persons on the ground that their illness had been due to air raids unless the case was one in which the court would hold that the injury received in the air raid had arisen out of, and in the course of, the member's employment. In that case the matter must be one for compensation under the Workmen's Compensation Act, and in accordance with Section 11 of the National Insurance Act, 1911, benefit would not be properly payable.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are announced by the Admiralty:—Fleet Surgeon E. L. Grazebrook to the *Queen*; R. J. Mackeown, M.B., to the *Emperor of India*; Staff Surgeon A. B. CURRENT NOTES.

Membership of the Association.

THE report of the Organization Committee, which was presented to the Council at its quarterly meeting on October 24th, contained a return showing the position of the membership of the Association between June 1st and September 26th, 1917. New members joining the Association during the period numbered 1,097, and there was a net increase of 963. The total membership at the end of September was 21,259, as compared with 20,905 at the corresponding date in 1916. These figures will, no doubt, give satisfaction to those who have worked on behalf of the Association throughout the past twelve months in face of all the difficulties due to the war. The large number of applications for membership from medical officers serving with the Forces indicates that the work of the Association and its JOURNAL are appreciated by those on active service.

The Education Bill.

The Education Bill recently introduced into Parliament contains certain clauses which have a direct bearing upon general practice. At the instance of the Medico-Political Committee a circular was accordingly issued on October 16th to honorary secretaries of Divisions and Branches of the Association, desiring that the attention of the profession should be drawn to the proposals contained in clauses 18 and 19 of the bill, and enclosing a memorandum analysing these provisions from the medical point of view. Since a copy of this memorandum has been sent to every member of the Association, it is only necessary to say here that the clauses in question, if enacted, would extend the duties of local education authorities to include the provision of medical inspection and medical treatment for all children and young persons between the ages of 2 and 18. It is maintained by the Association that such changes ought to be confined to medical inspection only, and that the position as regards treatment should be left unaffected pending further legislation dealing with the whole subject of public health. If the medical treatment authorized by clauses 18 and 19 were carried out on the plan hitherto usually adopted by local education authorities—namely, by the appointment of salaried officers—this would seriously affect the work and status of general medical practitioners. The Association has already taken steps to have these clauses amended in Parliament, but such central action should be reinforced by local endeavours. Since the issue of the circular and memorandum mentioned above, the Chancellor of the Exchequer has stated in the House of Commons that it will not be possible to pass the Education Bill this session. There is, however, good authority for believing that the bill will be proceeded with next January. This should give time for full discussion of the matter in the Divisions and throughout the profession generally.

Medical Certificates for Mmunition Workers.

At the last meeting of the Representative Body the subject of medical certificates required by the Ministry of Munitions was briefly debated. One member told the meeting that in his district practitioners for the most part used their own ordinary certificate forms. The matter has since been considered by the Medico-Political Committee, and a recommendation from it was approved by the Council at its last meeting. Practitioners are advised to decline to sign the elaborate form of certificate of incapacity for work issued by the Ministry unless an adequate fee is paid for it, and it is pointed out that the Representative Body has decided that one shilling is not adequate for that form of certificate. The recommendation is eminently reasonable and should be noted by medical men and women practising in munition areas.

Meetings of Branches and Divisions.

EDINBURGH BRANCH: EDINBURGH AND LEITH DIVISION.

A MEETING of this Division was held on October 19th, when Dr. WILLIAM STEWART, Chairman, presided.

Votes of Congratulations.—It was intimated that the executive had sent congratulations to Lieut.-Colonel J. M. Cotterill, C.M.G., and Mrs. Chalmers Watson, M.D., C.B.E., on their respective honours.

Annual Representative Meeting.—Drs. LUNDIE and STEVENS, having reported on the proceedings of the last Representative Meeting and on the motions forwarded by the Division, were cordially thanked for their services.

Ministry of Health.—On the motion of Dr. STEVENS, seconded by Dr. MCKENZIE JOHNSTON, it was resolved:

That, in accordance with the resolution *re* Ministry of Health passed unanimously on June 21st, this meeting welcomes the statement of the Prime Minister, that the introduction of a bill for this purpose is postponed.

Medical Attendance on Discharged Disabled Soldiers and Sailors.—The following motion by Dr. STEVENS, seconded by Dr. LUNDIE, was lost; a motion to proceed to the next business having been carried:

That this meeting adheres to the two resolutions on the subject of provision for medical attendance on discharged disabled soldiers and sailors, unanimously passed by the Division on June 21st, and disapproves of the provisions made, in so far as they are not in accordance with these resolutions.

Unqualified Dental Practice.—The executive reported its action with regard to a letter from the Central Office requesting inquiry into unqualified dental practice. The executive had the assistance of Major Guy, L.D.S.E.

Prescription of Cocaine and Opium.—The regulations with regard to prescriptions containing cocaine salts and opium for all classes of patients were read, as were also the regulations for prescriptions containing hypnotic and sedative drugs for any member of H.M. forces. The executive recommended that a request be sent to the Central Council to approach the Privy Council to have the regulations of the latter group extended to the civilian population.

Veneral Diseases Scheme in Edinburgh.—The SENIOR SECRETARY explained the draft scheme, and gave the information obtained by a deputation invited by the Public Health Committee to a conference with other interested medical bodies. The executive brought forward the following motion:

That medical officers (both chief and assistants) should be permitted to receive fees for consultations from patients able and willing to give them, also emoluments from any lectureship, so that medical officers of high scientific attainments may be obtained for the posts.

Dr. LUNDIE proposed and Dr. W. MILLAR seconded the following amendment:

That this meeting disapproves the proposal made in the report of the M.O.H. on the scheme prepared with regard to venereal diseases in Edinburgh, to appoint a whole-time (senior) clinical assistant medical officer, a course which they understand has not been carried out in any area in England or Wales.

The amendment was lost, and the motion of the executive was then passed as a substantive motion. The Secretary was instructed to send the motion to the town clerk, M.O.H., and the convener of the Public Health Committee.

Maternity and Child Welfare Scheme in Edinburgh.—The following two resolutions were adopted unanimously:

That the nurses under this scheme should advise a mother to obtain the services of a doctor for her child or for herself for maternity troubles when the nurses judge it desirable, but shall not recommend any treatment on their own responsibility.

That any one visiting under this scheme who thinks it is her duty to advise that medical treatment is necessary ought, in the first place, to ascertain whether the patient has a private medical attendant, and if she has a doctor, or is willing to obtain one, ought to advise that his services be obtained, and ought only to recommend treatment at or through an institution if there is not a private medical attendant available.

The report of the special committee on the participation of practitioners in the scheme was read to the meeting.

GRENADA BRANCH.

Veneral Diseases Ordinance.—The Venereal Diseases Ordinance before the legislature was considered at two meetings of the Branch on July 19th and August 22nd, when various amendments were submitted, some of which were adopted by the Branch. The ordinance, which was passed on August 30th, will impose a great deal of work on medical officers. Provision has been made for the free treatment of cases unable to pay, but no decision has been reached as to the remuneration the medical officers are to receive.

Dr. Paterson, who has been appointed colonial surgeon in succession to Dr. Hatton, has become president of the Branch.

Association Notices.

ELECTION OF COUNCIL, 1917-18.

NOTICE is hereby given that nominations for a candidate for the election as a Member of Council by the Glasgow and West of Scotland (five county Divisions), Border Counties, and Stirling Branches for the year 1917-18 must be forwarded to reach the Financial Secretary and Business Manager, at the office of the Association, not later than Saturday, November 17th. Each nomination must be on the prescribed form, copies of which will be furnished by the Financial Secretary and Business Manager upon application.

Separate forms have been prepared:

- (A) For a nomination by a Division, and
- (B) For a nomination by any three Members of a Branch respectively.

Those applying are requested to state for which purpose the form is desired.

An announcement of the Nominations received will be made in the JOURNAL of November 24th, 1917.

Election will be by voting papers. These papers will contain the names of all duly nominated candidates, and will be issued from the Central Office on Monday, November 26th, and will be returnable not later than Saturday, December 1st.

The result of the election will be published in the JOURNAL on or before December 8th, 1917.

By Order of the Council.

GUY ELLISTON,

Financial Secretary and Business Manager.

November 3rd, 1917.

IRELAND.

IRISH MEDICAL COMMITTEE.

A MEETING of the Irish Medical Committee was held in the Royal College of Surgeons, Dublin, on October 19th. Dr. R. M. BLAKE was in the chair, and the following members were present: Drs. J. S. Darling, J. R. Davison, F. C. Fitzgerald, S. Gawn, J. Giusani, D. Gray, W. J. Healy, J. McElroy, T. J. McGrath, W. W. Murphy, B. C. Powell, D. Walshe, Dr. T. Hennessy (Medical Secretary), and Mr. C. H. Gick (Secretary). The outgoing officers of the Irish Medical Committee and outgoing members of the Subcommittees were re-elected.

The Position of Irish Medical Services in the Event of any Changes in Irish Government.

A committee to watch and represent the interests of the Irish medical profession was appointed, and the Secretaries, in consultation with the chairman of the Irish Medical Committee (Mr. R. J. Johnstone, F.R.C.S.) were directed to communicate with the Secretary of the Irish Convention to inform him of the attitude of the Irish medical profession regarding the establishment of a National Medical Service. In 1911 over 90 per cent. of the profession in Ireland declared in favour of the reform of the Poor Law and other medical services in Ireland, on the following lines:

1. A National Medical Service entered by examination; payment by the State of adequate salaries, progressive according to service, and compulsory superannuation on retirement.
2. The establishment of a properly organized Public Health Service.
3. A system of hospitals accessible to all requiring treatment free from workhouse or pauper taint. The question of medical attendance on private patients in these hospitals was to receive special consideration.

Committee: Mr. R. A. Johnstone, Chairman; Dr. J. Power, Vice-Chairman; and Dr. R. M. Blake, Right Hon. M. F. Cox, M.D., Drs. James Craig, J. S. Darling, J. Giusani, J. H. Jellett, Mr. J. S. McArdle, F.R.C.S.I., Drs. W. W. Murphy, J. F. O'Carroll, M.D., P.R.C.P.I., R. J. Rowlette, Mr. W. Taylor, P.R.C.S.I., Dr. D. Walshe, Dr. T. Hennessy, Medical Secretary, and Mr. C. H. Gick, Secretary.

Number of Insured Persons in Insurance Areas and Dispensary Districts.

A communication from the Insurance Commission, Ireland (August 31st, 1917), was considered, explaining the causes of the difference in the numbers of insured persons as made out by the Insurance Commission and those made from the index registers of the Insurance Committees. The Commissioners stated that the returns made from the index registers of the Insurance Committees are inflated owing to the following causes: (1) They contain the names of the same person in duplicate or even in triplicate; they still include the names of persons (2) who have died; (3) who have joined H.M. forces; (4) who have gone out of insurance; (5) who have emigrated to Great Britain; (6) who have transferred their residence to the area of other committees, which latter have subsequently obtained duplicate notifications from the societies of which the insured persons were members. Arising out of the Commissioners' letter, it was proposed by Dr. GRAY, seconded by Dr. DAVISON, and passed unanimously:

That, in view of the great dissatisfaction regarding the returns of the numbers of insured persons, the Irish Medical Committee suggest that the Insurance Commissioners should ask all approved societies to make a return of their insured members in each insurance area, in order that definite figures may be obtained yearly for the purpose of payments.

Treatment of Tuberculosis.

A circular letter from the Local Government Board addressed to county and county borough councils and to clerks of unions, dealing with the treatment of tuberculosis and the action of certain councils in ordering their tuberculosis medical officers to undertake the domiciliary treatment of tuberculous patients, to the exclusion of the usual medical attendant, were considered, and in connection therewith the following resolution was unanimously passed:

That the Irish Medical Committee desires to remind the Local Government Board of the absolute necessity of co-operation between the patient's doctor and the tuberculosis officer for the purposes of medical treatment, and would look with grave distrust upon any scheme which would transfer patients from the care of their usual medical attendant to that of the tuberculosis officer.

POOR LAW MEDICAL COMMITTEE.

A meeting of the Irish Poor Law Medical Committee held on the same day, previous to the meeting of the Irish Medical Committee, was attended by the following members: Dr. R. M. Blake (in the chair), Drs. J. S. Darling, F. C. Fitzgerald, S. Gawn, J. Giusani, W. J. Healy, W. W. Murphy, B. C. Powell, D. Walshe, Dr. T. Hennessy (Medical Secretary), and Mr. C. H. Gick (Secretary).

A letter was read from Dr. Power (Ardinnan), urging that the necessary steps should be taken by the Irish Medical Committee to bring to the notice of the Irish Convention the very unsatisfactory position of the Irish Medical Services, with a view to radical reforms. The Poor Law Subcommittee forwarded a recommendation to the Irish Medical Committee to appoint a committee that would represent and promote the interests of the Irish medical profession in the event of any changes in Irish government. The Irish Medical Committee at its meeting adopted the recommendation of the Poor Law Medical Committee.

INSURANCE.

LOCAL MEDICAL AND PANEL COMMITTEES.

London.—At the meeting of the London Panel Committee on October 23rd it was agreed to call the attention of the Commissioners to the following administrative matters: (1) To ask the Commissioners to supply such information as would enable the Committee to learn whether the degree of inflation was on the increase, and to explain the steps which were being taken to effect a central clearance of the registers of Insurance Committees throughout the country; (2) to draw the attention of the Commissioners to the question of late notification to doctors of the names of insured persons who ceased to be entitled to medical benefit, and to ask what steps were being taken to deal with the difficulties arising out of this circumstance; (3) the Commissioners were asked, in the case of approved societies demanding weekly certificates in cases of prolonged incapacity upon intimation being given by a practitioner, to take steps to satisfy themselves as to the likelihood of prolonged incapacity of insured persons with a view to the giving of certificates at less frequent intervals.

Surrey.—At a meeting of the Panel Committee on July 13th a report was received from the subcommittee upon the inflation of the lists of doctors who dispense, with special reference to rural areas, advising that whilst the contention that rural practitioners had a distinct grievance seemed to be substantiated the subject should be postponed for further consideration until after the war. It was agreed to notify the clerk of the Surrey Insurance Committee that there was therefore now no further objection to the final division of the unallotted fund for 1916.

Bedfordshire.—At a meeting of the Local Medical and Panel Committee on September 25th it was agreed that the new scheme for the medical benefit of invalided sea men, marines, and soldiers was workable, and that the remuneration should be accepted as adequate unless and until experience proved otherwise. The secretary was instructed when issuing the minutes to add a footnote requesting doctors to be careful when signing prescriptions for other medical men to sign for those for whom they are acting and not in their own name.

Oxford.—At a meeting of the Local Medical and Panel Committee on September 29th the Secretary reported on the payments to practitioners on the panel for 1916, and showed that, calculated on the doctors' acceptances, the amount credited showed a deficiency of £657 5s. 6d., representing 1,546 persons on those lists for whom no payment was being made. There was also no credit for the unallotted, numbering 2,300. The position was regarded as so unsatisfactory that the representative of the Committee was instructed to bring the matter before the conference on October 18th.

The arrangement for the treatment of disabled soldiers on the attendance basis was approved, and it was decided to support the motion of confidence in the Insurance Acts Committee and not to join any other proposed association of Local Medical and Panel Committees.

Renfrewshire.—At a meeting of the Panel Committee on September 26th it was decided to point out to practitioners the necessity of keeping a careful note of all services rendered to discharged disabled soldiers under the new procedure, and of duly rendering complete accounts to the Committee.

INSURANCE NOTES.

WE have received from the National Health Insurance Commission (England) a copy of a letter addressed by the Commissioners to the Lancashire Insurance Committee with reference to the report of the Inquiry Committee which inquired into the case of Dr. William Hamilton of 95, Wallgate, Wigan. The Commissioners observe from the report that, owing to the inability of the Insurance Committee to produce the necessary evidence, the inquiry proved abortive, and accordingly they do not propose to take any further action in the matter. The Commissioners add that they concur in the view expressed by the Inquiry Committee that it is matter for regret that in the circumstances the inquiry was allowed to proceed to a hearing.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments have been made at the Admiralty: Fleet Surgeons E. J. Finch, C.M.G., to the *Pembroke*, additional for disposal; T. W. Philip, M.B., to the *Fivild*; E. CURRENT NOTES.

National Insurance Central Pool.

THE recent Conference of Local Medical and Panel Committees made the suggestion that a Subcommittee of six, appointed by the Insurance Acts Committee, together with an actuary nominated by the President of the Institute of Actuaries, should be allowed to see all the figures and particulars of the process of calculation of the Central Pool necessary to enable them to reassure the Local Medical and Panel Committees on the points that still remain in doubt. The Commissioners have assented, on the understanding that such figures as those relating to the actual monthly enlistments and discharges supplied to the Commissioners by the War Office and Admiralty can only be shown during the investigation to the Actuary accompanying the Subcommittee. The Insurance Acts Committee has accepted this condition, and has invited the President of the Institute of Actuaries either to act himself or to nominate an actuary of high professional standing, who would be willing to undertake the proposed investigation in conjunction with the Subcommittee. The Subcommittee appointed by the Insurance Acts Committee consists of Dr. H. B. Brackenbury (London), Dr. H. G. Dain (Birmingham), Dr. H. L. Rutter (Newcastle), Dr. P. V. Fry (Sowerby Bridge), and Dr. R. Paterson (Liverpool) and Dr. J. C. Lyth (York), subject to the consent of the last two to act.

Lay Radiographers.

While there is a mechanical side to radiography, in which the lay assistant can be extremely useful to the medical radiographer, it is highly undesirable that lay persons, however skilled in technique, should be encouraged to set up in practice by themselves and pose as experts in the interpretation of skiagrams. At the present time the army employs a very large number of x-ray assistants in base hospitals and clearing stations; and many of these men, under the tuition of medical officers, have attained much skill in the taking and development of radiograms. A good many also have acquired more self-confidence in diagnosis than is good for them or for the public. It is probable, therefore, that after the war numbers of these men will seek employment as expert radiographers in civilian life, and we learn that already a certain number of discharged soldiers have applied to medical men for practical tuition in x-ray work with this object in view. The Medico-Political Committee of the Association, in view of these circumstances, has recommended that some line of policy should be adopted in order to meet the position which seems likely to arise after the war. The Committee recommended that the practice of medical radiography by lay persons, except under the direct instruction and supervision of medical practitioners, ought not to be encouraged, and the Council concurred in this view at its last quarterly meeting.

Medical Certificates for Munition Workers.

In a note published in the SUPPLEMENT of November 3rd attention was drawn to the elaborate form of certificate of incapacity for work issued by the Ministry of Munitions, and it was pointed out that the Council at its last meeting advised medical practitioners to decline to

sign this form unless an adequate fee is paid for it. We are now informed that a precisely similar form is being issued by the Inspection Department of the Royal Arsenal, Woolwich, and that the Department is requesting practitioners to be good enough to sign the prescribed certificate, but is not offering any payment. We believe that employers of labour in other parts of the country are also adopting the form of certificate originally issued by the Ministry of Munitions, and it will be well for practitioners to be on their guard, and to decline to sign any such elaborate form unless an adequate fee is paid.

IRISH COMMITTEE.

A MEETING of the Irish Committee was held on October 19th at the Irish Offices, 16, South Frederick Street, Dublin, when Dr. J. GUSANI presided.

Election of Officers.

All the outgoing officers were re-elected, and Drs. W. W. Murphy, J. Power, and H. T. Warnock were co-opted members of the Committee.

Poor Law Medical Officers as County Councillors.

A resolution was considered from the South-Eastern (Ireland) Branch protesting against the Order of the Local Government Board (Ireland) preventing Poor Law medical officers acting as county councillors, and advising that the Solicitor of the Association be consulted as to its legality. It was unanimously resolved:

That the Irish Committee approve of the resolution of the South-Eastern (Ireland) Branch in connexion with the General Order of the Local Government Board debarring Poor Law medical officers from sitting on county councils, and request the Council to take such action in the matter as it may be advised.

Poor Law Medical Officers' Salaries.

Solicitor's advice was considered regarding the powers of the Local Government Board to fix the salaries of Poor Law medical officers. The matter was fully discussed, and the following resolution unanimously passed:

That owing to the actual and threatened resignations of Poor Law medical officers in different parts of Ireland, as the result of the refusal on several occasions of their boards of guardians to give them adequate salaries, the Irish Committee calls upon the Local Government Board, in the interests of the sick poor and their medical officers, to fix the salaries of Poor Law medical officers so that they may be in a position to discharge efficiently their duties under the Medical Charities Acts.

Treatment of Disabled and Discharged Soldiers.

It was unanimously resolved:

That the Irish Committee of the British Medical Association call upon the Ministry of National Service to take immediate steps to arrange for the treatment of disabled and discharged soldiers in Ireland, as, at the present time, they are for the most part treated in charitable institutions and under the Poor Law Medical Charities Acts.

Maternity and Child Welfare.

It was unanimously resolved:

That the Irish Committee, whilst approving of the very excellent scheme for maternity and child welfare formulated by the Local Government Board through its medical commissioner, Dr. Bigger, is convinced that it will be for the most part a failure owing to (1) the insufficiency of the Treasury grant, which is only £5,000 for all Ireland; (2) the adoption of the scheme being voluntary by the local sanitary authorities, who will be found, in many instances, unwilling to levy rates towards defraying their part of the expenses of the scheme.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are announced by the Admiralty: Staff Surgeons J. Fullerton, M.B., to the *Glory*; R. Connell to the *Victory*, additional, for Haslar Hospital; H. M. Langdale to the *Calliope*. Temporary Surgeons: T. H. W. Idris, to the *Victory*; W. F. Bowen and W. P. Vicary, to the *Vivid*; F. A. Fiddian and W. Whitfield, to the *Glory*; G. W. Carte, M.B., to the *Vivid*, additional, for Plymouth Hospital; H. F. Percival to the *Africa*; A. G. Swain, M.B., to the *Tiger*; F. R. Law to the *Superb*; W. S. O'Loughlin to the *Wildfire*; E. P. L. Hughes to the *Crescent*. To be temporary Surgeons: J. W. McK. Nicholl, R. W. Payne, H. G. Taylor, F. G. Pailthorpe, A. P. Kennedy, B. L. Skeggs.

ARMY MEDICAL SERVICE.

Colonel M. J. Sexton, C.B., M.D., is retained on the active list under the provisions of Articles 120 and 522 Royal Warrant for Pay and Promotion, and to be supernumerary.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel J. C. Connor, C.M.G., M.B., relinquishes the rank of temporary Colonel on reposting.

The undermentioned relinquish the acting rank of Lieut.-Colonel on reposting: Major C. H. Straton, Captain H. Gibson.

The undermentioned Majors retain the acting rank of Lieut.-Colonel whilst in command of a casualty clearing station: T. F. Ritchie, D.S.O., M.B., E. W. Siberry.

Temporary Major G. Stoker relinquishes his commission on account of ill health, and is granted the honorary rank of Major.

Captain J. B. A. Wigmore, M.B., to be acting Lieut.-Colonel whilst in command of a field ambulance.

Temporary Captain G. K. Allan, M.B., relinquishes his commission on account of ill health contracted on active service.

Temporary Captain C. J. Sparrow relinquishes his commission and is granted the honorary rank of Captain.

Temporary Captains relinquish their commissions: D. S. Cooper, M.B., W. S. Allan, M.B., J. Lindsay, M.D., M. Polson, M.B., I. B. D'Olier, M.D., H. V. Drew, F.R.C.S., A. G. Bodman, J. I. Johnson, A. McC. Davidson, M.D., W. M. Will, M.B., J. B. Wood, M.B.

R. B. Lilly, late temporary Captain, is granted the honorary rank of Captain.

Temporary Lieutenant J. M. Ahern, M.B., late Surgeon-Captain, Liverpool Regiment (Volunteers), to be temporary Captain.

V. M. Fisher, M.B., late temporary Captain, is granted the honorary rank of Captain.

Quartermasters and honorary Lieutenants to be honorary Captains: F. Higdon, E. J. Tilbury.

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel D. L. Hamilton to be restored to the establishment on vacating the appointment of Deputy Assistant Director of Medical Services.

Captains (temporary Majors) C. M. Fegen and G. A. Ewart relinquish their temporary rank on alteration in posting, and to be restored to the establishment.

Captain G. L. L. Lawson to be temporary Major whilst in command of a field ambulance.

Captain A. L. Flemming to be restored to the establishment.

Captains seconded for duty with a general hospital: H. H. Markham, T. A. Rowden, M.C., J. Pearson, M.B., W. I. Cumberlidge, F.R.C.S.

Captain A. C. O. Brown relinquishes his commission on account of ill health.

Lieutenant J. R. Clark, M.B., to be Captain.

Quartermasters and honorary Lieutenants to be honorary Captains: D. P. Taylor, J. E. Jones.

VACANCIES.

NOTICES REGARDING APPOINTMENTS.—Attention is called to a Notice (see Index to Advertisements—Important Notice re Appointments) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

BETHNAL GREEN UNION—Temporary Medical Superintendent at the Infirmary, etc. Salary, £550 per annum, and fees estimated at about £75.

BIRKENHEAD AND WIRRAL CHILDREN'S HOSPITAL—House-Surgeon.

BIRMINGHAM GENERAL HOSPITAL—Radiographer.

BRISTOL ROYAL INFIRMARY—(1) House-Physician; (2) House-Surgeon. Salary, £120 per annum.

BURY INFIRMARY—Junior House-Surgeon. Salary, £150 per annum.

DORCHESTER: DORSET COUNTY HOSPITAL—Senior Student to act as House-Surgeon. Salary, £125 per annum.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—Resident Medical Officer. Salary, £150 per annum.

LEICESTER POOR LAW INFIRMARY—Resident Medical Officer. Salary, £300 per annum.

LONDON COUNTY COUNCIL—Assistant Organizers of Children's Care Work. Salary on permanent staff £100 per annum, rising to £130, and temporary £2 a week.

MAIDSTONE: WEST KENT GENERAL HOSPITAL—Assistant House-Surgeon. Salary, £125 per annum.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury.—Resident Medical Officer (lady). Salary, £200 per annum.

MANCHESTER ROYAL INFIRMARY—(1) Resident Surgical Officer; (2) Assistant Resident Surgical Officer; (3) Accident Room House-Surgeon; (4) Resident Medical Officer at Central Branch. Salary for (1) £225 per annum, and for (2), (3), and (4) £200 per annum.

NETLEY: WELSH HOSPITAL—Medical Officer for Surgical Wards. Salary, £400 per annum.

NORTHAMPTONSHIRE SANATORIUM, Cretton.—Medical Superintendent. Salary, £300 per annum, rising to £350.

NORTH EASTERN HOSPITAL, St. Ann's, Tottenham.—Lady Assistant Medical Officers. Salary, £7 7s. per week.

NOTTINGHAM CHILDREN'S HOSPITAL—Resident House-Physician and Anaesthetist. Salary, £250 per annum.

PADDINGTON GREEN CHILDREN'S HOSPITAL, W.—Lady Resident Medical Officer. Salary, £160 per annum.

PRESTON ROYAL INFIRMARY—Resident Medical and Surgical Officer. Salary, £120 per annum.

READING: ROYAL BERKSHIRE HOSPITAL—House-Surgeon. Salary, £275 per annum.

ROTHERHAM HOSPITAL—Junior House-Surgeon. Salary, £150 per annum.

ROYAL EYE HOSPITAL, St. George's Circus, S.E.—House-Surgeon. Salary, £150 per annum.

SURREY COUNTY COUNCIL—Medical Officers for Mother and Infant Welfare and School Work. Salary, £400 per annum, rising to £450.

CERTIFYING FACTORY SURGEON.—The Chief Inspector of Factories announces the following vacant appointment: Bangor (Carnarvon).

MEDICAL REFEREE.—The Home Secretary announces a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for County Court Circuit No. 9, and to be attached more particularly to the Stockport, Ashton-under-Lyne, and Stalybridge and Hyde County Courts. Applications to the Private Secretary, Home Office, by November 23rd, 1917.

To ensure notice in this column—which is compiled from our advertisement columns, where full particulars will be found—it is necessary that advertisements should be received not later than the first post on Wednesday morning. Persons interested should refer also to the Index to Advertisements which follows the Table of Contents in the JOURNAL.

APPOINTMENTS.

EATON, O., M.R.C.S., L.R.C.P.Lond., Medical Officer of the Bingham Union Workhouse.

PARKINSON, W. H., M.D., D.P.H., Medical Officer of Health to the Basford Rural District Council, Nottingham.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTH.

DEVANE.—November 3rd, 1917, at 1, Upper Hartstonge Street, Limerick, the wife of J. P. Devane, M.D., F.R.C.S., of a son.

DEATHS.

McVAIL.—At 3, St. James's Terrace, Glasgow, on the 4th inst., Sir David Caldwell McVail, M.B., F.R.F.P.S.G.

O'KELLY.—On October 30th, Sarah (Sallie), the dearly beloved wife of Captain Fitzgerald O'Kelly, R.A.M.C., of Cross Lodge, Boldon, Newcastle-on-Tyne, aged 33. R.I.P.

RANDALL.—John Beaufort Randall, Captain R.A.M.C. (M.B. and M.S.Lond., M.R.C.S. and L.R.C.P., B.Sc.), younger son of Emma and Wyndham Randall, Surgeon, Brigden, Glam. Killed in action in France, October 31st, 1917, aged 28 years.

STERLING.—On October 16th, 1917, at a Nursing Home in London, in his 58th year, Robert Sterling, M.B., B.S., M.A., Captain R.A.M.C., and Canon of St. George's Collegiate Church, Jerusalem. For twenty-four years C.M.S. Missionary at Gaza, Palestine.

DIARY FOR THE WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.—8.30 p.m.—Discussion on "The Value and Limitations of Sanatorium Treatment for Tuberculosis." (a) Introduction by Dr. T. D. Lister. (b) As Regards the Well-to-do—Dr. David Lawson. (c) The Middle Classes—Dr. Noel Bardswell. (d) The Working Classes—Dr. Wilfred O'Meek. To be continued on November 19th.

TUESDAY.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.—5 p.m., First FitzPatrick Lecture by Dr. Arnold Chaplin: Medicine in England during the Reign of George III.

THURSDAY.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.—5 p.m., Second FitzPatrick Lecture by Dr. Arnold Chaplin: Medicine in England during the Reign of George III.

ROYAL COLLEGE OF SURGEONS, Lincoln Inn Fields, W.C.—3 p.m., Annual meeting of Fellows and Members.

FRIDAY.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos Street, W.—5.30 p.m., Dr. A. T. Ozard: Some Sanitation Problems of the Sugar Estates and Villages of British Guiana. Dr. A. J. Chalmers and Dr. Raino Pekola: *Enteromonas hominis* da Fonseca 1915. Dr. A. C. Stevenson will show specimens of trypanosomes in the brain of guinea-pigs.

ROYAL SOCIETY OF MEDICINE.—Section of Dermatology: Thursday, 4.30 p.m., Cases. Section of Otolaryngology: Friday, 5 p.m., Address by the President, Dr. H. Banks Davis. Paper by Mr. T. Mark Howell: Ménière's Symptoms; Their Causation and Treatment. Cases. Section of Electro-Therapeutics: Friday, 8.30 p.m., Clinical evening: Cases, radiograms, etc.

CURRENT NOTES.

The New Regulations for Treatment of Discharged Disabled Soldiers and Sailors.

THE recent Conference of Panel Committees after a long discussion passed a resolution approving the action of the Insurance Acts Committee in accepting the new regulations as an experimental arrangement. The resolution was passed by such a large majority as justified the members of the Conference in believing that the regulations would now be accepted by all Panel Committees. This seems not to be the case. The London Panel Committee has issued a circular to practitioners on the panel in London urging them to write to the Insurance Committee refusing to accept discharged disabled soldiers and sailors on the lines laid down in the new regulations. The Panel Medico-Political Union, also, has issued a circular to insurance practitioners generally, urging them to take the same course. The result of the vote taken at the Conference on a motion proposed on behalf of the London Panel Committee was overwhelming against the policy of rejecting the regulations, and can only be interpreted as a decision of the very large majority of Panel Committees in favour of accepting them as a temporary measure—that is to say, of acquiescing in the experiment. The experiment is intended to show whether, and to what extent, discharged disabled men require more attendance than the average insured person, and, therefore, what capitation fee would be suitable to meet their case. If some practitioners refuse to attend on the lines of the new regulations while a large majority accept the terms, the experiment which the Conference approved will be vitiated.

Inquiry into Central Insurance Pool.

In a current note last week it was mentioned that Dr. J. C. Lyth of York had been invited to act on the committee which is to co-operate with the President of the Institute of Actuaries in an inquiry into the composition of the Central Insurance Pool. Dr. Lyth has, however, intimated that his other engagements will not allow him to accept the invitation, and Dr. Peter Macdonald of York has been invited to act in his stead, and has agreed to do so.

PROCEEDINGS OF COUNCIL.

A MEETING of the Council was held at 429, Strand, on October 24th last, when there were present:

Dr. J. A. Macdonald, Chairman of Council, in the chair; Sir T. Clifford Allbutt, President; Mr. E. B. Turner, Chairman of Representative Meetings; Dr. G. E. Haslip, Treasurer; Lieut.-Colonel Sir James Barr, Dr. M. G. Biggs, Lieut.-Colonel R. A. Boiam, Dr. H. B. Brackenbury, Dr. H. J. Campbell, Dr. Francis W. Clark, Major Russell Coombe, Dr. J. Singleton Darling, Dr. Edward J. Dornville, Lieut.-Colonel R. H. Elliot, I.M.S., Captain E. Rowland Fothergill, Dr. A. Fulton, Dr. T. W. H. Garstang, Dr. J. J. Giusani, Dr. T. Duncan Greenlees, Mr. N. Bishop Harman, Dr. I. W. Johnson, Dr. R. Langdon-Down, Major Albert Lucas, Fleet Surgeon F. D. Lumley, R.N., Dr. H. C. Mactier, Major George Parker, Dr. C. E. Robertson, Dr. S. Noy Scott, Dr. F. J. Smith, Dr. W. Johnson Smyth, Dr. W. B. Crawford Treasure, Dr. T. Jenner Verrall, Dr. Claude Wilson, and Dr. O. R. M. Wood.

Apologies.

Letters of apology for non-attendance were sent by Dr. John Adams, Major A. C. Farquharson, Dr. James Green, Dr. John Mills, Lieut.-Colonel J. Munro Moir, Dr. E. N. Nason, Dr. John Stevens, and Major C. S. Young.

Death of Dr. Roberts Thomson.

THE CHAIRMAN reported the death of Dr. John Roberts Thomson, President of the Association at the Bournemouth meeting in 1891, and subsequently President of Council 1899-1901, and was requested to forward to Mrs. Thomson the sympathy of the Council in her bereavement and an appreciation of the valued services rendered by Dr. Roberts Thomson to the Association.

Resignation from Council.

Major J. Livingstone London, representative of the Glasgow and West of Scotland (five County Divisions), Border Counties, and Stirling Branches, wrote resigning his seat on the Council consequent upon his military duties.

Lieut.-Colonel Montgomery-Smith, D.S.O.

The Chairman was requested to forward to Colonel Montgomery-Smith, a former member of Council, a letter of congratulation on being awarded the D.S.O.

FINANCE.

Council Room.

It was decided to carry out certain structural alterations in the Council Room with a view to improving the light and ventilation.

Accounts.

The accounts for the period June 2nd to September 30th, 1917, amounting to £18,221 18s. 7d. were approved, and the Treasurer was empowered to pay the same.

ORGANIZATION COMMITTEE.

Annual Representative Meeting.

THE question of the advisability of altering Article 29, as to the holding of Annual Representative Meetings, has been considered, and the Council is of opinion that it is inadvisable to obtain powers to suspend the Annual Meetings of the Representative Body.

Grants to Branches for 1917.

A further grant of 2s. per head was made to the Dorset and West Hants Branch, and 1s. to the Lancashire and Cheshire Branch. No grant is made to the East Anglian Branch, which had in its possession at December 31st, 1916, including moneys in the hands of Divisions, a balance sufficient to meet its average approved expenditure, and leave the Branch in hand at the end of 1917 a balance equivalent to at least 2s. per Branch member.

Representation of Divisions in Representative Body, 1918-19.

THE Home Divisions are provisionally grouped in constituencies for election of Representatives 1918-19 in the same way as for 1917-18, except that the Dewsbury Division of the Yorkshire Branch is grouped with the Leeds Division of that Branch. This provisional list of constituencies will be forwarded to the Divisions, and if any proposals for alteration are received by January 7th, 1918, the constituencies affected by these proposals will be reconsidered at the January meeting of the Council. Each Oversea Division and Division-Branch which has an Honorary Secretary and the necessary organization is

granted independent representation in the Representative Body 1918-19.

JOURNAL COMMITTEE.

Usefulness of the Journal.

Certain criticisms as to the usefulness of the JOURNAL having been carefully considered, the Council is of opinion that the present form of the JOURNAL on the whole is suitable, and does meet the present needs of the Association, but feels that members would welcome an increase in the number of contributions on clinical subjects. In order to increase the general interest of members the Editor has been requested to develop in the SUPPLEMENT the column of "Current Notes" on the Association work by publishing weekly notes on the work of various committees and subcommittees.

CENTRAL ETHICAL COMMITTEE.

Position of Practitioners Examining Patients of other Practitioners.

With regard to the rules approved by the Annual Representative Meeting 1912, respecting the position of medical practitioners called upon to examine (otherwise than by request of the patient or persons acting on his behalf) patients who are under the care of other practitioners, after consideration of certain suggestions made at the Annual Representative Meeting, 1917, it was agreed that in Rule 1 the word "examination" be not substituted for the word "visit" in each instance, while Rule 5 should not be amended.

PUBLIC HEALTH COMMITTEE.

Ministry of Health.

The Chairman of the Committee, with the consent of the Council, withdrew certain recommendations in view of the fact that the Ministry of Health Committee was conferring with the medical officers of health organizations upon the matter.

MEDICO-POLITICAL COMMITTEE.

Medical Certificates of Incapacity for Work of Munition Workers.

Medical practitioners are urged to refuse to sign the elaborate form of certificate of incapacity for work, issued by the Ministry of Munitions, unless an adequate fee be paid for it. The Annual Representative Meeting, 1917, decided that one shilling was not adequate for that form of certificate.

Lay Persons and the Practice of Medical Radiography.

The Council is of opinion that it is not desirable to encourage the practice of medical radiography by lay persons, except under the direct instructions and supervision of medical practitioners.

Medical Fees for Private Practice.

The Council came to the decision that without prejudice to the sufficiency or otherwise of medical fees before the war, it considers that under present war conditions individual or local collective action in the direction of securing an increase of medical fees is justified.

Medical Motorists and Petrol.

The Medico-Political Committee was instructed to consider the advisability of issuing a badge by the Association to its members for their motor-cars, and, in conjunction with the Chairmen of Council and Representative Meetings, was empowered to take any necessary action in connexion therewith. Should the Committee decide to take the action suggested, the various chief constables throughout the kingdom will be informed.

Postal Medical Officers.

It was referred to the Medico-Political Committee to consider the question of the desirability of the Association taking action with a view to securing an increase in the capitation payment to postal medical officers.

INSURANCE ACTS COMMITTEE.

Conference of Representatives of Local Medical and Panel Committees.

The Chairman of the Committee reported that the Conference on October 18th decided by 113 to 16 to renew its expression of confidence in the Committee as the central negotiating body of the Local Medical and Panel Committees of the country.

HOSPITALS COMMITTEE.

Payment for Treatment of Discharged Disabled Soldiers and Sailors at Voluntary Hospitals.

It will be recommended to the Annual Representative Meeting that where it is possible, without detriment to the claims of the civil population, to give hospital treatment, either as in- or out-patients, to discharged soldiers and sailors for whom a public authority is liable, a charge should invariably be made which shall repay the hospital for cost of working and maintenance, and that in addition £2 2s. per case treated, or alternatively a sum equal to 10 per cent. of the amount paid to the institution for working and maintenance expenses, should be put at the disposal of the medical staff.

CHAIRMEN'S COMMITTEE.

Ministry of Health.

A Special Committee was appointed, in place of the Subcommittee which has hitherto had the matter in hand, to deal with the Ministry of Health question, consisting of, in addition to the officers of the Association, the following practitioners: Dr. John Adams (Glasgow), Dr. E. J. Domville (Exeter), Dr. T. Campbell (Wigan), Mr. N. Bishop Harman (London), Professor A. Bostock Hill (Birmingham), Dr. H. J. Cardale (London), Dr. T. Ridley Bailey (Bilston, Staffs), Dr. Alice Benham (London), Dr. M. G. Biggs (London), Dr. H. J. Campbell (Bradford), Captain E. R. Fothergill (Brighton), Sir Malcolm Morris, K.C.V.O., (London), Dr. J. Kennish (London), Dr. T. W. H. Garstang, and Mr. R. J. Johnstone (Belfast) (to be invited when questions which may concern Ireland are under consideration). The committee is instructed to take action in connexion with the following Minutes of the Annual Representative Meeting, 1917, and to report to the Council:

Minute 104.—Resolved: That a Ministry of Health should be created to take over from the existing Government departments such duties as are concerned with the health of the community and to deal with those duties only.

Minute 114.—Resolved: That the Representative Meeting approves generally the scheme submitted for the establishment of a Ministry of Health, and instructs the Council to consider the amendments presented to the Representative Meeting, or by any Divisions, to present the scheme to the Government, and to secure its acceptance so far as it is found to be possible.

NON-PANEL COMMITTEE.

A Non-Panel Committee was reappointed to consider in what manner the British Medical Association can best promote the interests of members who have not entered into agreements with the Insurance Committees.

The Committee consists of, in addition to the *ex officio* members, Dr. Kennish (Wandsworth), Dr. M. G. Biggs (Battersea), Dr. J. Stevens (Edinburgh), Dr. Howell (Putney), Dr. H. B. Densham (Stockton), Dr. Nason (Nuneaton), Dr. H. B. Brackenbury (Stroud Green, N.), Dr. Charles Buttar (London), with power to co-opt not more than four additional members.

CANDIDATES.

There were 145 candidates for membership of the British Medical Association and they were duly elected.

INSURANCE.

NATIONAL HEALTH INSURANCE AMENDMENT BILL.

THE National Insurance Amending Bill, introduced in the House of Commons by Sir Edwin Cornwall, is a measure of forty-five clauses and five schedules. The bill finds its origin in the report of a Departmental Committee, of which Sir Gerald Ryan was chairman, appointed last year to consider what amendments in the financial scheme were desirable upon experience of the administration of the sickness, disablement, and maternity benefits. The bill does not altogether follow the recommendations of the report as regards finance; it varies them, and it also makes proposals to improve the working of National Insurance. Thus it deals with (1) financial provisions, (2) simplification of machinery, and (3) additional powers.

FINANCIAL PROVISIONS.

The Ryan Committee found that as regards men, and even as regards women generally, the financial basis of the Act was sound, but that the claims of married women

had proved to be in excess of the actuarial allowances. When they framed the scales the actuaries had no experience of the insurance of women. The Ryan Committee proposed an additional grant of £150,000 per annum from the Exchequer, but, though this was allocated by Parliament some time previously, it was held up. The bill proposes the recognition of this grant and of the further sum of £250,000 per annum. The Ryan Committee proposed to extend the intervals between valuations of societies from three to six years; the bill proposes that the normal intervals shall be five years instead of three years, and the men's Special Reserve Fund to provide against the remote effects of war service upon the health of insured men is dropped.

Under the existing Acts there is set apart from each weekly contribution for an insured woman the sum of 1½d. for the redemption of reserve values. The bill proposes that this sum shall be reduced to 1¼d. and that the difference of ½d. per contribution shall be released to provide an additional margin to approved societies for their ordinary benefit fund.

The proportion of each weekly contribution, which will in future be set aside by the Commissioners, will be 1¼d. for men and 1½d. for women, but the bill proposes that ¾d. in the case of men and ¾d. in the case of women shall be retained by the Commissioners for the purpose of constituting two new reserve funds known as the Contingencies Fund and the Special Risks Fund.

A third new fund is created called the Women's Equalization Fund. The income of this fund is provided out of Exchequer moneys. It is to be constituted retrospectively, and for the years 1913-16 inclusive its income will be derived from an application of the £500,000 special grant for women voted by Parliament in 1914, supplemented, if necessary, by a payment from the accumulated reserve values. For 1917 and subsequent years the whole income will be provided out of the new Exchequer grants which the Government has undertaken to find.

Application of Funds.

The Women's Equalization Fund is to be applied in assisting approved societies in meeting their liabilities in respect of the sickness claims. A scheme is to be framed by the Joint Committee under which a sum not exceeding 8s. will be paid to a society for every married woman member to be available for the payment of benefits. Although the money is found by the Exchequer, the payment will be treated as a payment from contributions, and accordingly societies will have a claim to an additional two-ninths from State moneys.

The Contingencies Fund will be apportioned to societies in proportion to the number of contributions paid in respect of their members. It will be available for meeting any deficiency of the society or of the branches, and no part of the surplus of any society or branch disclosed on a valuation will be applied in meeting any deficiency in any other society or branch. Thus each society or branch will have its own Contingencies Fund, the object of which is to meet its own deficiency. Any sum not required to meet the deficiency must be carried forward until after the second valuation; thereafter any balance more than necessary for a reasonable reserve may be applied as a surplus available for additional benefits under Section 37 of the 1911 Act. There are provisions to guard against maladministration.

The Special Risks Fund, the income of which is derived, as explained above, from a proportion of the contributions retained by the Commissioners, will be supplemented by the annual parliamentary payment of £150,000, to which reference has already been made, and any interest which the accumulated fund may earn will be available to make good any deficiency not met out of the Contingencies Fund of a society:

(1) Due in whole or in part to an abnormal rate of sickness attributable to—

- (a) Nature of employment;
- (b) Environment;
- (c) Physical condition of the members;
- (d) Any epidemic disease; or

(2) Due to any other special cause beyond the control of the Society or Branch.

It is laid down in the bill that the National Health Insurance Joint Committee shall, if requested by a society, appoint an independent body to investigate the circumstances of a deficiency.

SIMPLIFICATION OF MACHINERY.

It is proposed to abolish for the future the voluntary class of contributors, but to admit to a new class of voluntary contributors all the present class as at November 5th, 1917, and also all persons who have been compulsorily insured for 104 weeks, and who give notice that they desire to be voluntary contributors. This qualification of two years comes in place of a previous one of five. The new class will pay the ordinary employed rate of contribution, and will receive the ordinary benefits, except that a voluntary contributor resident in Great Britain who is not entitled to receive medical benefit because his income exceeds £160 per annum will be entitled to a rebate of contribution of 1¼d.

It is proposed in future that where workers receive rates of remuneration of 2s. or less a working day, the employer shall pay the full contribution, and may claim repayment of the amount advanced. The contribution payable by an employer for an employee who holds a certificate of exemption at present varies with rate of remuneration. It is proposed in future that in every case the contribution shall be 3d. per week.

No claim can be made at present for maternity benefit until an insured person has been 26 weeks in insurance and paid 26 contributions, or, in the case of a voluntary contributor, 52 weeks and 52 contributions. The bill proposes a uniform period of 42 weeks and the payment of 42 contributions. The voluntary contributor will receive a concession of six weeks and six contributions, and the approved society in the case of an ordinary contributor will receive a measure of protection against "constructive" entrance to insurance for the period of drawing maternity benefit. It is felt that the addition of 16 weeks and 16 contributions will be an effective deterrent to a growing tendency to engage in work for a few days in order to secure maternity benefit.

Much trouble has been caused to societies by failure to give timely notice of sickness or disablement. It is proposed that unless notice is given within three days of the commencement of the incapacity, benefit shall ordinarily be payable only from the date of notice.

Where an insured person ceases to be employed or to pay contributions as a voluntary contributor he will for twelve months after the last contribution remain an insured person entitled to ordinary benefit, and to medical and sanatorium benefits to the end of the year in which he ceases to be insured. Thus, a person who drops out of insurance in January, 1918, will receive ordinary benefits till January, 1919, and medical benefit to December 31st, 1919. If, during any part of the twelve months, he is incapable of work by incapacity and gives notice to his society, the period of incapacity will be added to the twelve months. If such a person again enters insurance he will be treated as a new entrant.

Another fresh provision touches the right of an insured person to change from one society to another. Obviously the loss of a substantial number of members by such transfers might imperil the stability of the society, and the desire to change may be due to the resentment of reasonable inquiries. The bill proposes expressly to allow insured persons to terminate membership, but to do so only at times prescribed by the Commissioners, and there are various other safeguards against the risks indicated.

Clause 20 amends the law in respect of contributors who are inmates of hospitals, etc., and provides for the payment of any benefits which accrued during such residence being paid to the insured person's representatives in the event of his death in the institution.

The present complicated provisions of the Act under which a woman on marriage has various options are proposed to be repealed, and in place of these options it is proposed to provide for a marriage benefit of £2 with a right to medical and sanatorium benefit to the end of the year following that in which she ceases to be employed.

This provision is in effect on the lines of the surrender-value provision which is afforded under ordinary insurance policies.

One clause of the bill varies the existing powers of the Insurance Commissioners in regard to the withdrawal of the names of medical practitioners from lists. The text is as follows:

(1) Where the Insurance Commissioners in pursuance of their powers under section fifteen of the principal Act remove

the name of any medical practitioner from any list of medical practitioners prepared under the said section, they may, if they think so to do, remove his name from all or any of the other lists so prepared in which it is at the time included, and until such time as the Commissioners direct to the contrary that practitioner shall be disqualified for inclusion in any other list, whether in England, Scotland, or Wales, in which his name was not then so included or from which it was then removed.

(2) Regulations made under section fifteen of the principal Act may, subject to such modifications as may be prescribed, provide for the application to inquiries held under paragraph (b) of subsection (2) and paragraph (b) of subsection (5) of the said section respectively of any of the provisions of the Arbitration Act, 1889, relating to the costs of an arbitration, the attendance of witnesses, and the production of documents, and the regulations may provide that the costs of any inquiry and of the finding thereon shall be in the discretion of the Commissioners instead of in the discretion of the person holding the inquiry.

The special provisions of Section 45 of the 1911 Act regarding aliens are repealed, and it is proposed that they shall be treated as ordinary insured persons.

Section 47, which provides a special rate of contribution in cases where an employer has undertaken to pay wages during sickness, is repealed.

Inmates of reformatory or charitable institutions who receive maintenance and medical attendance might hitherto on the application of the managers be exempted from insurance, their benefits being suspended. It was a condition of the exemption that the institution should, in the event of their leaving the institution, provide the capital sum necessary to put them in a position to obtain the ordinary benefits. It has been found that the provision is difficult to work, and that under the amended scheme of arrears such cases are best treated under the general provisions. The section is repealed.

Section 63 of the original Act, which dealt with the question of excessive sickness, is amended. It is proposed that where an allegation of excessive sickness is made by an approved society or insurance committee,

the society or committee shall, in the event of their failing to arrive at an agreement with the person or authority concerned refer the matter with a statement in support of the allegation to the Insurance Commissioners, and shall not make an application for an inquiry unless the Commissioners are of opinion that a *prima facie* case for an inquiry is disclosed, and authorize such an application to be made.

In the Act the definition of "excessive sickness" is "in excess of the average expectation of sickness by more than 10 per cent." The bill proposes that for these words shall be substituted "in excess of the amount of sickness which, in the opinion of the person holding the inquiry, ought, in all the circumstances of the case, to have occurred."

Further powers are to be conferred on the Commissioners to make regulations dealing with a number of matters, including medical certification and the cost of administration of medical benefit.

VACANCIES.

NOTICES REGARDING APPOINTMENTS.—Attention is called to a Notice (see Index to Advertisements—Important Notice re Appointments) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

BRADFORD CITY.—Temporary Assistant School Medical Officer. Salary, £8 8s. per week.

BRISTOL ROYAL INFIRMARY.—(1) House-Physician; (2) House-Surgeon. Salary, £120 per annum.

BURY INFIRMARY.—Junior House-Surgeon. Salary, £150 per annum.

DERBY. **DERBYSHIRE ROYAL INFIRMARY.**—House-Surgeon. Salary, £200 per annum.

DORCHESTER. **DORSET COUNTY HOSPITAL.**—Senior Student to act as House-Surgeon. Salary, £125 per annum.

GLAMORGAN COUNTY COUNCIL.—Temporary Woman Medical Officer in connexion with Medical Inspection of Public School Children. Salary, £200 per annum.

HAMPSTEAD GENERAL HOSPITAL. Haverstock Hill, N.W.—Resident House-Physician. Salary, £200 per annum.

HOSPITAL FRANCIS. Shaftesbury Avenue, W.C.—Anaesthetist. Honorarium, £25 per annum.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST. Brompton, S.W.—House-Physician. Honorarium, 50 guineas for

INVERNESS. **NORTHERN INFIRMARY.**—House-Surgeon. Salary, £100 per week and £1 ls. additional as war bonus.

LEICESTER ROYAL INFIRMARY.—House Surgeon. Salary, £250 per annum.

LONDON LOCK HOSPITAL. Dean Street, W.—House-Surgeon. Salary, £150 per annum.

NETLEY. **BRITISH RED CROSS HOSPITAL.**—Anaesthetist.

NEW HOSPITAL FOR WOMEN. Euston Road, N.W.—(1) House-Physician. (2) Obstetric Assistant. (3) Two House-Surgeons. (4) Resident Medical Officer at House of Recovery, New Street. (5) Clinical Assistants and Anaesthetists. Salary for (1), (2), and (3), £50 per annum, and for (4) £60 per annum.

NORTHAMPTONSHIRE SANATORIUM. Creaton.—Medical Superintendent. Salary, £300 per annum, rising to £350.

NOTTINGHAM CHILDREN'S HOSPITAL.—Resident Lady House-Physician and Anaesthetist. Salary, £250 per annum.

NOTTINGHAM GENERAL HOSPITAL.—Casualty House-Surgeon (female). Salary at the rate of £250 per annum.

PRESTON ROYAL INFIRMARY.—Resident Medical and Surgical Officer. Salary, £120 per annum.

QUEEN MARY'S HOSPITAL FOR CHILDREN. Carshalton.—Temporary Assistant Medical Officer. Salary, £7 7s. a week.

ROTHERHAM HOSPITAL.—Junior House-Surgeon. Salary, £150 per annum.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Milroy Lecturer.

SUFFOLK HOSPITAL. Ampton Hall, near Bury St. Edmunds.—Assistant Resident Medical Officer. Salary, £200 per annum.

SUNDERLAND. **CHILDREN'S HOSPITAL IN CONNEXION WITH ROYAL INFIRMARY.**—Resident Medical Officer. Salary, £200 per annum.

TYRONE COUNTY COUNCIL.—Tuberculosis Medical Officer. Salary, £50 per annum.

WARWICK. **WARWICKSHIRE COUNTY COUNCIL.**—Assistant County Medical Officer of Health. Salary, £325.

WINCHESTER. **ROYAL HAMPSHIRE COUNTY HOSPITAL.**—Assistant Resident Medical Officer. Salary, £150 per annum.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House-Surgeon. Salary, £200 per annum.

To ensure notice in this column—which is compiled from our advertisement columns, where full particulars will be found—it is necessary that advertisements should be received not later than the first post on Wednesday morning. Persons interested should refer also to the Index to Advertisements which follows the Table of Contents in the JOURNAL.

APPOINTMENTS.

KIRKALDY. W. B., M.D. Edin., District Medical Officer of the Cannock Union.

ST. THOMAS'S HOSPITAL.—The following house appointments have been made:—Casualty Officers and Resident Anaesthetists: F. C. Odling, B.A. Cantab., M.R.C.S., L.R.C.P.; J. G. McCann, M.R.C.S., L.R.C.P.; C. V. Issard, M.R.C.S., L.R.C.P.; H. I. Mariner, Resident House-Physicians: W. E. Le Gros Clark, M.R.C.S., L.R.C.P.; J. S. Elciff, M.R.C.S., L.R.C.P.; E. A. Gibb, B.A. Cantab., M.R.C.S., L.R.C.P.; E. D. Russell, M.R.C.S., L.R.C.P. Resident House-Surgeons: T. F. M. Dilworth, M.B., B.Ch., B.A.O., N.U.I.; A. H. Hilmy, M.R.C.S., L.R.C.P.; F. R. G. Hief, B.A. Cantab.; R. Calvo, Resident House-Surgeon to Block 8; R. A. Walker, Resident Obstetric House-Physician; F. N. Reynolds, M.R.C.S., L.R.C.P.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTH.

COFFEY.—On November 2nd, at 21, Storey Square, Barrow-in-Furness, the wife of Lieut.-Colonel Coffey, R.A.M.C., a daughter.

MARRIAGE.

ALDRIDGE-KNEVITT.—On Monday, November 5th, 1917, at Emanuel Church, Plymouth, by the Vicar, the Rev. Dr. Flynn, Charles Aldridge, M.D., of Belle Vue House, Plymouth, S. Devon, to Edith Knevitt, of 4, Thom Park Terrace, Mannamoad, Plymouth.

DIARY FOR THE WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON. 11, Chandos Street, W.1.—8.30 p.m., Resumed Discussion on the Value and Limitations of Sanatorium Treatment for Tuberculosis, by Sir Douglas Powell, Bt., Sir Arthur Newsholme, Dr. F. R. Walters, Dr. A. Niven Robertson, Dr. Grace Calvert, Dr. J. J. Perkins, and others.

FRIDAY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. Lincoln's Inn Fields, W.C., 5 p.m.—Professor A. Keith: Principles of Orthopaedic Treatment. Lecture I. Principles Enunciated and Applied by John Hunter.

ROYAL SOCIETY OF MEDICINE.—Tuesday, 5 p.m., General meeting of Fellows. Section of History of Medicine: Wednesday, 4.30 p.m., Exhibition of Books, etc. 5 p.m., Conjoint meeting with the Folk Lore Society. Dr. R. R. Marett: The Medicine Man. Section of Study of Disease in Children: Friday, 4.30 p.m., Cases.

POST-GRADUATE COURSES AND LECTURES.

NORTH-EAST LONDON POST-GRADUATE COLLEGE. Prince of Wales's General Hospital, Tottenham, N.15.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE. Hammer-smith, W.

DIARY OF THE ASSOCIATION.

Date. Meetings to be Held.

CURRENT NOTES.

Repairs and Spare Parts for Doctors' Cars.

THE Priority Branch of the Ministry of Munitions has sent to the British Medical Association a copy of a circular addressed by the department to all makers of motor cars and cycles with reference to the supply of spare parts, and the execution of repairs to motor vehicles of their manufacture. The circular authorizes such manufacturers to supply spare parts, or execute repairs to motor cars or motor cycles used by doctors, dentists, or veterinary surgeons, necessarily for professional purposes, without application to the Ministry of Munitions, where the total value (including the value of labour as well as of material) does not exceed £10 at any one time for any one vehicle. The manufacturer must furnish to the Priority Department a monthly return of all orders executed by him under this authorization, accompanied by the written declarations of the users. The declaration must accompany each order, and be written in the following form:

I hereby declare that
the car Regn. No.
cycle
falls under the class of vehicle enumerated in Class (1).

The proviso is made that no order may be executed under this authority if such would directly, or indirectly, interfere with, or delay, the progress of any work in Class "A." If medical practitioners are unable to obtain their requirements from the makers of their cars under the above conditions, or if they need repairs and spare parts exceeding £10 in value, they should then, and then only, apply to the Priority Branch of the Ministry of Munitions, 1, Caxton Street, Westminster, S.W.1, for assistance, stating their requirements and the reasons for urgency.

A Motor Car Badge for Members of the Association.

In view of the new regulations restricting the use of motor cars to persons engaged in specified duties, the Council of the British Medical Association at its last meeting decided that a badge of distinctive character should be issued to members of the Association for affixing to their cars. A badge has therefore been designed, and will shortly be ready for issue to members who desire it. It will be of paper, gummed for attaching to the inside of the wind screen, and printed with the caduceus within the words "British Medical Association." It will be issued at the cost of 1s. to any member who undertakes to use it only when his car is engaged on professional or other duties within the regulations. Steps will be taken to bring it to the notice of all police authorities, who, in view of its significance and the conditions under which it is issued, will, it is hoped, give general instructions that cars displaying it are to be held up for inquiries as little as possible. The badge is expected to be ready for use by

the new year, and further particulars as to its issue will be given in this column, and also by notice to secretaries of Branches and Divisions.

Conditions of Dental Practice.

The Medico-Political Committee has accepted on behalf of the British Medical Association the invitation of the recently appointed Departmental Committee on the working of the Dentists Act, 1878, and matters connected therewith, to submit a memorandum dealing with (a) the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not qualified under the Dentists Act, and (b) the extent of the inadequacy of the supply of qualified dentists and dental surgeons. Valuable information has been obtained from Branches and Divisions, and from individual medical practitioners, which is being incorporated in a memorandum for submission to the Departmental Committee, and will, if required, be supported by oral evidence of witnesses on behalf of the Association.

INSURANCE.

REMUNERATION UNDER THE INSURANCE ACTS.

DEPUTATION TO THE INSURANCE COMMISSIONERS.

A DEPUTATION of members of the Insurance Acts Committee of the British Medical Association was received by the Insurance Commissioners on November 15th. The deputation consisted of Dr. H. B. Brackenbury, Dr. T. Campbell, Dr. H. G. Cowie, Captain E. R. Fothergill, Dr. P. V. Fry, Dr. G. G. Genge, Dr. Hugh Jones, Dr. J. Ratcliff-Gaylard, Mr. E. B. Turner, Dr. J. Williams-Freeman, the Medical Secretary, and the Deputy Medical Secretary of the British Medical Association.

The deputation was received by Sir Robert Morant, K.C.B., Chairman of the National Insurance Commission (England), who was accompanied by Dr. J. Smith Whitaker, Deputy Chairman, Sir James Leishman, Chairman of the Insurance Commission (Scotland), and Dr. Meredith Richards, Deputy Chairman of the Insurance Commission (Wales).

For the sake of convenience the various points discussed are dealt with under the minutes embodying the resolutions passed at the Conference of Representatives of Local Medical and Panel Committees held on October 18th, and cross-headings have been introduced.

Insurance Acts Committee Representative of Local Medical and Panel Committees.

Dr. Brackenbury opened the discussion by referring to the resolution embodied in Minute 39, renewing the mandate of the Insurance Acts Committee to represent the Local Medical and Panel Committees in central negotiations, which the Conference had passed with thirteen dissentients. He pointed out that the resolution was a vote of confidence in terms substantially more emphatic than those of similar resolutions in previous years

Central Pool.

On Minute 67, asking for an inquiry by representatives of the Committee assisted by an independent actuary into the method of composition of the Central Pool, Sir R. Morant stated that the Commissioners and the Government Actuary were fully prepared to fall in with the suggestion made. Dr. Brackenbury announced that six members had been selected to deal with the matter and that the President of the Institute of Actuaries had been invited and had agreed to confer with the Government Actuary and report on the subject. It was agreed that the names of the six members should be furnished to the Commissioners, and that a preliminary discussion as to procedure should take place as soon as possible.

On Minutes 58, 59, and 60, dealing with questions of remuneration, Dr. Brackenbury stated that there were three distinct points in connexion with remuneration:

1. The composition of the Central Pool.
2. The actual rate of remuneration.
3. The method of distribution of the Central Pool among areas and among doctors.

The first point was the subject matter of Minute 67, already dealt with. With regard to point 3, the method of distribution was one of the principal grievances of the profession, and various resolutions of Panel Committees bearing on it had been referred by the Conference to the Insurance Acts Committee for consideration. That Committee hoped that the Commissioners would agree to some arrangements for discussion and investigation of this subject similar to those proposed for dealing with questions arising under Minute 67.

Sir R. Morant agreed that the matter might well be taken up in some such manner as was suggested, and it was further agreed that the necessary arrangements should be made as soon as possible.

Actual Amount of Remuneration.

As regards the second point, amount of remuneration, Dr. Brackenbury pointed out that various methods of increasing the amount might be suggested, but that the Insurance Acts Committee had been instructed to approach the Commissioners particularly with reference to an increase of the capitation fee. The reasons for this application were various, but the main consideration was the actual increase in the cost of carrying on practices and in the cost of living; 7s. was not worth what it had been when the bargain was made in 1912, and it was certain that the profession would never have made such a bargain if it had anticipated present conditions.

Another point which he pressed strongly was that the Government should not aim at paying the smallest amount for which they could get a doctor to undertake the work. The standard of services given by many insurance practitioners was far above the minimum standard, and they felt that the present capitation fee (which, having regard to the temporary resident calculations, corresponded to attendance fees at approximately the rate of 2s. 4½d. per visit and 1s. 5d. per attendance at the surgery) was altogether inadequate. The fact that in certain areas a high standard of work was not fully maintained by every practitioner was an argument in favour of rather than against raising the rate of remuneration. The profession felt that the matter was urgent. They did not press it last year, but in refraining from doing so they stated definitely that their willingness to continue on the existing basis must be regarded as a contribution by the profession to the country as a whole. The Conference now asked that the capitation fee paid for medical attendance in connexion with medical and sanatorium benefits be raised from 7s. to 10s.

Sir R. Morant agreed that it was the desire of the Government as of the profession to secure an effective medical service, but it was another question whether increased payment would alone or would necessarily secure this. It was, however, most important to know whether the present application was based on the diminished value of money, or whether it was put forward on the ground that, apart from war conditions or any other considerations which might prove to be temporary, the present rate of remuneration must be regarded as inadequate. If put forward on the latter grounds it could only be considered in connexion with a general revision of all the conditions of service, a matter on which obviously a final decision could not be reached by the Government

in any short time, if indeed at all under existing conditions. But if it were on grounds of war conditions the submission of this question to the Government would not involve such difficulties.

After some discussion it was agreed by the deputation that the present application should be submitted to the Government as one based on war conditions; this would, of course, be without prejudice (whether as regards the profession or the Commissioners) to any future consideration of the general question of the proper rate of remuneration for insurance practice.

Further points mentioned by the deputation in connexion with the question of increased remuneration were: (a) The heavy expenses under normal conditions of rural practitioners; (b) the increased number of women as compared with men in insurance; and (c) the number of children of well-to-do parents who had entered munition works and other industrial employment for the first time.

With regard to the second of these points, Sir R. Morant stated that the sickness incidence of women had been steadily decreasing, and suggested that though this was not an infallible criterion of the extent of the liability imposed by women as a class upon doctors, it afforded indications which had to be taken to some extent into account in making any estimate of that liability. Members of the deputation, while agreeing that this datum must necessarily be considered, expressed the opinion that it would be an extremely unreliable one from which to draw conclusions as to the amount of medical attendance required.

Invalided Soldiers: Mileage.

On Minute 30, objecting to the mileage allowance offered for attendance on discharged sailors and soldiers, Dr. Brackenbury stated that the Conference of Panel Committees had emphatically taken the view that the scheme of treatment of invalided soldiers was vitiated by the mileage arrangements. It was alleged that in many cases a rural doctor was actually at loss in attending cases.

Sir R. Morant suggested that there was no difference in principle between this question and the question of mileage in the case of ordinary patients, on which it was understood that the Committee had also received instructions to approach the Commissioners.

Rural Practitioners: Mileage.

Dr. Williams-Freeman, on behalf of rural practitioners, gave figures showing the cost per mile of motor travelling under pre-war and present conditions, and referred to the mileage rates paid by the Home Office and the War Office. After further discussion, it was agreed that the matter was one to be considered as a whole, and not merely from the point of view of the invalided soldiers arrangement.

Dr. Brackenbury stated that the matter was very urgent in view of the additional grievance that it was felt was being imposed by the mileage allowance under the new regulations, and Sir R. Morant agreed that it might be more quickly disposed of than the main question of increased remuneration, and stated that he hoped some decision could be announced in the course of a few weeks.

It was agreed that certain detailed figures which had been given by members of the deputation having rural practices should be forwarded to the Commissioners in the next few days, and that specific modifications should then be worked out promptly for consideration.

THE CENTRAL POOL AND THE INVALIDED SOLDIERS' FUND.

CHESTER.

The Honorary Secretary of the Cheshire Local Medical and Panel Committees was good enough to forward to us on November 7th a copy of an important correspondence between that Committee and the Commissioners, dealing with the remuneration of panel practitioners and the Invalided Soldiers' Fund. The Committee first informed the Commissioners that it had resolved to advise its constituents to give notice at the proper time of the termination of their agreements on the present terms at the end of the year. The Committee proposed to advise its constituents to accept service (a) at a capitation fee of 10s., and (b) on payment per attendance for invalided soldiers and sailors at the schedule rates stated in the new regulations, with a scale for operations based on

the Poor Law scale, but with a more comprehensive list of operations, and with the proviso that such payment per attendance must be the actual payments of the sums named in the agreed tariff, and not on any dividend basis or other indirect method of computation. The secretary of the Committee then set out at length the reasons which had influenced the Committee in arriving at the above decisions, and expressed doubts in particular as to the making up not only of the General Medical Benefit Fund, but the Invalided Soldiers' Medical Fund, which the Commissioners were requested to explain. The reply of the Commissioners, dated October 5th, commences by stating that they were not then in a position to deal with the general revision of the terms of remuneration of panel practitioners pending the Conference of Panel Committees. With regard to the scale of fees for services rendered to invalided soldiers the Commissioners state that it was submitted in detail to all Local Medical and Panel Committees, when it was adopted in the case of temporary residents and met with general approval. The remainder of the Commissioners' letter is as follows:

With regard to the application of the temporary resident dividend rate in ascertaining the payments to be made in respect of the services to disabled men treated under the special arrangements, I am to state that the sole object of this procedure is to apply to the treatment of discharged soldiers the rate per service applicable to ordinary insured persons and does not in any way limit the number of services for which the doctor will be paid. In order to remove any misunderstanding on the point, I am to explain that the payments to be made in respect of services to disabled men are in no way restricted to the amount in the Invalided Soldiers' Medical Fund. The position may perhaps be made clearer by means of a concrete illustration. Assuming for the purpose, that the aggregate of the doctors' accounts for services to disabled men when calculated on the scale contained in the regulations is £100,000 and the temporary resident dividend rate for the year is 95 per cent., the actual payment to the doctors will be £95,000 irrespective of the amount in the Invalided Soldiers' Medical Fund. If, as is likely to be the case, the amount in the latter is less than £95,000, the balance will be found by the Exchequer.

With reference to the remarks in your letter relating to the constitution of the General Medical Benefit Fund and Invalided Soldiers' Medical Fund, I am to state that the Committee appear to be under a substantial misapprehension as to the actual position.

The latter part of your letter suggests that while 9s. a head for invalided sailors and soldiers is clearly to be taken out of the General Medical Benefit Fund there is a doubt as to whether 9s. a head for such persons had previously been paid into that fund.

It cannot be too clearly stated that there is no justification for any such doubt as to the constitution of the General Medical Benefit Fund.

The doubt has apparently arisen in the case of members of approved societies who submit no stamped contribution cards. It is unnecessary, therefore, in this letter to deal in detail with any of the other classes. It may be mentioned, however, that all insured disabled men who do not belong to approved societies become automatically members of the Navy and Army Fund, and the 9s. in their case is paid by the fund for the solvency of which the Exchequer is liable. The number of such men is definitely ascertainable, and no difficulty therefore arises in their case in calculating the amount payable to the General Medical Benefit Fund.

Turning to the members of approved societies who submit no contribution cards, in respect of whom the doubt has arisen, the 9s. in their case (less the State proportion) is payable by societies, notwithstanding the absence of stamped contribution cards.

The Commissioners have stated in paragraph 43 of Memo. 229 I.C. that they fully recognize their responsibility for the proper constitution of the General Medical Benefit Fund and that they have no other purpose in view than to arrive as accurately as is humanly possible at the sum of money due to the doctors.

In paragraphs 29-31 of the Memo. it is explained that normally society members who are permanently incapacitated are a set-off in a central pool against excess credits in respect of other classes of insured persons. But in paragraph 39 the special procedure adopted in the 1915 medical benefit settlement is set out, and this course was again adopted at the instance of the medical profession in 1916. It is expressly stated in this paragraph that the total charges for 1915 against societies in respect of medical benefit were calculated on the basis of the charges for 1914, adjustments being made *inter alia* in respect of the number of insured persons discharged from the navy and army; these adjustments have the effect of adding the proper credits to the central pool in respect of these discharged persons.

It follows therefore that the proper credit at 9s. per head is paid into the Medical Benefit Fund annually in respect of discharged sailors and soldiers, and that societies are charged in respect of these men if they are members of societies and the Navy and Army Fund if they are not.

Insurance calculations affecting several millions of insured persons are of necessity complicated, but it should be apparent

from the extracts of Memo. 229 I.C. to which reference has been made that the original formula in accordance with which the Central Medical Pool is calculated has not been followed blindly, but has in fact been the subject of adjustment to meet the conditions created by the return of disabled soldiers and sailors to insurance, entitling them to medical benefit, and that it will, in accordance with the general undertaking given by the Commissioners in paragraph 42 of the Memo., continue to be adjusted either in that respect or in any other in which revision is called for, in order that the doctors may in fact receive what is due to them.

In reply to the above letter from the Commissioners the Panel Committee wrote on October 29th, reaffirming its resolution about the 10s. capitation fee, and expressing the hope that, now that the Conference had sat, the Commissioners would deal with the matters raised, in view of the near approach of the date when notices to terminate the agreement of panel services must be sent in. The Committee further informed the Commissioners that no system of capitation can be satisfactory to the profession "unless it be made upon the actual lists upon some given date in arrears, and not as at present on a system of estimate and conjecture." A further letter was sent by the Panel Committee on November 6th, asking the Commissioners to explain certain apparent discrepancies between the Commissioners' letter above and Memo. 236 I.C., and we hope to deal with this when the reply of the Commissioners is received. It is, perhaps, of importance to remember that in the Act of 1911, sect. 46, provision is made for a transfer value to be paid to approved societies by the Navy and Army Fund when men are discharged and join societies, and provision is similarly made for those who become deposit contributors, or whose state of health prevents them being accepted by any society.

LONDON.

At the meeting of the London Panel Committee on November 20th the regulations for medical attendance on discharged disabled sailors and soldiers were considered. A special meeting of the Committee, held the previous week, had adjourned the consideration of the matter in view of the fact that a deputation from the Committee was to be received by the Commissioners. The impression of the deputation, as given by the chairman, Dr. Cardale, was that the Commissioners took up the attitude that Article 16 of the general regulations did not apply in this instance, but was only intended to meet any special points affecting a local area. With regard to the general circumstances attending the introduction of the regulations, the Commissioners stated that they had not made and had no intention of making regulations to be immediately operative without having first satisfied themselves that the changes were not only acquiesced in but, so far as they could judge, were desired by panel practitioners generally. In this instance they admitted no illegality whatever. There was no statutory obligation on the part of the Commissioners to consult Panel Committees, but the Commissioners made it clear that they did recognize a moral obligation to consult the profession fully, and insisted that that moral obligation had been fulfilled in this instance. In view of this ruling of the Commissioners it was decided to send a circular to the practitioners placing the circumstances fully before them, and advising them to accept the new regulations. A proposal that counsel's opinion should be sought on the rights and powers of the Panel Committee under the Acts and regulations in order to make the position of the Committee clear, was opposed by Dr. H. B. Brackenbury, who, while agreeing that every opportunity should be taken to enlarge the rights and powers of Panel Committees, protested against the spending of perhaps £50 in eliciting counsel's opinion on the particular point at issue. He was supported by a number of members, one of whom, Dr. J. V. C. Denning, said that the contention of the Committee had been proved to be wrong on three points—namely, that the Commissioners were bound to consult with the Panel Committee before making any changes in the regulations, that the six or eight weeks' notice was a matter of right, and that the Commissioners had not the power to substitute a dividend for a capitation scheme of payment. Dr. Lauriston Shaw thought it desirable to take counsel's opinion as to whether Panel Committees had a right to be consulted, and, if they had not such right, as to the manner in which they should endeavour to secure it. The recommendation that counsel's opinion be sought, was, by a majority, agreed to.

THE DEMAND FOR AN INCREASED
CAPITATION FEE.

MEETINGS IN MANCHESTER AND SALFORD.

On November 16th a crowded meeting of panel practitioners was held at the Grosvenor Hotel, Manchester, to consider the position in reference to the demand for an increase in the capitation fee for attendance on insured persons. The meeting was summoned by the Burnley Panel Committee, and the invitation was sent to the panel practitioners of Burnley, Blackburn, Bolton, Acerington, Preston, Rochdale, Oldham, Manchester, Salford, Bury, and Darwen. From the circular convening the meeting it appeared that the Burnley Panel Committee had received a letter from the Medical Secretary of the British Medical Association, dated November 9th, stating that the suggested increase had been brought to the notice of the Commissioners, and that the interview with them, the result of which is reported in the SUPPLEMENT (p. 101), was about to take place. Dr. Cox added that in all probability the result of the negotiations would require consideration by a special conference before any definite line of action was decided upon, and that the British Medical Association was not going to risk a fiasco by handing in resignations now.

The meeting was attended by several hundred panel practitioners, and Dr. T. Arthur Helme was voted to the chair. It was evident from the outset that the meeting was very much in earnest in its resolve to enforce the increase in the capitation fee. Strong remarks were made by nearly every speaker as to the dilatory methods of the Insurance Acts Committee which, it was urged, ought to have gone to the Government long before, as it was known from previous negotiations with the Commissioners on this subject that the decision did not lie with the Commissioners; and it was complained that the meeting felt that it had only two clear days in which to organize any attempt to obtain resignations from the panel. It was proposed by Dr. J. H. Taylor of Salford, and resolved, that the Panel Committees of the towns represented should be urged to summon immediately emergency meetings in their respective areas to consider the position, and to take immediate action where thought desirable, and should be asked to report to a further joint meeting of the areas to be held at an early date.

In accordance with the above resolution of the joint meeting of panel areas, an emergency meeting of the panel practitioners of Salford was held on November 18th, and, in spite of the short notice, was largely attended. The feeling appeared to be unanimous that valuable time had been lost by the Insurance Acts Committee, and that "organization forthwith of the profession," which the Conference of Panel Committees had ordered, had not been carried out; only about thirty hours now remained in which any attempt to obtain resignations from the panel could be carried out. Though such a step was forcibly advocated by several speakers, it was not considered practicable in that short time, and the meeting felt that if the demand for the increased capitation fee were not granted it could only rely on the action of the Panel Medico-Political Union to obtain it by more drastic measures. Resolutions were adopted to the effect that a substantial increase in the capitation fee is necessary, owing to the increase of values due to the war, that negotiations with this object should be continued, that the increase should date from January 1st, 1918, and that pending such negotiations practitioners should continue to act on the panel.

It was also resolved to recommend that periodical joint meetings of all the panel areas of South-East Lancashire should be held for mutual information on insurance questions and to ensure more certainly concerted action when required.

In connexion with the above report, it may be pointed out that a circular addressed to Local Medical and Panel Committees on November 19th by the Medical Secretary contains the following paragraph:

"As it appears from documents that have been sent to this office that some committees were under the impression that the collection of resignations was to take place at once in support of the claim for increased remuneration, it should be noted that the following words were deleted from a motion placed before the Conference asking for the

increase—'and that the 1918 Agreements be not signed until they (the demands previously stated) are conceded.' This was done because it was explained (1) that this was the first time a specified increase had been discussed; (2) that the Conference had no means of knowing whether insurance practitioners, to the extent of the 80 per cent. required by the collective bargaining scheme, were prepared to hand in their resignations unless the demands were conceded; and (3) that it would not be helpful to conduct negotiations on a claim which had never been specifically put before the other side if it were known that resignations were being collected. The Conference having accepted this view, no steps are being taken by the Committee at present to collect resignations, and indeed these steps cannot be taken until the Insurance Acts Committee has a definite pledge of support to the scheme from all, or at any rate a great majority, of the Local Committees throughout the country."

Meetings of Branches and Divisions.

GLASGOW AND WEST OF SCOTLAND BRANCH.

The annual general meeting of the Glasgow and West of Scotland Branch was held in the Faculty Hall, Glasgow, on November 8th, when Dr. W. F. BROWN, President, occupied the chair, and reports by the Interim Secretary and the Treasurer were approved.

Election of Officers.—The following were elected:

President: Dr. W. S. Syme. *Vice-Presidents:* Dr. W. F. Brown, Dr. D. J. Mackintosh, M.V.O., Dr. Lawrie (Greenock).

Honorary Secretary: Dr. W. Bryce (re-elected). *Interim Honorary Secretary:* Dr. J. Wishart Kerr. *Honorary Treasurer:* Dr. J. Wishart Kerr (re-elected).

Representatives: On Joint (Disablement) Committee for South-West of Scotland under the Naval and Military War Pensions Act, 1915: Dr. W. F. Brown (Ayr); on National Council for Combating Venereal Disease: Dr. T. Russell (Tollcross).

Fees.—The question of the proposed increase of medical fees was discussed, and it was agreed to send the card which had been issued to practitioners in the city to all the members of the Branch with slight alteration.

The Secretary was instructed to write to the Public Health Committee of Glasgow, pointing out that medical practitioners do not receive the full sum of one shilling as allowed by law for notifications on account of their having to prepay the postage on such notifications, and asking the Public Health Committee to authorize the issue of stamped envelopes.

Votes of Thanks.—Votes of thanks to the office-bearers, the retiring president and the chairman concluded the proceedings.

Association Notices.

ELECTION OF COUNCIL, 1917-18.

In consequence of the resignation of Major J. Livingstone London, a representative of the Glasgow and West of Scotland (five county Divisions), Border Counties, and Stirling Branches, nominations were invited to fill the vacancy.

JOHN GOFF, M.D., The Lindens, Bothwell, Lanarkshire, being the only nomination, he is hereby declared duly elected.

GUY ELLISTON,

Financial Secretary and Business Manager.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are announced by the Admiralty: Fleet Surgeons T. W. Phillips, M.B., to the Pembroke Dock Hospital and Yard; E. B. Pickthorn to the Medical Department, Admiralty; J. C. Ferguson, M.B., to Chatham Dockyard, vice Pickthorn; E. J. Finch, C.M.G., to the *Valiant*, vice Ferguson; B. F. Parish to R.N. Barracks, Chatham; C. B. Fairbank to R.N. Barracks, Devonport; J. Thornhill, M.B., to the *Hannibal*; F. J. L. P. McKenna, M.B., to the *Britannia*; W. E. Gribbell, to the *Victory*, for disposal. Staff Surgeons T. E. L. Jones to the *Glasgow*; W. C. B. Smith, H. Cooper, and R. McGiffin, M.B., to the *Tivid*, additional, for disposal. Surgeons promoted to acting Staff Surgeons: R. J. G. Parnell, J. H. B. Martin, M.B., F. L. Smith, C. D. Bell, M.B., T. C. Patterson, M.B., M. H. Langford, D.S.O., A. Fairley, M.B., A. G. V. French, A. C. Rusack, M.B., C. G. Sprague, Surgeons S. L. McBean, M.B., to the *Crescent*, additional; A. J. Tozer, to the *Powerful*. Temporary Surgeons J. F. McQueen to the *Pembroke*; T. E. Ashley to the *Tivid*; A. E. D. Bayliss to the *President*; J. B. Orr, M.D., D.S.O., M.C., and E. F. Deacon to Chatham Hospital; T. C. Clark, M.B., to the *Cumberland*, vice Thompson; F. D. Davies, W. H. Jones, A. J. Muirhead, M.B., and H. L. G. Foxall, to the *Victory*, for disposal; A. J. Pollock, M.B., and H. B. Maitland, M.B., to Haslem Hospital; W. A. McKerrrow to the *Victory* for R.N. Division; H. Rowan and A. L. Abel to the *Pembroke*, additional, for Chatham Hospital. To be temporary Surgeons: J. S. Ellis, D. McK. Black, R. Pollok, E. L. H. MacDowell.

ROYAL NAVAL VOLUNTEER RESERVE.

Staff Surgeon (acting) D. P. D. Wilkie to the *Victory*, additional, for disposal.
Surgeon Probationer R. C. Williams to the *Sourge*. To be Surgeon Probationers: W. M. Kennedy, R. G. Clouston.

ARMY MEDICAL SERVICE.

Colonel S. Hickson, C.B., M.B., to be temporary Surgeon-General.
Colonel J. W. Bullen, M.D., is retained on the active list under the provisions of Articles 120 and 522, Royal Warrant for Pay and Promotion, and to be supernumerary.
Temporary Lieut.-Colonel T. P. Legg, C.M.G., M.B., F.R.C.S., to be temporary Colonel.

ROYAL ARMY MEDICAL CORPS.

Temporary Lieut.-Colonel J. H. Brooks, M.D., relinquishes his commission on account of ill health.
To be acting Lieut.-Colonels whilst in command of a medical unit: Major R. N. Woodley, D.S.O., temporary Captain A. Jones, M.C., M.D.
Temporary Lieut.-Colonel E. H. Starling, M.D., F.R.S., relinquishes his commission.

The undermentioned are granted temporary rank whilst serving with No. 83 (Dublin) General Hospital:—As Lieut.-Colonel: H. C. Drury, M.D., F.R.C.P.I. As Majors: J. Lumsden, M.D., C. M. Benson, M.D., F.R.C.S.I., S. H. Law, M.D., F.R.C.S.I. As Captain: J. W. Killen, M.B., F.R.C.S.I.

Temporary Major Sir Vincent Nash relinquishes his commission.
Temporary Major G. D. Gray, M.D., to be acting Lieut.-Colonel whilst in command of the Chinese General Hospital.

To be temporary Lieut.-Colonels: Lieut.-Colonel R. Bruce, D.S.O., M.D., Gordon Highlanders, T.F.; temporary Major A. D. Reid.

The undermentioned are granted temporary rank whilst serving with the Staincliffe War Hospital:—As Major: J. Russell, M.D. As Captains: H. Keighley, G. S. Mill, M.D.

Temporary Major K. W. Monsarrat (Captain R.A.M.C.T.F.) relinquishes his temporary commission on reposting to T.F.

Majors relinquish the rank of temporary Lieut.-Colonel on ceasing to command a training centre: (Brevet Lieut.-Colonel) B. A. Craig, A. N. Fraser, D.S.O., M.B.

Major J. M. Cowan, M.D., R.A.M.C.(T.F.), to be temporary Lieut.-Colonel.

Major E. H. Marshall, R.F.A.(T.F.), to be temporary Major.
E. W. Hore, M.B. (Lieut.-Colonel I.M.S.reb.), to be temporary Major whilst employed with the Wharfedale War Hospital.

Temporary Captain G. Schofield, M.D., to be temporary Major.
J. W. Darling, M.C., M.B., and H. D. Welby, M.B., late temporary Captains, are granted the honorary rank of Captain.

Temporary Captains relinquish their commissions: W. J. Calder, C. Sand, J. Todd, M.D., D. R. MacGregor, M.B., S. W. Fisher, M.B., W. O. Arnold, M.B., M. W. Robertson, M.B., J. C. King, L. A. Moore, M.B., C. J. Gibson, M.D., W. B. Heywood, M.D., A. R. Wight, M.B., C. G. L. Wolf, M.D., C. W. Chaplin, M.D., T. Woodman, M.D., A. Darlow, H. M. Brown, M.B., J. T. Hurst, M.C., M.B., C. S. Kingston, R. C. Thomas, R. Kennon, M.D., J. Fleming, M.B., E. W. Alment, W. G. Lidderdale, M.B., R. Park, M.D., M. R. MacKay, M.B., J. A. Smith, M.C., M.B., W. G. T. Hepplewhite, M.C., M.D., P. J. O'Reilly, M.C., D. K. Parkes, M.B., M. P. Scanlon, M.B., F. A. Murray, J. S. Stewart, M.B., J. C. D. Simpson, M.B.

The notifications in the *London Gazette* of September 28th and October 23rd regarding temporary Captain F. C. Drew, M.B., and temporary Lieutenant G. D. Laing, M.D., respectively are cancelled.

Temporary Captain S. Samuel, M.B., relinquishes his commission on account of ill health contracted on active service.

To be temporary Captains: L. E. Williams, M.D., H. C. Martin, M.B., C. D. Pile, M.B., D. Gillespie, M.D., H. S. Moore, M.D., C. D. Keen, M.D., S. Y. Walsh, M.B., A. G. Howson, M.B., G. B. Burwell, M.C., M.B., E. M. Eaton, M.D., J. G. Greenfield, M.B., A. C. Sturdy, M.C., F.R.C.S.

To be temporary Captains for duty with the South African Native Labour Corps: T. M. Johnstone, I. M. Swanepoel.

Temporary honorary Captain H. T. Thomson, M.D., having ceased to be employed with No. 11 Stationary Hospital, relinquishes his commission.

Temporary Lieutenants to be temporary Captains: C. W. Macpherson, M.B., T. H. Martin, M.B., M. J. Wilson, M.B., H. A. Whyte-Venables, M.B., R. V. Ford, C. J. R. Hoffmeister, W. Howat, M.B., A. W. Kendall, M.B., S. F. Fouracre, M.B., W. H. Duncan, F.R.C.S.E., R. J. B. Loney, S. F. Cheesman, M. J. Loftus, D. MacKinnon, M.B., W. J. Thomas, G. A. Crowe, G. C. Hartley, M.B., A. P. Pigott, C. Duncan, M.C., M.B., T. Clapperton, M.B., J. Geoghegan, M.B., C. T. M. Ploverright, M.B., W. McAlpine, H. J. Simson, M.B., M. H. Laslett, H. Goodale, J. R. Anderson, M.B., S. H. Ryan, M.B., R. W. Nairn, M.B., S. A. Owen, M.D., T. B. Sellers, F. J. Spilsbury, D. C. P. Taylor, C. J. N. Longridge, M.D., F.R.C.S., A. L. Saunders, H. C. Burbidge, E. V. Dunkley, M.D., F. Anderson, M.B., H. Gooch, M.B., W. Turner, M.B., J. L. Lawry, M.D., E. M. Fannin, M.B., A. L. Saunders, S. Potter, T. W. G. Johnson, M.B., S. P. Bedson, M.D., A. Chance, M.D., F.R.C.S.I., K. J. Aveling, M.B., G. Adam, M.B., A. Fleming, M.B., F.R.C.S., P. J. Verrall, M.B., F.R.C.S., J. B. Anderson, M.B., J. Campbell, M.B., S. Macbeane, M.B., L. Pern, S. C. Shanks, M.B., R. Franklin, W. J. Poole, M.B., C. W. Macpherson, M.B., V. St. L. Pinnock, M.B., F. S. Poole, W. Lessey, M.D., E. A. C. Beard, M.B., R. Curle, N. Purcell, M.B., G. W. Harrison, M.C., E. R. Thompson, M.B., D. L. Carmichael, M.B., R. J. McFeeters, M.B., H. Heathcote, M.D., F. N. Marsh, M.B., J. L. Rubidge, M.B., P. A. Hall, M.B., C. L. McDonagh, M.B., H. T. Howell, E. A. Donaldson-Sim, H. R. Grellet, A. H. Porter, M.D., J. Fanstone, M.B., J. B. Ferguson, M.B., G. E. Spicer, H. E. M. Bayliss, M.B., A. S. Bradley (late Staff Surgeon R.N.), J. Glaister, M.B.

Temporary Lieutenants relinquish their commissions: W. S. Wallace, J. C. Lee, G. Elam, M.D., J. H. Stephens, M.B., W. Dunn, M.B., J. C. Nixon, M.B., R. W. S. Walker, M.D., S. Hutchinson, F. Rogerson, M.B., C. Murphy, M.B., J. C. Murray, W. J. Morrish, M.D., A. B. Ferguson, M.B., T. W. Walker, M.D., A. Spong, M.D., F.R.C.S., G. E. Macvie, M.D., G. M. B. Liddle, M.B., F.R.C.S.E., W. B. Harris, C. M. Keillor, M.D., T. G. Fenton, F.R.C.S., A. Falconer, M.B., J. Anderson, M.B., R. J. Scarr, G. Saportis, M.D., R. Govan, M.B., M. A. Harrington, M.B., R. Dunstan, F. H. P. Wills, J. L. Scott, M.B., J. McC. Gibson, M.B., W. H. Canter, M.B., C. Hackney, W. W. Dempster, S. Nix, M.D., A. I. Simey, M.D., V. F. Kroenig-Ryan, E. Lachapelle, M.B.

Temporary Lieutenant A. S. Mellor, M.B., relinquishes his commission on account of ill health.

Temporary honorary Lieutenant R. A. Holmes to be temporary Honorary Captain.

Temporary honorary Lieutenant T. J. Blackshear relinquishes his commission on account of ill health.

To be temporary honorary Lieutenants: S. R. Meaker, J. R. Beaven, M.B., J. M. Bremner, M.B., V. S. Laurin, L. W. Darrab.

To be temporary Lieutenants: W. Wright, M.B., J. M. Glasse, M.B., W. V. Naish, M.D., V. C. Pennell, W. H. Richardson, M.B., H. W. P. Young, M.D., E. A. Miller, M.B., G. M. Cameron, J. McCausland, M.B., H. M. Gilbertson, B. R. Vickers, M.B., A. S. Bradley, M.B., A. Evans, P. J. Flood, F. W. K. Lawrie, M.B., W. S. Gibson, R. V. Howell, M.B., E. W. Atkinson, G. W. Clark, M.B., C. W. S. Boggs, H. Parsons, M.B., H. Tipping, M.D., T. C. Graves, M.B., F.R.C.S., J. A. C. Smith, M.B., H. Love, W. H. Condell, N. S. Williams, H. S. Campion, M.B., J. B. McMorland, M.B., B. W. Skinner, M.D., D. McCormack, C. K. Athle, H. F. Penman, M.B., W. H. Ogilvie, M.B., G. Hoffmann, M.B.

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Lieutenants to be Captains: G. K. E. Inman, M.B., J. K. R. Landells, M.B., G. H. Rosedale, M.B., A. G. Anderson, M.B., E. Chapelle, M.B., F. J. C. Johnstone, M.B., J. Ratcliffe, M.B., J. Fellar, M.B., N. B. B. Fleming, M.B., H. D. Brown, M.B., W. M. Cameron, M.B., J. Crerar, M.B., W. Donald, M.B., G. M. Hetherington, M.B., A. R. Hill, M.B., T. J. Honeyman, M.B., J. N. Jamieson, M.B., S. Johnstone, M.B., H. E. McColl, M.B., D. B. Robertson, M.B., J. Steel, M.B., H. W. Torrance, M.B., R. N. Walker, M.B., J. E. Bannen, M.B., J. Beveridge, M.B., A. La B. Clark, M.B., R. Cunningham, M.B., J. MacA. Mackintosh, M.B., J. Stirling, M.B.
J. F. van der Westhuyzen, late Captain, is granted the honorary rank of Captain.

To be Lieutenants: Temporary honorary Lieutenant E. S. Phillips from R.A.M.C., W. D. Mackinnon, M.B., from Edinburgh University O.T.C., W. L. Yell, M.B., from Aberdeen University Contingent O.T.C., J. P. White, M.B., J. Macleod, M.B., and A. Riddell, M.B., from Glasgow University Contingent O.T.C., C. S. Baxter and W. Stansfield from Manchester University Contingent O.T.C., E. J. Coombe, J. Berry, R. F. C. H. Buchanan, J. B. D. Galbraith, M.B., I. M. Robertson, M.B., T. R. Wilson.

OVERSEAS CONTINGENTS.

CANADIAN ARMY MEDICAL SERVICE.

Assistant Directors of Medical Services: Temporary Major J. S. Jenkins, D.S.O., and to be temporary Lieut.-Colonel whilst so employed. Temporary Lieut.-Colonel C. E. Doherty relinquishes his appointment.
Deputy Assistant Director of Medical Services: Temporary Major A. Macphail.

CANADIAN ARMY MEDICAL CORPS.

Assistant Director of Medical Services:—Temporary Lieut.-Colonel H. M. Robertson relinquishes his appointment.
Temporary Major R. E. Wodehouse to be temporary Lieutenant-Colonel.

Temporary Major D. A. Whitton to be acting Lieut.-Colonel while specially employed.

Temporary Captains resign their commissions: J. F. McCracken, C. W. Anderson.

Temporary Captain G. H. Emery, from Western Ontario Regiment, to be temporary Quartermaster, with the honorary rank of Captain.

Temporary Lieutenant A. V. Greaves to be temporary Captain.

SOUTH AFRICAN MEDICAL CORPS.

Temporary Major A. Liebaert, M.D., and Captain H. J. Brady, from South African General List, to be temporary Major and temporary Captain respectively.

To be temporary Captains: A. H. Gifford, A. L. Gwiney, A. H. Lawrence.

G. Bidwell to be temporary Second Lieutenant.

BRITISH WEST INDIES REGIMENT.

I. McDowall, M.B., to be Surgeon Lieutenant.

TERRITORIAL FORCE.

ARMY MEDICAL SERVICE.

Colonel W. Kinnear, M.D., K.H.P., relinquishes his commission on account of ill health, and is granted permission to retain his rank and to wear the prescribed uniform.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel A. W. Mackintosh, M.D., Major L. B. Rawling, and Captains K. W. Monsarrat, M.B., J. S. A. Thomas, M. H. Way, W. E. Alderson, G. S. Haynes, and F. E. Price, F.R.C.S., are restored to the establishment.

Officers seconded for duty with a general hospital: Lieut.-Colonel (Brevet Colonel) A. B. Gemmell, Majors R. A. Bickersteth, M.B., F.R.C.S., M.D., T. M. Allison, E. N. Cunliffe, M.D., Captains R. W. McKenna, M.D., P. R. Wrigley, W. J. S. Bythell, W. A. Hooton, H. H. Rayner, J. B. F. Wilson, J. Stokes.

Lieut.-Colonel C. Averill, M.D., from Assistant Director of Medical Services, to be Lieut.-Colonel.

Major (temporary Lieut.-Colonel) J. G. Andrew, M.B., relinquishes his temporary rank on alteration in posting, and is restored to the establishment.

Captain A. B. Whitton, M.B., to be Major, March 23rd, 1916 (substituted for announcement in the *London Gazette* of May 27th, 1916).

Major A. Wilson, F.R.C.S., vacates his appointment on the permanent personnel, and is restored to the list of officers available for service on mobilization.

Major A. S. F. Leyton, M.D., relinquishes his commission on account of ill health.

Lieut.-Colonel E. J. R. Evatt to be temporary Colonel whilst holding the appointment of Assistant Director of Medical Services of a Division and to remain seconded.

Major (temporary Lieut.-Colonel) R. M. West, M.D., relinquishes his temporary rank on alteration in posting.

Major A. C. Hartley, M.D., relinquishes his commission on account of ill health and is granted permission to retain his rank and to wear the prescribed uniform.

Major (temporary Lieut.-Colonel) F. W. Burton-Fanning relinquishes his temporary rank and is restored to the establishment.

Major C. G. Strachan from field ambulance to be Captain.

Captain (temporary Major) R. M. Wilson relinquishes his temporary rank on alteration in posting.

Captain A. Don to be temporary Major whilst specially employed.

Captain S. W. Plummer, M.D., to be Major, August 10th, 1914 (substituted for announcement in the *London Gazette* of August 7th, 1915).

Captain H. W. Beedman, M.C., to relinquish his commission on account of ill health.

Captain R. Gill resigns his commission.

Captain (acting Lieut.-Colonel) G. S. Williamson relinquishes his acting rank on ceasing to command a field ambulance.
 Captain (acting Lieut.-Colonel) A. A. Hingston, M.B., to revert to temporary Major with precedence as from November 10th, 1914, on ceasing to command a field ambulance.
 Captain C. L. Lander, M.B., to be acting Lieut.-Colonel whilst commanding a field ambulance.
 Captain R. A. Broderick, M.C., M.B., to be acting Lieut.-Colonel whilst commanding a field ambulance.
 Captains (temporary Majors) D. H. de Souza and J. Eason, M.D., relinquish their temporary rank on alteration in posting, and are restored to the establishment.
 Captain H. F. Wilkin, M.C., F.R.C.S., from A.M.S., to be Captain.
 Captain W. B. Secretan, M.B., F.R.C.S., is seconded for duty with a war hospital.
 Captain S. Acheson, M.B., relinquishes his commission on account of ill health contracted on active service, and is granted the honorary rank of Captain.
 The seconding of Captain T. C. Holland, announced in the *London Gazette* of June 25th, 1917, is cancelled.

TERRITORIAL FORCE RESERVE.

Lieut.-Colonel S. A. M. Copeman, M.D., from R.A.M.C., to be Lieut.-Colonel.
 Majors C. S. de Segundo, M.D., and B. Addenbrook, M.D., from R.A.M.C., to be Majors.
 Captain L. C. V. Hardwicke, M.B., from field ambulance, to be Captain.
 Captain E. B. C. Mayrs, M.B., relinquishes his commission on account of ill health, and is granted the honorary rank of Captain.
 Captain (temporary Major) W. Tyson, M.D., and Captains A. G. Williams, A. Heath, M.D., F.R.C.S., W. J. Lacy-Hickey, M.B., T. Porter, M.B., J. A. Innes, M.B., W. Rogers, M.D., M. B. Dawson, and C. C. Messiter, from R.A.M.C., to be Captains.
 Captain R. G. Wills, M.B., relinquishes his commission on account of ill health.

VOLUNTEER FORCE.

Lincolnshire Medical Volunteer Corps.—Major H. P. Berry (R.A.M.C.T.F. Reserve) to be temporary Major.
County of Durham Medical Volunteer Corps.—Major T. E. Hill (late R.A.M.C.) to be temporary Lieut.-Colonel.
East Yorks Medical Volunteer Corps.—R. T. Forster (late Captain R.A.M.C.), D. H. Davy, and A. H. Field to be temporary Captains.
Lancashire Medical Volunteer Corps.—S. J. Yeates (late Lieutenant R.A.M.C.) to be temporary Captain.
Anglesey Regiment.—G. L. Jones (late Lieutenant R.A.M.C.) to be temporary Captain and Medical Officer.
Berkshire Regiment: 1st Battalion.—J. T. R. Millier to be temporary Lieutenant and Medical Officer.
Carmarthen Regiment: 1st Battalion.—Surgeon-Lieut.-Colonel E. Evans (late Welsh Regiment) to be temporary Captain and Medical Officer.
Durham Regiment: 1st Battalion.—J. C. French (late Surgeon-Lieutenant 2nd Durham R.G.A. Vols.) to be temporary Captain and Medical Officer.
Lancashire Regiment.—J. Brown to be temporary Lieutenant and Medical Officer.

Vacancies and Appointments.

VACANCIES.

NOTICES REGARDING APPOINTMENTS.—Attention is called to a Notice (see Index to Advertisements—Important Notice re Appointments) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

BOURNEMOUTH: ROYAL VICTORIA AND WEST HANTS HOSPITAL.—House-Surgeon. Salary, £175 per annum.
BRADFORD CITY.—Temporary Assistant School Medical Officer. Salary, £8 8s. per week.
BRISTOL ROYAL INFIRMARY.—(1) House-Physician. (2) House-Surgeon. Salary, £120 per annum.
DERBY: DERBYSHIRE ROYAL INFIRMARY.—House-Surgeon. Salary, £200 per annum.
HAMPSTEAD GENERAL HOSPITAL, Haverstock Hill, N.W.—Resident House-Physician. Salary, £200 per annum.
ILFORD URBAN DISTRICT COUNCIL.—Temporary Medical Officer of Health. Salary at the rate of £550 per annum.
KENSINGTON DISPENSARY AND CHILDREN'S HOSPITAL.—Resident Medical Officer.
LEICESTER CORPORATION.—Second Resident Medical Officer for the Isolation Hospital and Sanatorium. Salary, £300 per annum.
NEW HOSPITAL FOR WOMEN, Euston Road, N.W.—(1) House-Physician. (2) Obstetric Assistant. (3) Two House-Surgeons. (4) Resident Medical Officer at House of Recovery, New Barnet. (5) Clinical Assistants and Anaesthetists. Salary for (1), (2), and (3), £50 per annum, and for (4) £60 per annum.
NOTTINGHAM CHILDREN'S HOSPITAL.—Resident Lady House-Physician and Anaesthetist. Salary, £250 per annum.
QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.—House-Surgeon. Salary, £100 per annum.
RECUPERATIVE HOSTELS FOR SAILORS AND SOLDIERS INVALIDED WITH NERVE STRAIN, Fitzjohn's Avenue, N.W.—(1) Honorary Neurologist. (2) Honorary Laryngologist. (3) Resident Medical Officer; salary, £400 per annum.
STOKE-ON-TRENT BOROUGH.—Resident Assistant Medical Officer at the Stanfield Tuberculosis Sanatorium. Salary, £250 per annum.
SUNDERLAND: CHILDREN'S HOSPITAL IN CONNEXION WITH ROYAL INFIRMARY.—Resident Medical Officer. Salary, £200 per annum.
WYRE COUNTY COUNCIL.—Tuberculosis Medical Officer. Salary, £500 per annum.

WARWICK: WARWICKSHIRE COUNTY COUNCIL.—Assistant County Medical Officer of Health. Salary, £325.

CERTIFYING FACTORY SURGEON.—The Chief Inspector of Factories announces the following vacant appointment: Coventry (Warwick).

To ensure notice in this column—which is compiled from our advertisement columns, where full particulars will be found—it is necessary that advertisements should be received not later than the first post on Wednesday morning. Persons interested should refer also to the Index to Advertisements which follows the Table of Contents in the JOURNAL.

APPOINTMENTS.

BARBOT, D., M.B., Ch.B., Certifying Factory Surgeon for the Muirkirk District, co. Ayr.
COMBINS, William Edward Ashley, M.D., M.Ch., Medical Referee under the Workmen's Compensation Act, 1906, for the West Riding of the county of York (Macroom and Bandon Divisions), and for the portion of the East Riding of the county, including Cork City and Cork East Riding, except the towns of Passage Monkstown and Queenstown.
FITTON, H., L.R.C.P. Edin., M.R.C.S. Eng., Medical Officer of the Staincliffe Institution of the Dewsbury Union.
KING, J. C., M.R.C.S., L.R.C.P. Lond., Certifying Factory Surgeon for the Barry District, co. Glamorgan.
LEAKEY, C. M., L.M.S.S.A., Certifying Factory Surgeon for the Gunnislake District, co. Cornwall.
LEAKEY, Llewellyn James, B.A. Lond., M.D., Medical Superintendent of the Bristol Medical Mission, vice Dr. William Elder, deceased.
LUTHER, E. L., M.D. Dub., District Medical Officer of the Cerne Union.
MACARTHUR, John Hardie, M.B., Ch.M. Glasg., Medical Superintendent, Dunwich Benevolent Asylum, and Superintendent, Inebriate Institution, Dunwich, vice Linford Elsie Row, L.R.C.P. and S. Glasg., M.D. Brux., resigned.
ROBERTS, A. H., L.R.C.P. Lond., M.R.C.S. Eng., District and Workhouse Medical Officer of the Malling Union.
SCHOOLBREAD, Thos. B., M.B., C.M. Edin., Resident Medical Officer to the Carlisle Dispensary.
WILSON, A. R., M.D. Oxon., District Medical Officer of the Blandford Union.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTHS.

HANCOCK.—On the 15th November, at Bentley, Hants, the wife of Dr. F. Thompson Hancock, of a son.
PEARCE.—To Margaret Florence, wife of Francis Henry Pearce, Kingsland, Cumnor Hill, Oxford, a daughter (Margaret Adeline Worth), at Ridgebourne, Shrewsbury, the residence of her mother.

DEATH.

BARNARD.—On November 14th, at Boston, Lines, of acute pneumonia, Annie Thompson Barnard, M.D., B.S. Lond., D.P.H. Camb., youngest daughter of the late William Barnard, of Harlow, Essex.

DIARY FOR THE WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1.—8.30 p.m., Adjourned discussion on the Value and Limitations of Sanatorium Treatment for Tuberculosis, to be continued by Sir William Osler, Dr. A. Niven Robertson, Dr. Grace Calvert, Dr. Camac Wilkinson, Dr. Muthu, Dr. Henry Ellis, Dr. Jane Walker, Dr. John Sorley, Dr. H. J. Cardale, and others.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—5 p.m., Professor A. Keith:—Principles of Orthopaedic Treatment: Monday, Principles and Practice of John Hilton; Wednesday, Principles and Practice of Hugh Owen Thomas; Friday, Methods applied by G. F. Stromeyer, W. Adams, and J. Wolff.

ROYAL SOCIETY OF MEDICINE.—Section of Medicine: Tuesday, 5.30 p.m., Serum Disease following Intrathecal Injections. Section of Epidemiology and State Medicine: Thursday, 5 p.m., Surgeon-Colonel V. Soubbotitch (Serbian Army): Typhus Fever in Serbia, 1914-15.

POST-GRADUATE COURSES AND LECTURES.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammer-Smith, W.

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WINTER SESSION, 1917.

Tuesday, November 27th, 1917.

Sir DONALD MACALISTER, K.C.B., President,
in the Chair.

THE one hundred and sixth session of the General Council of Medical Education and Registration was opened at the offices of the Council, 44, Hallam Street, W., on Tuesday afternoon, November 27th, 1917.

PRESIDENT'S ADDRESS.

Gentlemen,—Happily I have to record but few changes in the membership of the Council since our last meeting. Dr. Robert Saundby, the representative of Birmingham University for the last twelve years, has retired, leaving a record of manful service of which he may well be proud, and for which we shall long be grateful. In all that concerned the work of the Council as a judicial body, his wide experience in the field of ethics, his well-balanced judgement, and his high sense of professional honour, gave his conclusions a great weight of authority. He is succeeded by the Vice-Chancellor of the University, Lieut. Colonel H. Gilbert Barling, C.B., whose eminence as a surgeon and an administrator ensures him a welcome among us.

Dr. George Wilks has also retired, on the ground of advancing age, after a membership of five years. We shall retain a pleasant remembrance of his courtesy and loyalty. The Society of Apothecaries of London has sent in his place Mr. Meredith Townsend, Medical Officer in the south district of Kensington. His official and personal knowledge of metropolitan conditions will be of assistance to the Council. You will learn with regret of the sudden death of our former colleague, Sir David C. McVail, who retired five years ago after twenty years' service as Crown member for Scotland. None who served with him will easily forget his forceful and independent spirit; and all will join with me in offering to his brother, Dr. John McVail, the present Crown member, our sympathy in the loss he has sustained.

His Majesty has been pleased to confer a baronetcy of the United Kingdom upon our Junior Treasurer, Sir Frederick Taylor, President of the Royal College of Physicians of London; and to admit to the Companionship of the Order of St. Michael and St. George Colonel David Hepburn, who represents in this Council the University of Wales. The Council itself is honoured by the distinctions thus bestowed on its members.

Direct Representatives.

By an Order of the Privy Council, dated August 10th, 1917, the tenure of office of the six Direct Representatives of the registered practitioners of the United Kingdom has once more been extended for a year. It would be a gratuitous error to predict what may happen at the end

of that time; but in view of the fact that a new Parliament is likely to be elected during 1918, it is possible that a general election of members to serve on this Council may fall to be held next November. In the meantime we can but carry on, with hope and courage, the duties entrusted to us, thankful that we retain for the time being the ungrudging services of our directly-elected colleagues.

The Ministry of National Service.

The conditions created by the war are pressing upon all departments of medical organization, straining to its limit the old machinery, and compelling the construction of new and extemporary devices. As you are no doubt aware, the medical duties of the Army Recruiting Department have been transferred to the civilian Ministry of National Service. The new Minister, Sir Auckland Campbell Geddes, is himself a registered medical practitioner, and he is assisted by a Medical Advisory Board, which includes members of this Council. The Ministry co-operates also with the statutory Professional Committees in England and Scotland, and through them with the Local Medical War Committees throughout the country. The new organization is designed to meet the national need of the time for the better distribution of medical services as between the army and navy and the civilian population, for the medical examination and classification of recruits for the various forms of national service, and for the conservation of our resources in the matter of candidates for medical qualifications. Many of the measures initiated by the Ministry are already in operation, and seem well calculated to produce satisfactory results in practice. It is our simple duty as a profession to support loyally the efforts of a Minister who brings to his responsible task full knowledge of the conditions and a keenly sympathetic intelligence.

Return of Medical Students from Combatant Service.

In several of my addresses since the war began, I have expressed the conviction that the withdrawal of students from the medical schools, for combatant service, would deprive the country of the necessary quota of new practitioners in the years 1918 and 1919. I have continued to press this conviction on the authorities, and have been enabled to support my view by the aid of statistics continuously furnished for the information of your Emergency Committee and of the Government by the deans of medical faculties and schools. You will remember that, in January, 1917, a census of students actually engaged in professional study showed that in the third year of the curriculum we could count only on 572 men and 261 women to provide in 1919 for the necessary accession of new practitioners to the Register. In normal times this accession should number about 1,100. Only by returning third year students then on active service could the deficiency be made good. In September the Army Council, by an instruction, subsequently amended in one point directed that students registered prior to August 1st, 1914, who had before enlistment completed two years of the curriculum, should be passed out of combatant service to resume medical study and proceed to qualification.

The Number of Students at Various Stages.

In order to determine the effect of this instruction, and to provide data for further action if necessary, the Minister of National Service requested that a fresh census of medical students in actual attendance during October, 1917, should be taken. The forms sent out by the Registrar were returnable on November 14th, and nearly all have now been received. So far as they go they show the following aggregate results, as compared with that of January, 1917:

	1917.	Men.	Women.	Total.
First year students	(Jan.	1,499	674	2,123
	Oct.	1,386	764	2,150
Second year students	(Jan.	987	472	1,459
	Oct.	871	642	1,513
Third year students	(Jan.	572	261	833
	Oct.	805	432	1,237
Fourth year students	(Jan.	851	164	1,015
	Oct.	709	194	903
Final year students	(Jan.	1,088	164	1,252
	Oct.	995	200	1,195

Of the men students of the first and second years over 520 were under 18 years of age in October, 1917, and about 180 are from places outside the United Kingdom. The third year men students (who last year numbered some 520) have increased by about 230, and the women students by about 220. The fourth year men numbered 709 and the women 194. Unless therefore all students of this standing are returned from service with the navy or the army, the supply of new men, duly qualified for the medical service of the country, cannot be maintained in 1919.

In the meantime the Minister has declared his intention to provide, if possible, that the supply of students in training shall be maintained at a level sufficient to ensure the annual accession of at least 1,000 new medical practitioners to the *Register*. To effect this purpose it will almost certainly be necessary to extend the scope of the Army Council's Instruction of September, either by relaxing its restriction to students registered prior to August 1st, 1914, or by including second year students who on enlistment were sufficiently advanced in their studies to compass the second professional examination within a few months.

Surgeon Probationers, R.N.

On the other hand, the Admiralty makes an urgent demand for capable third year students who have passed the professional examination in anatomy and physiology, and are able to render aid as surgeon probationers in the minor units of the navy. To withhold these from their studies for an indefinite period of service would unduly postpone the date of their full qualification as practitioners, and would proportionately diminish the number annually added to the *Register*. The Medical Director-General of the Navy has accordingly arranged with the Ministry of National Service that the period of service of surgeon probationers shall not be longer than six months at home or twelve months abroad. The functions of a surgeon probationer being comparable with those of a surgical dresser or student assistant in surgical wards, licensing bodies generally have agreed to accept his surgical service afloat as equivalent to six months of the hospital attendance prescribed for the minimum curriculum. The Admiralty arrangement should therefore ensure that most of the surgeon probationers will return and qualify within the normal period, and in the meanwhile they will have gained experience relevant to their profession, which may hereafter stand to their advantage as practitioners.

The Army and the Civilian Profession.

The claims of the army for fresh drafts from the civilian members of the medical profession continue, though it has become a serious problem how the claims are to be met. A War Office Committee, which included members of the Medical Council, visited the Western front during the summer for the purpose of discovering what economies in personnel, if any, might be made in the medical corps. Its report is not yet issued; but it is questionable whether any practicable economy can be commensurate with the continuous wastage due to the incidents of warfare. The devotion and success of the medical corps in preserving and restoring the health of our troops have been recognized in the warmest terms by the highest authorities; but the service is rendered at a heavy cost in sacrifice. The

Registrar informs me that on almost every page of the *Medical Register* he has had some military distinction to insert. But too often, after making the insertion, he has had to remove the bearer's name as having "died on service." In the three years 1911-13, the average number of names annually removed from the *Register* "on evidence of death" was 620. In the year 1916 the number rose to 983. In the current year it will probably not be less.

Officers of the American Medical Service.

The welcome co-operation of the United States of America in sending over medical units in advance of its troops, has afforded the Allies some relief in this respect. Officers of the American Medical Service have accepted honorary or other temporary positions in hospitals at home and abroad, and have thus released British officers and practitioners for other work. But we shall not be able to count on this help after the arrival in Europe of the American forces in full strength. And again we cannot count on American civilian practitioners to furnish many accessions to our *Register*. In the absence of American Federal legislation authorizing professional reciprocity between the United States and Britain, His Majesty in Council is debarred from applying the Medical Act, 1886, to the United States, and this Council has accordingly no power to admit American medical practitioners to the *Register*, unless they pass a recognized examination in medicine, surgery, and midwifery, and so acquire a professional title registrable in this country. Where such legislation, within or without the Empire, has been accomplished, the Council has not failed to give it effect. Already the Foreign and Colonial Lists of the *Register* include over 1,000 practitioners, and their legal status in regard to practice is the same as our own.

Dentists and Military Service.

I mentioned in May that at the request of the Director-General of National Service, Mr. Tomes and I had attended a conference on questions relating to the supply and distribution of qualified dentists for military and civil purposes. The recruiting authorities had apparently adopted no general principle regulating the calls on the dental profession for combatant service, and in some quarters the dental needs of the community had not been sufficiently regarded. Certain conclusions on the subject were adopted and laid before the Government. Since that time the question has been pressed on the authorities by the British Dental Association, and by myself on behalf of the Council. Probably as a result of our communications, a recognized professional board, called the Dental Service Committee, with a subcommittee for Scotland, has now been set up. It will advise the central and local tribunals in respect of the exemption of dentists, and will otherwise assist the authorities on the questions of supply and distribution.

Unqualified Practitioners.

Certain recent trials have shown that the present shortage of medical men has induced unqualified and unregistered persons falsely to assume professional titles, or to personate duly qualified practitioners whose names are on the *Register*. In some cases the impostor has succeeded in holding a military or other official appointment, until much mischief has been done and his fraud has been discovered. There is reason to think that other cases of false assumption or personation remain, which call for criminal investigation and prosecution by the police authorities, under the Perjury Act or other statute. The Medical Defence Union has done good service by bringing offences of the kind to public notice. The Registrar of the Council is always ready to assist in cases of doubt by examining or verifying the claims of persons professing to be registered. Grave mistakes would often be avoided, both by officials and by the public, if reference to the Registrar's office became the general practice in all such cases.

Venereal Diseases.

The Venereal Diseases Act, 1917, has passed into law since last May and is now operative in some forty English county and borough areas. Within such areas it is a penal offence for an unqualified person to treat, advise, or prescribe for patients in relation to venereal disease, or to issue public advertisements or announcements of his practice. It is to be hoped that the Act will speedily come into force throughout the whole country, so that the

destroying plague may be stayed, and its victims may be protected against the noxious cupidity of charlatans. The reforms in regard to other quack advertisements, proposed in the Criminal Law Amendment Bill, 1917, have not yet been effected by Parliament.

Midwives (Ireland) Bill.

The public advantages, in respect of maternal and infant welfare, which have followed on the operation of the Midwives Acts for England and for Scotland, respectively, have led the Government to propose a similar measure for Ireland. The Midwives (Ireland) Bill, which is now before Parliament, follows the lines of the Scottish Act and provides that the rules (*inter alia*) regulating the practice of midwives shall be communicated to the General Medical Council for its observations before they are officially approved by the Privy Council.

Committee on the Dentists Act.

The Lord President of the Privy Council has been moved to appoint a Special Committee, which includes Mr. Tomes and Sir Arthur Newsholme, to inquire into the questions raised by the Council's recent memorandum on the Dentists Act. The terms of reference are comprehensive; they are as follows:

"To investigate the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not qualified under the Dentists Act; and to consider and report upon

"1. The causes of the present inadequate supply of qualified dentists and dental surgeons;

"2. The expediency of legislation prohibiting in the United Kingdom the practice of dentistry and dental surgery by unqualified persons; and in the event of such legislation being deemed expedient, the conditions under which certain classes of unqualified persons at present engaged in the practice of dentistry might be permitted to continue in practice, by the institution of a special roll for the purpose.

"3. The practicability, without impairing the existing guarantees for the efficient practice of dentistry of (a) modifying the course of study and examination prescribed for dental qualifications; (b) reducing the time occupied; (c) diminishing the cost of training dental students."

At the request of the Committee, Sir Bertram Windle and I, with Mr. Harper, the Council's solicitor, gave evidence in support of your memorandum on November 14th. It is understood that we may be called again at a later stage. All I need say at present is that the Chairman and other members of the Committee gave a courteous and careful hearing to the Council's case, and examined us thereon in a manner which showed that they were fully seized of the important issues involved in it.

Sugar and Glycerin.

On representations from the Home Office regarding the urgent necessity of conserving the national supplies of glycerin and sugar, it became the duty of the Pharmacopoeia Committee to exercise the powers delegated to it by the Council at the last session. After careful consideration, it appeared that the Government's request for prompt action could not be met otherwise than by the immediate withdrawal of the official directions for the preparation of certain pharmacopoeial compounds, containing appreciable amounts of glycerin or sugar. Time was not allowed to the Committee to devise officially sanctioned alternatives. Practitioners had thus to be left free to prescribe, instead of the medicines hitherto official, any substitutes they might deem therapeutically equivalent, and pharmacists to apply their professional skill in suggesting suitable vehicles and adjuvants for compounding these. The proper notices for the alteration in this sense of the *British Pharmacopoeia* (1914) were accordingly adopted unanimously by the Committee, and published on behalf of the Council in the *Gazettes* of London, Edinburgh, and Dublin, in July, 1917. There is evidence that the steps taken had the desired effect of speedily reducing the consumption of glycerin and sugar for pharmaceutical purposes. In the interest of general uniformity in compounding preparations no longer official, the Pharmaceutical Society of Great Britain has this month issued, for the use of prescribers and dispensers, a formulary of suitable recipes for these preparations. Further experience

may suggest modifications of the formulæ; but a useful purpose is served by their publication at the present time. Meanwhile—I am asked by the Government to say this—practitioners will sensibly assist the authorities in charge of our supplies if they refrain from prescribing glycerin or sugar whenever an approved substitute is admissible for purposes of treatment.

Secondary Schools Examination Council.

In August the English Board of Education published a scheme, which has long been under consideration, for the establishment of a Secondary Schools Examination Council. It will include representatives of the English universities, and of the managers and teachers of State-aided schools throughout the country. It is designed to supervise the working of a system of leaving certificates for pupils under instruction in schools providing secondary education analogous to the system in operation in Scotland. The certificates are to be of two grades: one suitable for pupils of 16, and qualifying if obtained "with credit" for admission to universities; and another, suitable for pupils of 18 who have undergone a full secondary course. In each grade the syllabus of instruction at the school, and the school record of the pupil, will be taken into account.

When the scheme comes into effect it should practically solve the difficulties of the Council in regard to preliminary examinations, and by a method of which the Council has more than once expressed its hearty approval. At my request Dr. Norman Moore and Sir Francis Champneys have represented the Council in conference on the new arrangements with Mr. Fisher, the President of the Board of Education; and I desire to thank them in your name for their efficient service. I understand from Dr. Mackay that a report will be offered by the Education Committee on this important subject. You will probably agree that it would be proper to await the actual introduction of the new scheme before resuming our discussion of the present system of multiple preliminary examinations. The proposed leaving certificate may, and I trust it will, supersede these examinations in England altogether, and afford a single guarantee of sound general education which the Council may safely accept as qualifying for entrance on a professional course in this country.

Disciplinary Cases.

Cases calling for judicial inquiry will occupy much of your time during the present session; but I need not particularly refer to them. One case deals with alleged laxity in the granting of medical certificates. Several other instances of doubtful or irregular certification, reported by Tribunals and other like bodies, were considered by the Penal Cases Committee; but after explanations had been obtained, the authorities concerned were satisfied that evidence of culpable carelessness or bad faith was absent, and accordingly they have put forward no formal complaints for inquiry by the Council. I am requested, however, by the Government to state that some medical practitioners still lay themselves open to suspicion by the National Service Ministry owing to the looseness or irrelevance of the statements they profess to attest by their signature. Unverified assertions made by the patient himself, personal opinions as to his fitness or unfitness for unknown forms of service, vague predictions as to his health at some future time, and reflections on the competence of the official medical examiners, are not proper matter for a certificate signed by a practitioner as his testimony to facts within his professional knowledge. Yet some of the authorities under the Military and National Service Acts say that they could furnish examples of "certificates" which contained little else, and which they were accordingly obliged to disregard. If a medical certificate is to have its rightful weight as evidence of truth it should obviously not bear marks of bias or prejudice, still less of insincerity or laxity in its statements. Certificates which are not, in the words of the Council's Warning Notice, demonstrably "untrue, misleading, or improper," may yet be so faulty in form and substance as to discredit the practitioner who gives them, and in a measure the profession of which he is a member. I should be the last to suggest that the vast majority of practitioners are not fully conscious of the onerous obligations now laid upon them by the State in regard to certificates; my purpose will be served if the few who seem to have misapprehended these obligations are moved by my remarks to realize

their duty. Instructions have been issued to all officials and members of National Service Medical Boards that every certificate from a man's private medical attendant is to receive due consideration and is to be filed for preservation. If the certificate is confined to matters of ascertained fact in the patient's medical history and physical condition, it cannot but be helpful to the Boards who have to pronounce on his fitness or unfitness for particular forms of service. The practitioner furnishing the certificate will therefore best consult the general interest, under present conditions, if he holds to the position of an impartial witness, and declines that of an advocate or a judge.

Duration of Sittings.

The circumstances in which we meet, and in particular the difficulties of our printers and office staff, render it desirable that we should not extend our session beyond the present week, or sit late in the evenings. It may therefore be necessary, when committee work is completed, to arrange for sittings of the Council in the forenoon of one or two days, in order that our important work for the nation may not be unduly hurried.

REPRESENTATION OF REGISTERED DENTISTS ON THE COUNCIL.

Professor ARTHUR THOMSON moved:

That steps be taken to promote legislation to secure the election of direct representatives of registered dentists upon the General Medical Council.

He said that in making this proposal he was influenced by two considerations: first, the result of experience; and secondly, the ground of expediency. The Council had always done its utmost to carry out to the best of its knowledge not only the letter of the Dentists Act, but also its spirit. Were it not, however, for the happy circumstance which had placed a distinguished member of the dental profession on the Council (Mr. TOMES), the Council would have been in many instances working in the dark. It was possible that the Privy Council, in nominating Mr. TOMES, had in mind the necessity of appointing some one who had an intimate acquaintance with the working of the dental profession; but that was an accident, and there was no guarantee that in future any one else might be appointed with a special knowledge of dental interests. It seemed a somewhat extraordinary thing that such a profession should not have representation on the body which exercised not only primary control over it, but also directed its educational system. In the Dentists Act of 1878 it was very explicitly stated that of the examiners on the boards concerned with education one-half must be practising dentists, but no provision was made for the representation of that profession on the body to whom supreme control of its affairs was given. But that was forty years ago, and there were now 5,000 registered dental practitioners. He urged the expediency of the proposal on the grounds that practising dentists were likely to be more familiar with the difficulties which beset the practice of their profession owing to the unrestricted opposition of unregistered practitioners: that in matters relating to the minimum standard of education necessary to qualify for registration, such registered practitioners were best qualified to judge in respect both to the scope and variety of the subjects examined in, and the efficiency and experience required to practise the profession without detriment to the public; that the present state of things was at variance with the accepted principles of representation; that there was evidence that the number of registered dentists was insufficient; and that as members of a profession closely allied, they ought to do their utmost to promote the interests of the dental profession, and to acquire for it control over its own affairs.

Mr. C. S. TOMES, in seconding, welcomed the general terms of the motion, and said that there could hardly be two opinions with regard to the principle of representation. Since the resolution was put down at the last session a departmental committee had been sitting to consider, broadly speaking, the advisability of recommending to Parliament an amendment of the Dentists Act. What the nature of the amendments might be no one could tell, but he thought it undesirable that the Council should pass any resolution which stated too definitely how the representation was to be accomplished.

Sir J. W. MOORE thought it a great misfortune that the

practice or profession of dentistry was ever separated from the general practice of medicine and surgery. There was no more reason for such separation, there was even less, than for the establishment of a separate profession of ophthalmology. He indicated various objections to giving separate representation to a branch of what he would call the great profession of medicine, and also questioned the advisability of increasing the Council's numbers.

Dr. EDWARD MAGENNIS, speaking as one who had taken a very special interest in the dental profession, said that he knew that dentists felt great dissatisfaction because they were not represented on the Council.

Mr. J. W. B. HODSDON, while cordially agreeing with Professor Thomson's remarks, thought it advisable to make the resolution still more general in its terms. He moved, and Sir BERTRAM WINDLE seconded, the following amendment, which Professor THOMSON accepted, so that it became the substantive motion:

That it would be of advantage to the Council in administering the Dentists Act if provision were made for the appointment to the Council of assessors or members representing the dental profession.

Dr. J. A. MACDONALD and Sir ARTHUR NEWSHOLME said that they failed to understand the position of assessors as distinct from members; and Dr. LATIMER added that if by an assessor was meant one who sat by the side of other people and assisted their judgement, he thought that dentists had a right to ask to be represented, not by assessors but by full members of the Council.

Dr. NORMAN MOORE said that it would be very much better that any representatives of the dental profession should be persons who were already on the *Medical Register* and were practising dentistry.

Mr. HODSDON withdrew the reference to "assessors" from his motion, and with that amendment it was carried, with a few dissentients.

The PRESIDENT said that while no effect could be given to the motion without an Act of Parliament, he would, if the Council desired, communicate it to the Lord President of the Privy Council. The Council signified its desire that this should be done.

(To be continued.)

MATERNITY AND CHILD WELFARE LEGISLATION AND A MINISTRY OF HEALTH.

A LETTER in the following terms, dated November 20th, 1917, has been sent to the members of the War Cabinet by the Medical Secretary:

I am directed to place before you on behalf of the British Medical Association the expression of the opinion unanimously arrived at by the Committee which has been considering the subject of a Ministry of Health—namely, that it would be most inexpedient to grant to local authorities under the supervision of the Local Government Board (as it now is) the new powers which it has been proposed to give them in connexion with maternity and child welfare.

In making this representation it is desired to meet in advance the accusation that has been made against other bodies which have made a similar protest—namely, that they are actuated by a desire to protect certain supposed vested interests, and have little or no regard for the saving of maternal and child life which it is hoped will follow from the proposed new legislation. The Association yields to no body in its desire to forward measures designed to promote the welfare of the mothers and infants of the country. But it believes that it would be most unfortunate if important new powers, such as those mentioned above, were given only to the present local authorities, and under the aegis of the Local Government Board, instead of being directed from the first by a new central department, a Ministry of Health, which could command the services and the confidence of all local bodies concerned.

In the opinion of the Association effective action throughout the country in connexion with maternity and child welfare must involve the provision of domiciliary treatment, and such provision cannot be made by the present local health authorities without seriously affecting the position of Insurance Committees and prejudicing the question of the extension of the Insurance Act to dependants. As the local health authorities are the only bodies over whom the Local Government Board has any control for these purposes, the Association would submit that the grant to these bodies of powers in England and

Wales similar to those given to the local authorities in Scotland would prove ineffectual, because the existing machinery for domiciliary medical attendance, which is essential if the movement is to be really useful, is not under their control nor under that of the Local Government Board, but under the National Health Insurance organizations. Even the present activities of the local authorities in England and Wales in relation to maternity centres cannot, in the opinion of the Association, be efficient without reference to the position of other local bodies.

The Association greatly fears that the granting of the proposed powers to local authorities in England and Wales similar to those given to the Scottish local health authorities would give an excuse for delay in dealing at once with what is considered to be a matter of vastly greater importance, namely, the formation of a new central department, a Ministry of Health, which shall take the central control of all matters relating to public health; which would, therefore, deal with the subject of maternity and child welfare throughout the country as part of a general and co-ordinated scheme, and would not be restricted locally in its operations to the agency of the local authorities over whom alone the Local Government Board has control.

The object of the Association in making these representations is to prevent if possible the launching of a plan the results of which it believes would be very disappointing, and to urge on the Government the desirability of pressing forward with a scheme which would put the health legislation and administration of the country on a sound and logical basis, affecting not only maternity and child welfare work, but every other project for dealing with the physical well-being of the community.

CONTROL OF POTASSIUM COMPOUNDS.

GENERAL LICENCE FOR PURCHASE FOR MEDICINAL PURPOSES.

The Ministry of Munitions issued an order, dated October 17th, 1917, forbidding any person to purchase or take delivery of certain potassium compounds except under a licence, and no person to sell such compounds except to the holder of a licence, subject to the provision that no licence is required by a person for the purchase and delivery of the compounds in quantities not exceeding 3 lb. in any one calendar month. The order applies to caustic potash (KOH), potassium chloride (KCl), potassium carbonate (K_2CO_3), potassium sulphate (K_2SO_4), or to any material containing more than 10 per cent. of any one or more of these compounds.

The Controller of Potash Production announces that until further notice he licenses the purchase by any person of potassium compounds coming within the terms of the order, notwithstanding that such purchases may exceed an aggregate of 3 lb. per month, *provided that the compounds so purchased are used solely in B.P. form or in B.P. preparations for purely medicinal purposes.*

By this general licence retail druggists, hospitals and similar institutions, medical men, and others are relieved of the onus of applying for individual licences to purchase compounds coming within the conditions indicated in italics above, and wholesale druggists and others may supply such compounds for use as above set out without the necessity of verifying that the purchaser holds an individual licence to purchase or take delivery.

It will, however, be necessary for the wholesaler in making his returns to the Controller to state the aggregate amount and value of his sales of compounds for purely medicinal purposes during the period covered by each return. Special forms of return will be provided for this purpose.

All sales of compounds other than those exceeding 3 lb. aggregate per month per person, and the sales for medicinal purposes hereby licensed, must be conducted strictly under purchasers' licences as prescribed by the Order, and, together with an aggregate statement of sales under 3 lb., and for medicinal purposes, must be brought out on the returns as at present.

INSURANCE.

LOCAL MEDICAL AND PANEL COMMITTEES.

Surrey.—At a meeting of the Surrey Panel Committee on November 16th the following resolution was adopted

on the motion of Dr. DANIELL (Epsom), seconded by Dr. SULLY (Claygate):

That the Surrey Panel Committee adheres to the policy adopted by the Conference of Panel Committees by large majorities, and deprecates action by any other body which is in direct conflict with the policy laid down at that Conference.

THE DEMAND FOR AN INCREASED CAPITATION FEE.

The following communication has been sent to the British Medical Association by the National Health Insurance Joint Committee:

Sir,

I am directed to state that Sir Edwin Cornwall has under consideration certain resolutions of the recent Conference of Local Medical and Panel Committees, submitted by the deputation from the Insurance Acts Committee which interviewed the Commissioners on Thursday, 15th inst., representing that the present capitation rate for medical services under the National Insurance Acts should be raised from 7s. to 10s.

As the result of the deputation, it is understood that this application is submitted to the Government as arising out of special war conditions, but without prejudice on either side to the consideration of remuneration as part of any general questions as to conditions of service that may come under review at a later date.

It would seem desirable, as your Committee will doubtless agree, that the oral statements made to the Commissioners should be embodied in, and, if and so far as your Committee may consider necessary, supplemented by, a written statement, which could be placed before the Government, and supported possibly by deputation if thought desirable; if this be so, Sir Edwin Cornwall would be glad to receive any such statement from your Committee as soon as possible.

I am, Sir, your obedient Servant,
(Signed) E. HACKFORTH.

November 22nd, 1917.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are announced by the Admiralty: Staff Surgeon M. Langford, D.S.O., to the *Challenger*. Surgeons P. L. Gibson, M.B., to Chatham Hospital; F. J. Burke, M.B., to the *Fivid*, additional, for disposal. Temporary Surgeons R. Silcock to the *Hecla*; W. H. de Pre to the *Pembroke*, additional, for Chatham Hospital; A. T. Woodward, M.B., to the *Fivid*, for disposal; R. Pollok to the *Fivid*, additional, for Plymouth Hospital; A. N. Wilde to the *Victory*; J. G. Dobson, M.B., E. J. G. Sargent, B. Thomas to the *Fivid*; J. W. Pratt to the *Minerva*. To be temporary Surgeons: T. J. Kelleher, P. Ward.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Probationer J. P. Docherty to the *Victory*; S. Ackroyd to be Surgeon Probationer.

ARMY MEDICAL SERVICE.

Colonel (temporary Surgeon-General) H. N. Thompson, C.M.G., D.S.O., M.B., on completion of four years in his rank is retained on the active list under the provisions of Articles 120 and 522, Royal Warrant for Pay and Promotion.

ROYAL ARMY MEDICAL CORPS.

Temporary Lieut.-Colonel W. Butler, M.B. (Brevet Lieut.-Colonel T.F.), relinquishes his temporary commission on reposting.

Major E. L. Moss, M.C., to be acting Lieut.-Colonel whilst in command of a medical unit.

Temporary Major H. D. Harrison, M.B., F.R.C.S., relinquishes his commission on ceasing to be employed at the Welsh Metropolitan War Hospital.

Temporary Captain E. R. Fethergill, M.B., to be temporary Major.

Temporary Captain H. C. T. Langdon, M.B., to be temporary Major while specially employed.

Temporary Captains relinquish their commissions and are granted the honorary rank of Captain: R. Forbes, M.B., H. A. Treadgold, M.D.

Temporary Captain H. Cross relinquishes his commission on account of ill health.

Temporary Captain T. J. Lloyd, M.B., relinquishes his commission on account of ill health contracted on active service.

Temporary Captains relinquish their commissions: S. K. Adams, M.B., J. W. B. Thorburn, M.B., J. C. Mackwood, F. P. Maitland, J. H. Parsons, M.B., F.R.C.S., R. P. N. B. Bluet, M.C., B. M. Bennett, M.B., W. McDermott, M.B., F. W. H. Hutchinson, H. W. Kendall.

M. R. Mackay, M.B., and A. E. Stevens, M.D., late temporary Captains, are granted the honorary rank of Captain.

Temporary Lieutenants to be temporary Captains: G. Lewin, M.B., D. C. Norris, K. W. D. MacRae, M.B., J. Leach, M.B., L. Leslie, M.D., A. G. Cament, M.D., W. A. Hosson, S. W. H. Stuart, M.B., R. A. Smith, M.B., W. J. Smyth, M.B., J. S. E. Selby, H. Ainscow, M.B., H. G. K. Young, B. H. Moore, M.B., B. Knowles, M.B., J. Laing, M.B., P. R. McNaught, M.B., J. Cruickshank, M.D., W. Montgomery, M.B., H. M. Gray, T. S. S. Holmes, M.B., F.R.C.S., J. A. C. Greene, M.C., J. Fryce-Davies, G. H. Morris, Lt. H. Rains, W. A. Murray, M.B., A. G. H. Lovell, M.D., F.R.C.S., H. V. Swindale, C. E. Pepper, M.B., W. J. Stephens, S. G. Keen.

To be temporary Captains: J. C. Bayden, C. H. Phillips, G. M. Shaw, M.B., J. T. Mackenzie, M.C., A. Drouin, M.D., H. M. Godfrey, M.D., A. MacD. Westwater to be temporary honorary Captain whilst serving with the Red Cross Hospital, Bellahouston.
Temporary Lieutenants relinquish their commissions: W. S. Wildman, F.R.C.S., A. J. Macvic, M.B., E. A. Bullmore, F.R.C.S.E., A. Moyse, M.D., J. Spencer-Daniell, M.B.
Temporary Lieutenant D. V. Muller relinquishes his commission on account of ill health.

The notifications in the *London Gazette* of October 29th and November 2nd, 1917, regarding Lieutenants S. G. Kean, M.D., and A. L. Saunders respectively, are cancelled.

To be temporary Lieutenants: A. G. McKenley, M.D., H. J. Starling, M.D., C. W. Joynt, L. H. Butler, M.B., F. W. H. Pilot, M.D., T. B. H. Tabuteau, M.B., B. W. H. Fergus, M.B., J. G. Millar, M.B., W. S. Stevenson, M.D., R. Butterworth, M.B., J. C. Nixon, M.B., A. G. Wright, M.B., H. J. Villiers, J. C. Fox, G. H. Cruihart, F.R.C.S.E., H. S. Metcalfe, M.D., J. A. M. Bligh, M.D., H. L. W. Woodroffe, M.D., R. Steel, M.B., B. E. Laurence.

To be temporary honorary Lieutenant: G. S. Peppers, M.D.

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel R. M. Wilson, M.B., resigns his commission on account of ill health, and is granted permission to retain his rank and wear the prescribed uniform.

Major (temporary Lieut.-Colonel) F. J. Steward, F.R.C.S., relinquishes his temporary rank, and is restored to the establishment.

Captain (temporary Major) H. W. Wilson, M.B., F.R.C.S., relinquishes his temporary rank and is restored to the establishment.

Major W. M. Sturrock, M.B., and Captain F. J. Neary, M.B., resign their commissions on account of ill health.

Captain (temporary Major) W. W. Greer, M.D., F.R.C.S., relinquishes his temporary rank on ceasing to command a field ambulance.

Captain (temporary Major) T. B. Mount, M.D., F.R.C.S., relinquishes his temporary rank and is restored to the establishment.

Captain L. P. Harris is seconded while holding an appointment as Deputy Assistant Director of Medical Services.

Captains W. H. G. Ball, F.R.C.S., and F. V. Milburn, are seconded for duty with a general hospital.

Captains W. Cotton, M.D., J. G. Emanuel, M.D., and J. Pearson, M.B., are restored to the establishment.

Attached to Units other than Medical Units.—Surgeon Major A. C. Oldham, F.R.C.S., from R.F.A., to be Major with precedence as from July 19th, 1912 (substituted for announcement in the *London Gazette* of June 7th, 1915).

TERRITORIAL FORCE RESERVE.

Major D. E. Dickson, M.B., from R.A.M.C., to be Major.

VACANCIES.

NOTICES REGARDING APPOINTMENTS.—Attention is called to a Notice (see Index to Advertisements—Important Notice re Appointments) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

BERMONDSEY MEDICAL MISSION FOR WOMEN AND CHILDREN.—Resident (female). Salary, £150 to £200 per annum.

BIRMINGHAM EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary, £300 per annum.

BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL.—Clinical Assistant in Out-patient Department.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—House-Surgeon. Salary, £200 per annum.

BRISTOL GENERAL HOSPITAL.—Casualty House-Surgeon. Salary, £175 per annum.

BRISTOL ROYAL INFIRMARY.—(1) House-Physician, (2) House-Surgeon. Salary, £120 per annum.

CHARING CROSS HOSPITAL, W.C.—Resident Medical Officer. Salary, £400 per annum.

DARLINGTON HOSPITAL.—House-Surgeon. Salary, £200 per annum.

FIFE COUNTY COUNCIL.—Assistant Tuberculosis Officer. Salary, £350 per annum.

GENERAL LYING-IN HOSPITAL, York Road, Lambeth.—Resident Medical Officer. Salary, £100 per annum.

ILFORD URBAN DISTRICT COUNCIL.—Temporary Medical Officer of Health. Salary at the rate of £550 per annum.

LEICESTER: POOR LAW INFIRMARY.—Resident Medical Officer. Salary, £300 per annum.

LONGTON HOSPITAL.—Honorary Anaesthetist.

MANCHESTER CORPORATION.—Lady Medical Officer. Salary, £400 per annum.

MANCHESTER EDUCATION COMMITTEE.—Assistant School Medical Officer (temporary). Salary, £400 per annum.

MANCHESTER ROYAL INFIRMARY.—Resident Surgical Officer at the Central Branch. Salary, £200.

NOTTINGHAM CHILDREN'S HOSPITAL.—Resident Lady House-Physician and Anaesthetist. Salary, £250 per annum.

QUEEN MARY'S HOSPITAL FOR THE EAST END.—House-Surgeon.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Milroy Lecturer.

ROYAL FREE HOSPITAL, Gray's Inn Road, W.C.—Medical and Surgical Registrars (female).

STOKE-ON-TRENT BOROUGH.—Resident Assistant Medical Officer at the Stanfield Tuberculosis Sanatorium. Salary, £250 per annum.

STOKE-ON-TRENT: NORTH STAFFORDSHIRE INFIRMARY.—House-Surgeon (lady). Salary, £200 per annum.

SUNDERLAND: CHILDREN'S HOSPITAL IN CONNEXION WITH ROYAL INFIRMARY.—Resident Medical Officer. Salary, £200 per annum.

SWANSEA GENERAL HOSPITAL.—Fourth or fifth year student to act as Assistant to House-Surgeons. Salary, £100.

WANDSWORTH UNION.—Assistant Medical Officer (temporary) at St. James's Infirmary. Salary, £7 7s. a week.

WEST LONDON HOSPITAL, Hammersmith Road, W.—Clinical Assistants.

YORK COUNTY HOSPITAL.—House-Physician (lady). Salary, £200 per annum.

To ensure notice in this column—which is compiled from our advertisement columns, where full particulars will be found—it is necessary that advertisements should be received not later than the first post on Wednesday morning. Persons interested should refer also to the Index to Advertisements which follows the Table of Contents in the JOURNAL.

APPOINTMENTS.

ANDERSON, M. C. B., M.R.C.S., L.R.C.P., District Medical Officer of the Wareham and Purbeck Union.

KING, J. C., M.R.C.S., L.R.C.P., District Medical Officer of the Cardiff Union.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTH.

PHILP.—On November 25th, at 9, Northmoor Road, Oxford, the wife (née Margaret Fussell) of Captain C. H. G. Philp, M.B., R.A.M.C., of a son.

MARRIAGES.

COCK—TINDALL.—On November 24th, at the Church of the Assumption (Royal Bavarian Chapel), Warwick Street, W., Reginald Cock, M.R.C.S., L.R.C.P., son of Henry Cock, M.V.O., late Chief Constructor to the Admiralty, and of Mrs. Cock, Stonehouse, Plymouth, to Mollie, eldest daughter of the late Captain C. S. Tindall, Royal Mail Steam Packet Company, and of Mrs. Tindall, Shoreham-by-Sea, Sussex.

OWEN—PRICE.—On November 23rd, at the Tabernacle C.M. Church, Bangor, N. Wales, Leonard V. D. Owen, Lieutenant Oxford and Bucks Light Infantry (Lecturer in History, Sheffield University), to Gwen, eldest daughter of Dr. and Mrs. E. O. Price, Bangor.

VASSIE—MCNEILL.—On November 20th, at St. John's Church, Paddington, by the Rev. J. R. Hale, M.A., C.F., Vicar of Boxley, Kent, assisted by the Rev. A. E. Oldroyd, M.A., Vicar of St. James's, West Hampstead, A. H. Vassie, M.B., of 98, Priory Road, N.W., to Margaret Lyons Grace McNeill, daughter of the late Mr. and Mrs. John McNeill.

DEATHS.

GOODSON.—On November 22nd, 1917, at "Wendover," West Road, Westcliff-on-Sea, William Goodson, L.R.C.P. (Edin.), late of Stratford, aged 79 years. Cremation City of London Cemetery.

JAMESON.—On November 26th at 2, Great Cumberland Place, W.1, Sir Leander Starr Jameson, Bt., P.C., C.B., M.D., in his 65th year. Memorial Service at St. Margaret's, Westminster, December 5th, 12.30 p.m. No flowers by special request.

DIARY FOR THE WEEK.

MONDAY.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1, 8.30 p.m.—Discussion on Surgical and Dental Treatment of Severe Facial Injuries, to be introduced by Major H. D. Gillies, R.A.M.C. Captain Kelsey Frey, R.A.M.C.(T.), and Mr. Percival Cole.

THURSDAY.

HUNTERIAN SOCIETY, 1, Wimpole Street, W., 5 p.m.—Discussion: The Medical Classification of Recruits, to be opened by Captain Haldin Davis, R.A.M.C.

FRIDAY.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, 8.30 p.m.—The Methods of Detecting Simulated—(1) Deafness, by Mr. Richard Lake—(2) Blindness, by Mr. Percy Dunn.

POST-GRADUATE COURSES AND LECTURES.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C., 5 p.m.—Professor A. Keith: Principles of Orthopaedic Treatment. Monday, Application of Discoveries made by Marshall Hall, C. E. Beevor, and Duchenne. Wednesday and Friday, Bearings of Discoveries of Modern Neurologists on Orthopaedic Practice.

ROYAL SOCIETY OF MEDICINE.—Section of Psychiatry: Tuesday, 4.30 p.m., Captain W. H. R. Rivers, R.A.M.C., F.R.S.: Repression of War Experience. Section of Pathology: Tuesday, 8.30 p.m., Dr. W. S. Lazarus-Barlow: An Attempt at the Experimental Production of Carcinoma by means of Radium; Professor S. G. Shattock, F.R.S.: Explosive Phenomena in Gunshot Wounds. Section of Bacteriology and Climatology: Thursday, 5.30 p.m., Dr. C. F. Sonntag: (1) Whirlpool and Manipulation Baths; (2) The Arthrodynamicograph. (At 7.15 p.m. the members will dine together at Paganini's Restaurant, Great Portland Street, W.) Section of Obstetrics and Gynaecology: Thursday, 8 p.m., Discussion: Scopolamine-morphine Narcosis in Childbirth, to be opened by Dr. J. S. Fairbairn, Dr. C. Hubert Roberts, Mr. T. G. Stevens, and Dr. Herbert Williamson. Section of Laryngology: Friday, 4 p.m., Cases. Section of Epidemiology and State Medicine: Friday, 8.30 p.m., Presidential Address by Lieut.-Colonel G. S. Buchanan, M.D.: Epidemics of the Eastern Campaign.

DIARY OF THE ASSOCIATION.

CURRENT NOTES.

Organization of the Profession.

The Medical Secretary took the opportunity of a visit to Lancashire on business for the Central Medical War Committee to address meetings of the profession at Blackburn, Preston, and Warrington on the organization of the profession, particularly as it affects that section of it working under the Insurance Acts. The meetings at Blackburn and Warrington were arranged by the honorary secretaries of the respective Divisions and were well attended, especially that at Blackburn, where between fifty and sixty practitioners were present. The meeting at Preston was called by the Lancashire Panel Committee. There was a very large attendance and, after Dr. Cox's address, full opportunity was given and taken for questions. The pressure on our columns prevents the publication of a report of the meeting this week, but we hope it may appear in our next issue.

Erratum.

The Medical Secretary wishes to draw attention to a mistake made at the foot of page 3 of document M.17, sent to Local Medical and Panel Committees, where certain resolutions of the October Conference are quoted upon the question of increase of remuneration. Minutes 58, 59, 60, and 61 are given, but obviously the last mentioned was quoted in error, as it is not a complete resolution, but only a motion to which words were added before it became a resolution of the Conference. The complete resolution is as follows:

Minute 61.—Resolved: That the Insurance Acts Committee be instructed to negotiate these terms with the Government, and to organize the profession forthwith in furtherance of this object.

GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION.

WINTER SESSION, 1917.

Sir DONALD MACALISTER, K.C.B., President,
in the Chair.

PUBLIC HEALTH COMMITTEE.

Experience with the Expeditionary Force and the Diploma in Public Health.

THE Public Health Committee reported that an application had been considered from a captain R.A.M.C. asking for recognition of work carried out by him in connexion with his military duties in France in lieu of certain courses of study prescribed for the D.P.H. Oxford. After Lieut. Colonel Beveridge, Assistant Director for Medical Services (Sanitation), B.E.F., France, had given information as to conditions existing in the field which would justify

temporary modification in the rules and regulations, the Committee agreed to suggest certain such modifications in the case of medical officers of the Expeditionary Force.

Sir JOHN MOORE moved, in order to make it clear that the Council was the paramount authority in regard to the curriculum and examination for the public health diplomas:

That when an application is made for exemption from some of the training laid down by the Council as the minimum necessary before entering for the examination for the diploma in public health, the decision must rest with the General Medical Council itself.

Dr. NORMAN MOORE said that the powers of the Council in this matter rested upon the Act of 1886 and a report to the Council of 1889, but he proposed to ask the Council not to accept the recommendation, purely on the ground of public convenience. If an exceptional case arose the proper course was for the licensing body to report its action in the matter to the Council. It was true that the licensing body might err in the relaxation it allowed in a particular instance, but it was not likely to go on erring for long when it had to report to the Council.

THE PRESIDENT said that if the licensing body made an exception from the rules laid down by the Council, it reported to the Council, and the Council could refuse to register the diploma in question. That machinery was quite workable.

Dr. J. C. McVAIL said that the "exemption" spoken of in the recommendation was purely nominal; it was really substitution, and it seemed reasonable that any such substitution should be uniform. If the matter were left to the different examining bodies throughout the kingdom, differences of standard might well arise; therefore requests for substitution—of which he entirely approved—should all come before the same body, and it was thought that the Council might give powers to its Public Health Committee which would be exercised by a thoroughly reliable subcommittee acting in relation with the higher authorities in every case.

Sir JOHN MOORE, by leave, withdrew the recommendation; it was understood that the Council made no pronouncement one way or another. He then submitted the proposed modifications. The first was an additional note to Rule 2 for the diploma in public health:

That the laboratory experience at a base hygiene laboratory, when and so far as approved by the General Medical Council, shall count towards the four months' laboratory course prescribed by the Council; and that laboratory experience acquired by medical officers on the staff of hospitals for infectious diseases shall count for such part of the laboratory course for the diploma in public health as the A.D.M.S. (Sanitation) may recommend, and the General Medical Council on consideration may approve.

The second consisted of the addition after Rule 3 (j) of the words "or in charge of a base district on lines of communication of a British Expeditionary Force and holding a diploma in public health or other public health qualification," together with the appropriate addition to the list of districts and commands recognized by the Council under this same rule. These modifications were agreed to, and it was further decided that they should be

communicated to the various Licensing bodies in the United Kingdom which granted diplomas in public health or other public health qualifications.

DISCIPLINARY CASES.

Supply of Drugs by Doctor to Patient who had formed the Drug Habit.

On November 28th and 29th the Council considered at great length the case of Reginald Nitch Smith, M.R.C.S., L.R.C.P., of 10, New Bond Street, W., who appeared on the charge—

That being a registered medical practitioner you abused your position:

1. By selling to Mrs. Deborah Platt at exorbitant prices, at frequent intervals, and otherwise than as a medicine in the course of your treatment of her, large quantities of a narcotic toxicant drug named heroin, and knowing that she had formed the drug habit continued so to supply her to her moral and physical detriment;

2. By selling to the said Mrs. Deborah Platt the said drug at exorbitant prices and at frequent intervals for an officer and men, members of His Majesty's Forces, contrary to Regulation 40 of the Defence of the Realm Regulations, and of the Order of the Army Council, dated May 11th, 1916.

And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainant in the case was Lieutenant Ernest John Hodder Platt, who was represented by Mr. Gill, K.C. Dr. Nitch Smith was represented by Mr. Colam, K.C., and Mr. Zeitlyn.

Mr. GILL, in opening, said that the conduct of the practitioner in this case was so extraordinary that it could only be explained on the ground that he had supposed that when dealing with a victim of the drug habit he could act with impunity. Mrs. Platt was arrested on July 6th last on a charge of stealing jewellery in Bond Street, but on being taken to the police station her condition was so obvious that the divisional surgeon was sent for and found her to be suffering from the effects of a drug. She afterwards made a statement that she had been taking very large quantities of drugs, which had been supplied to her by Dr. Nitch Smith. A large number of cheques drawn by this lady were found to have been dealt with by Dr. Nitch Smith, and it was quite clear that she was in constant communication with him from January of this year down to within a day or two of her arrest. When the case was sent for trial, the judge came to the conclusion that medical treatment rather than imprisonment was called for, and accepted sureties for her good behaviour; at the same time he said that it was a case for the General Medical Council. The lady's statement was that on returning from France at the end of last year she desired to procure the drug heroin, as French doctors had recommended her to take it; and finding that she could not obtain it in this country without a doctor's prescription, and the name of Dr. Nitch Smith having been mentioned by a chemist of whom she inquired, she went to him, and he at first gave her a prescription, and afterwards himself supplied her with the drug as required. The number of cheques parted with by the lady in Dr. Nitch Smith's favour was fifty-one, and the total amount £137 10s. Every cheque from the beginning of March was—(the lady said, at Dr. Nitch Smith's request)—made payable to bearer. On fourteen occasions the drug was sent for by district messenger, who called at Dr. Nitch Smith's house for it. The chemist with whom Dr. Nitch Smith dealt had supplied him with heroin on seventeen occasions between January and July. The counsel went through Dr. Nitch Smith's deposition, which he claimed, apart from the lady's evidence, bore out the contention of grave irregularity. It was to the effect that Mrs. Platt consulted him in the early part of the year, stating that she had been taking heroin in France. She was suffering from some degree of bronchitis and profuse expectoration. He prescribed heroin for her on two or three occasions, and then she asked him to obtain the drug directly for her, which he did. When, later on, she asked for larger quantities than the previous limited supply, she told him, on inquiry, that she was sending the excess amount to her husband, an officer in France, for his use and that of some of the men who were with him. On no occasion during the eighteen personal interviews he had had with her had he seen any harmful effects of the drug. The reason she gave for not seeing him on certain occasions when the drug was supplied was that she was working at the War Office and unable to get away. Dr. Nitch Smith

had further stated that while visiting his consulting room she became acquainted with his attendant and obtained from her on occasion other quantities of the drug without his knowledge. Mr. Gill submitted that the case was one of the gravest possible importance, and he cited the stringent regulations made under the Defence of the Realm Act.

Mrs. Platt, in evidence, stated that she remembered receiving only one prescription from Dr. Nitch Smith. She had not paid him eighteen or twenty visits as he alleged, but five at the most. She denied having arranged with Dr. Smith's attendant for the supply of drugs in the doctor's absence; on two occasions only she had implored the attendant to give her more, which she did. The doctor had never warned her against taking too much of the drug. She admitted having stated that she wanted some of the drug to send to her husband in the Flying Corps for the use of his pilots, but she had not, in fact, sent any of the drug to France. She took the drug hypodermically. She had never had bronchitis, and had never mentioned bronchitis to the doctor.

The bank cashier and the chemist spoke as to the cheques and the sales of the drugs respectively. The chemist said that he had supplied some of the drugs by telephone order from the doctor's attendant, whose voice he recognized.

Dr. Nitch Smith gave evidence, in the course of which he said that Mrs. Platt called upon him in January to consult him for chest trouble. She was then in a wheezy, bronchitic condition. He prescribed two tubes of heroin, a drug she had already been using, and he gave similar prescriptions on six or eight later occasions. Afterwards she said that she was unable to come to see him owing to war work, and asked him to obtain the drug for her. He did not know that his attendant was also letting her have some further supplies of the drug. He never received a cheque from her other than after a consultation save on three occasions, when she was not able to come, and he let her have two tubes each time. He produced his case book on Mr. Gill's demand, but it had only the record of one prescription for Mrs. Platt; he explained that the others were not recorded when they were of the same character as the first. He had never personally received a cheque from Mrs. Platt for more than £2 10s. Cheques for larger amounts—£5 or £6—were paid into his banking account without his knowledge by his attendant. Some cheques were cashed through an agency of which he knew nothing. He had been in a bad state of health for some time, and had had to rely upon his attendant for the routine of his business. He added that he had had many drug-takers under his care, and might claim to be an expert in drug effects. He had never come across a case of heroin poisoning in this country, though it was common in France and America.

Miss Hall, the attendant in Dr. Smith's employment, stated that she had been in his service for twelve years. She remembered Mrs. Platt coming perhaps eighteen or twenty times. On several occasions Mrs. Platt had begged the witness to get her a supply of heroin, which ultimately she did, keeping the cheque back for a time, until, growing nervous over the matter, she paid it in to the doctor's account. Ordinarily three tubes were given to Mrs. Platt's messenger each time she sent. She had looked up a book which stated that heroin was a cure for chest trouble. She had no idea that it was so dangerous; otherwise she would not have given it.

Mr. COLAM, in his speech for Dr. Nitch Smith, traversed Mrs. Platt's statement, and presented the case as an issue between her reliability and the doctor's. The incontestable fact was that some of these supplies of drugs were obtained by this lady without the doctor's knowledge. The doctor had never let her have more than two tubes at a time. Indiscipline there might have been, but not infamous conduct in a professional respect.

Mr. GILL replied that the case against Dr. Nitch Smith in no way depended upon Mrs. Platt's statement. The defendant's own deposition as given originally to the police, and upon which he had commented in opening, was quite sufficient. Within the period covered by the case something like 430 tubes of the drug had been supplied to Dr. Nitch Smith by the chemist, and during the month of June—the month previous to the lady's arrest—batches of four dozen tubes were supplied on three or four occasions. He submitted that the case was one of exceptional gravity.

The Council deliberated in private, and afterwards the President announced the decision of the Council as follows:

Mr. Nitch Smith, I have to inform you that the Council have come to the following conclusion:

That you have been judged to have been guilty of infamous conduct in a professional respect, and that the Acting Registrar has been directed to erase your name from the *Medical Register*.

Giving Certificates Without Personal Examination.

On November 29th the Council considered the case of Frederick William Salter, L.R.C.P., L.R.C.S., of Glarhiew, New Mills, Newtown, Montgomeryshire, who appeared in

answer to the charge of giving seven certificates bearing various dates from January to June, 1917, as to the health of a man who was liable to service under the Military Service Acts without seeing or examining him, whereby this man was enabled for a time to avoid military service, all of which certificates were untrue, misleading, or improper.

The complainant was Dr. R. W. Johnstone, Deputy Commissioner of Medical Services of National Service.

Mr. SPEAR, on behalf of the complainant, said that the man with regard to whose health the certificates were given was T. O. Davies, aged 20, living in Montgomeryshire, at a place thirty five miles distant from the residence of Dr. Salter. On December 10th last Davies was visiting some friends in the neighbourhood of New Mills, and was taken ill with some sort of rheumatic complaint, and Dr. Salter attended him for the next fortnight. On December 24th the man was well enough to return to his home. He received a calling up notice for military service about January 1st, whereupon a certificate from Dr. Salter dated December 18th was sent to the recruiting officer, who, after the receipt of it, asked for a further certificate nearer to the date for which the man was actually summoned. Although Dr. Salter never saw the man at all after December 24th, he continued to give certificates based upon written information sent him by the man. Ultimately, when it was thought advisable that the military authorities should see the man, Colonel Cureton, commanding the military hospital at Shrewsbury, called and examined him on May 22nd, and found him on that date in good health and, in his opinion, fit for service, yet, on June 2nd, there was a further certificate from Dr. Salter that Davies was not fit to travel, although the doctor had not himself seen the man for five months. It was beyond question that certificates should be given only after personal examination.

Mr. ELLIS GRIFFITH, K.C., who appeared for Dr. Salter, said that his client recognized quite frankly that he had done an imprudent thing in granting these certificates, but he contested the assertion that they were untrue. Dr. Salter held many public posts in Montgomeryshire, and was a justice of the peace for the county. In December last this young stranger, who was a ministerial student, visited the neighbourhood to preach, and was taken ill through sleeping in a damp bed. He was attended by Dr. Salter frequently during a fortnight, and as a result of the knowledge of his condition which the doctor had acquired in that time he continued to send him medicines and liniments after his return home, and also at his request to grant him certificates. On every certificate, however, he put his own address and that of the man, and to any one with local knowledge it would be obvious from the geographical facts of the case that he could not be in actual attendance on him. There was no attempt on Dr. Salter's part to keep him out of the army. A letter of his, written in the late spring, that the man would probably be able to go to Wrexham before the Medical Board in a month's time was based on the fact that by then the weather would be warmer, an important consideration in view of the man's rheumatic condition. Davies joined the army in June, but from September 8th until the present day he had been in a hospital bed, and had only done about a fortnight's military duty. This bore out the serious view of the man's condition which the doctor had formed from the beginning.

Dr. SALTER, in evidence, said that when he saw Davies the man was suffering from acute rheumatism and from valvular disease of the heart. He formed the highest opinion as to his straightforwardness and integrity, and therefore took his written statements afterwards unquestioningly. He only charged him half-a-guinea for the treatment he gave him in December, and did not charge him anything for the medicines and liniments he sent to his home. When the certificates were first asked for he had no notion of the man's liability to military service. He understood that they were required in connexion with his examination for the ministry. Later on, however, after the man had returned to his home, he knew that the further certificates were required in response to the demands of the recruiting officer. He regarded the case as one of heart disease; the man never was fit for military service. Later on he was anxious for him to go to Wrexham to be examined, to get the opinion of the army medical authorities; he believed that he would be totally rejected.

The man's medical history sheet was handed in, from which it appeared that he was classified "B1" at Wrexham on June 4th.

Mr. L. MATLEY, solicitor, brought forward a written statement which he had obtained from Davies at the Preses Heath Hospital, Shropshire, a few days previously, reciting the facts of his case. The word "myalgia" and under it the initials "D. A. H." appeared above his bed.

After the Council had deliberated in private, the President announced the decision of the Council as follows:

Mr. Salter, I have to inform you that the Council has found that certain of the facts alleged against you in the notice of inquiry—namely, that you have given certificates which were misleading or improper—have been proved. The Council takes a very grave view of the offence which you have committed, and has issued a Warning Notice in regard to the giving of medical certificates as follows:

"Registered practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give, certificates, notifications, reports, and other documents of a kindred character, signed by them in their professional capacity, for subsequent use either in courts of justice or for administrative purposes.

"Such documents include, among others, certificates, notifications, reports, etc. . . .

"(a) For excusing attendance in courts of justice, in the public services, in public offices, or in ordinary employments.

"(b) In connexion with naval and military matters.

"Any registered practitioner who shall be shown to have signed or given under his name and authority any such certificate, notification, report, or document of a kindred character, which is untrue, misleading, or improper, whether relating to the several matters above specified or otherwise, is liable to have his name erased from the Register."

In order to give you an opportunity to prove to the Council that you realize the gravity of your offence, and to produce evidence from your professional brethren regarding your character and conduct generally, the Council has postponed judgement till the May session, when you will be required to attend. Before that date you will be required to send to the Registrar of the Council the names of some of your professional brethren who may be willing upon written application from the Registrar to testify by letter, addressed to him for the use of the Council, as to your character and conduct in the interval. You will receive in due course a formal written intimation of what I have just announced to you, and the intimation will specify the dates to which I have referred.

On behalf of the Council the President tendered to Mr. Spear and to the Ministry of National Service its thanks for the assistance which they had rendered in placing the facts before it.

PHARMACOPOEIA COMMITTEE.

Use of Glycerin and Sugar in Pharmacy.

The report of the Pharmacopoeia Committee, after noting that they had, in the national interest, agreed unanimously to the temporary withdrawal from the *Pharmacopoeia* of the official directions for the use of glycerin and sugar in the compounding of certain preparations, expressed concurrence in the resolution passed at the last Representative Meeting of the British Medical Association with regard to the benefits likely to attach to a general use of the metric system in teaching.

(To be continued.)

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are reported by the Admiralty: Fleet Surgeon (retired) M. C. Langford promoted to the rank of Deputy Surgeon-General (retired). Fleet Surgeon E. T. P. Eames to the *Flood*, additional, for disposal. Surgeons H. White, to R.M.A., Eastney; R. M. R. Thursfield, to the *Boudicca*. Temporary Surgeons A. H. Moore to the *Grafton*, A. Selby-Green to Plymouth Hospital, K. R. Hill to Chatham Hospital, D. Stewart to the *Newcastle*, C. V. Samwell to Haslar Hospital. To be temporary Surgeons: R. C. W. Staley, P. J. Swanepoel, M.B., C. M. Bower.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon W. G. Evans, M.D., to the *Dryad*.

ARMY MEDICAL SERVICE.

Colonel F. R. Newland, C.M.G., M.B., to be temporary Surgeon-General.

ROYAL ARMY MEDICAL CORPS.

Major T. B. Moriarty to be acting Lieut.-Colonel whilst in command of a medical unit, July 3rd (substituted for notification in the *London Gazette* of October 2nd).

Major J. F. Whelan, M.B., to be acting Lieut.-Colonel whilst in command of a medical unit.

Temporary Major G. D. Gray, M.D., to be acting Lieut.-Colonel whilst in command of the Chinese General Hospital, May 22nd (substituted for notification in the *London Gazette* of November 12th).

Temporary Captains relinquish their commissions: N. McGowan, S. Pinion, M.B., A. J. Best, L. Cairns, M.D., J. H. O'Neill, W. R. W.

CURRENT NOTES.

The Supply of Carbide for Motor Head-lamps.

The whole of the stocks and supplies of calcium carbide in this country have for some time been required for war purposes. The position is still far from satisfactory, and the Priority Branch of the Ministry of Munitions of War can only release quite small quantities for lighting the head-lamps of motor cars or motor cycles used by medical practitioners, and only where an urgent need exists for such supply and other means of lighting are not available. The demand should at present be restricted to what will be required over a period of three months; the requisition forms are obtainable through the usual channels of supply. The Ministry of Munitions has asked the British Medical Association to undertake the investigation of all demands on the part of medical practitioners, and only to pass on to the department such demands as the Association is in a position to recommend; the Association has accepted the responsibility of advising the department in this respect. It must be understood that no carbide can be released for lighting houses, nor for lighting surgeries, and that applications in respect of motor cars and motor cycles should be restricted to cases of exceptional difficulty.

Treatment of Discharged Disabled Soldiers and Sailors.

The attention of the Insurance Acts Committee has been drawn to two instances of mistaken procedure adopted by clerks to Insurance Committees in connexion with the arrangements for the domiciliary treatment of discharged disabled soldiers and sailors, with consequent detrimental results to the practitioners concerned. All men discharged subsequent to the coming into operation of the scheme are provided with Form I.S.1. for presentation to the doctor of their choice. If the doctor accepts, he signs that form and forwards it to the clerk of the local Insurance Committee, who should issue a blue (medical) card to the discharged soldier, and notify the serial number thereof to the doctor. Payment on the attendance basis thereupon commences for any treatment given from and including that first visit. It appears, however, that, owing to names of insured persons not having been removed from a doctor's ordinary panel list on joining the army, some Insurance Committee clerks, upon receiving from a doctor Form I.S.1. regard such discharged men as already on the doctor's ordinary panel list, even though some considerable time has been spent in the army or navy, and forward to the doctor Form I.S.2 to sign and return. If Form I.S.2 is signed by the doctor he is only paid on the payment per attendance basis as from the commencement of the following quarter. No money is received by him from any source in respect of any attendance given to the insured up to the beginning of the next quarter, because even though the insured's name is on the doctor's ordinary capitation list no money goes into the Central Pool in respect of that person, since the money available therefor

has already gone into the Special Fund set up to defray the cost of treatment on the payment per attendance basis. Doctors who are applied to by discharged men for treatment and who tender Form I.S.1. should, after signing and returning that form to the Insurance Committee clerk, take care, in those instances where treatment has been given, that they receive in return from the Insurance Committee a notification of the serial number of the insured's special blue (medical) card, in order to enter that number at the head of the account which they will have already opened in respect of the patient.

THE ORGANIZATION OF THE PROFESSION.

MEETING OF LANCASHIRE PRACTITIONERS.

A MEETING which had been called by the Lancashire Panel Committee was held in the County Hall, Preston, on November 29th, when an address was delivered by Dr. ALFRED COX. The chair was taken by Dr. H. F. OLDHAM, Chairman of the Committee, and over 200 practitioners from all parts of the county were present.

THE CHAIRMAN said that when he learnt that Dr. Cox was coming to Lancashire for the purpose of interviewing certain committees he thought it would be an admirable opportunity for Lancashire practitioners to meet the Medical Secretary of the British Medical Association, and to put to Dr. Cox some of those questions which they were continually addressing to Dr. Campbell and himself. For his own part, he wished to touch only on one matter, namely, the protection of the practices of men absent on service. All those present were well aware that the duties of the Local Medical War Committees were, practically, to recruit the profession for the army. The responsibilities of those committees, however, did not cease when they had selected the men who could best be spared from a district and had recommended them for commissions. It was their further duty to safeguard in every way possible the practices of the absent men. They had failed in their duty if, having sent men into the army, they did not thoroughly and honourably defend the interests which those men had left in their keeping. In the matter of military service the medical profession had been treated on an entirely different footing from every other class in the community. The Government had regarded the profession as a guild, and had handed over to the profession itself its own recruiting. Not even the War Ministry had the right to interfere once this had been done. When Lord Derby on a certain occasion rushed a particular matter through, he had afterwards to withdraw, for no Minister of the Crown could step in between the medical profession and the rights which had been conferred upon it. To have been given such rights was a triumph, and if only the responsibilities attaching thereto were properly discharged, the effect would be to place the profession in a position it had never held previously in the social polity of the country. When the Insurance Committee ventured to intervene between the Local Medical War Committee and its work and came to the Panel Committee with the delightful suggestion that a joint committee should be set up which should carry out the

duties, he was proud to say that his own committee (Lancashire) absolutely refused to have anything to do with such a project. The duty of the Panel Committee was to see that the panel patients of a man who went into the army were properly looked after, and the duty of the Local Medical War Committee was to select the men. They would have nothing to do with any committee which attempted to interfere between the War Committee and the matters over which it was given control. Dr. Oldham went on to appeal to the individual practitioner to accept loyally the decision of the profession as expressed through the War Committee, and said that it was due to the action of the British Medical Association, and to no other influence whatever, that the profession stood apart from the rest of the community in the proud position of a guild which was privileged to have the deciding voice in its own affairs. In conclusion, he said that he had received from the secretary of the Panel Committee a circular, which had been sent out by the secretary of the Burnley Panel Committee, giving notice of a meeting to be held in Manchester to discuss certain questions relating to policy. But the questions were those which had already been discussed and decided by the Conference of Panel Committees in London on October 18th, and as a result of that conference certain action had been taken by the Insurance Acts Committee. It was a great mistake to call a meeting to discuss those very questions when the machinery was already moving to carry out the decisions of the Conference. The practitioners of Lancashire and Cheshire had elected Dr. Campbell and himself as their representatives on the Insurance Acts Committee, and in accepting that position they had considered themselves empowered to speak for the area. Yet when this meeting of medical men was called they were not summoned nor invited, nor even informed. He pleaded for loyalty to the men whom they had elected to represent them on the central body, and said that, given this, and the courage which the British Medical Association had always shown in the past in tackling these problems, a very great deal could be done, not on behalf of panel practitioners only, but on behalf of the whole profession.

Dr. ALFRED COX, after expressing his pleasure at being able to attend so large a meeting of the profession, devoted the main part of his address to the question of professional organization on democratic lines. The profession had got beyond the stage when it was prepared to be governed by a few selected superior persons who would lay down the law. Democratic government meant that those who were governed selected the men they considered best fitted to conduct their centralized affairs, and these in turn did their best to discover the will of their constituents, the constituents on their part agreeing tacitly to be bound by the opinion of the majority. Some years ago the British Medical Association was reorganized on thoroughly democratic lines, to such an extent, indeed, that its constitution was often referred to as a model of what democratic organization should be. It allowed for the most ample reflection in the central bodies of the opinion of the mass, if the mass cared to make use of the machinery available. When the Insurance Bill was brought in the Association applied its machinery to the business of finding out what it was that practitioners wanted, and while they did not get all that they asked for, they secured probably as great a proportion of their demands as any body had ever won in a similar fight. They obtained *inter alia* one and three-quarter millions of additional money and defeated an attempt of the approved societies to secure control of medical benefit. In the first year of the Act the Association called a conference of Local Medical Committees, and the same practice had been followed each subsequent year, the Association endeavouring to carry out the desires then expressed. It was, of course, to the interests of the Association to do so. Out of about 14,000 practitioners on the panel, about 10,000 were members of the Association, and it was a significant fact that although the local committees could send anybody they liked as representatives to the conference, there had never been more than nine or ten non-members of the Association present. The Insurance Acts Committee had been delegated at each conference to carry out the executive work until the conference following, and that committee had fulfilled its trust in the belief that those representatives who at the conference had been in a minority would abide by the result.

At the last Conference a long discussion took place on

the new regulations for the treatment of discharged sailors and soldiers, and by a very large majority the Conference approved the action of the Insurance Acts Committee, and agreed that as an experiment the regulations were worth a trial. This resolution was sent to the Commissioners, who naturally supposed that it bound all those represented at the Conference. But the surprise of the Commissioners might be judged by their own, when it was found that at least two Panel Committees did not intend to be bound by the resolution, and had advised the local practitioners not to attend discharged sailors and soldiers under the new regulations. One committee, after an interview with the Commissioners, had changed its opinion and advised its members to fall into line, and the others would certainly have to do the same or take the responsibility of vitiating the experiment the profession had agreed to make. But the impression left on the outside public must be deplorable, as they must imagine either that the Conference was not thoroughly representative, or that it did not know its own mind, or that those present were not aware of the elements of democratic government.

At the same Conference a resolution was on the agenda claiming that the capitation rate for insurance practice should be increased from 7s. to 10s., and that the agreements for 1918 should not be signed until that concession had been obtained. This latter part of the motion (which was equivalent to saying that the practitioners should not renew their agreements) was withdrawn after discussion because of the evident impracticability of collecting within one month the resignations of 80 per cent. of panel practitioners (for it was agreed that no general resignation should be organized unless 80 per cent. of the practitioners were known to be prepared to act together). No public discussion had previously taken place as to the exact amount of increase to be pressed for, and there was no proof that the required number of individual practitioners throughout the country were prepared to take the extreme step of resigning. Obviously the first thing to do was to find out how far the individual practitioners were prepared to go, and to do this and collect the resignations could not be carried through in the brief time available. The method of negotiation, which consisted of presenting ultimatums without being sure of one's ground, was untenable. He did not at all agree with those persons whose idea of organization was to present a pistol at the head of bodies with whom negotiations were taking place. It was incumbent upon all who had to deal with the Government and other bodies that they should bring forward a reasonable case, and be prepared to discuss it on its merits. The Insurance Acts Committee had, in conformity with the resolution of the Conference, demanded the increase as from January, 1918, and would continue to press that when the increase was given it should take effect as from that date. A few committees represented at the Conference did not approve the scheme for collective bargaining, and if these committees insisted on standing aside—which he did not think they would in view of the unanimity of the profession on the need for an increased capitation fee—they could prevent the 80 per cent. of resignations from being obtained if it were found necessary to take that course. Obviously the first step to be taken by the Insurance Acts Committee was to find out how far it could rely on these committees. Every committee had now been asked to give a definite pledge to abide by the scheme for collective bargaining, and if that scheme broke down the responsibility would not rest on the Association. The Insurance Acts Committee had been asked by the Commissioners to send in a written statement of the case for the increase which would be forwarded to the Cabinet, and probably the Committee would have to discuss the matter with the Chancellor of the Exchequer. An increase of about 40 per cent. in remuneration was no light matter for the Government which had to find the money, but the profession had an exceedingly good case, and the Association was determined to press it to the best of its ability if loyally supported.

Shortly after the Conference the Cheshire and Burnley Panel Committees assumed that it was the intention of the Insurance Acts Committee to collect the resignations of practitioners by the required date—November 19th—and to put an immediate ultimatum to the Government. He wrote explaining the position, but these committees were not satisfied, and called a meeting at Manchester, at which

many things were said which would not have been said had the speakers realized what democratic government involved. Were all the committees who took the trouble to send representatives to the conference, as well as the Insurance Acts Committee and its subcommittees, to be stultified by action of this kind? The Panel Medico-Political Union—a body with a membership said to be over 2,000, scattered over the country, but with no collective mandate from the profession—had also circularized its members and advised them not to abide by the resolution on the new regulations. If individual panel committees were to go off at a tangent and individual practitioners were to take a line of their own, instigated by irresponsible outside bodies, there was an end of all effective organization.

Dr. Cox went on to say that an investigation of the central pool was to be made by the president of the Institute of Actuaries, who was being given full facilities by the Commissioners. After this actuarial investigation was completed, it was very likely that, in accordance with the suggestion of the Insurance Acts Committee, the present method of distribution would be reviewed and an attempt made to find a better method. Turning from matters of purely insurance interest, he proceeded to touch upon the proposed Ministry of Health. Dr. Addison on the previous Saturday (*BRITISH MEDICAL JOURNAL*, December 1st, p. 726) had made it evident that the Government was doing its best to reconcile the various conflicting interests with a view to the establishment of the new Ministry. The Minister of Reconstruction had invited representatives of the Association to meet him to discuss the medical aspects of the question, and as soon as definite information could be obtained the profession would be consulted. The last Representative Meeting had strongly endorsed the view that the new Ministry should place the clinical and preventive aspects of medicine on an equal footing. In the past the preventive work had always seemed to have preferential treatment in the central departments, with the result that local authorities undertaking new medical work had had every inducement to put it under the control of whole-time medical officers. The Association was anxious that the new Ministry should take it as an axiom that in clinical work the opportunity should first be offered to practitioners on the spot.

After dealing with the need for a substantial concession from the Treasury to the rural practitioner engaged in insurance work, which he hoped would soon be obtained, Dr. Cox concluded with a reference to the position of men on service. Though he was sure the average man honestly did his best to preserve the interests of his absent colleague, even the best efforts often had poor results. A great deal of the falling off in incomes was inevitable, owing to the death and removal of patients, the disinclination of some to go to a stranger for minor ailments, and of others to inform their new doctor that they already had a practitioner who was on service. Then it was often very difficult, if not impossible, to say definitely to which of two or more doctors a given patient belonged. But allowing for all this, it was the duty of everyone at home to look after the interests of the absent men, and in cases of doubt to give them the benefit.

In the course of discussion,

Major ELWIN NASH strongly supported the claims of the Association to represent the profession as a whole. Speaking also as a man on service, though not in general practice, he said that many of his colleagues were very dissatisfied with the amount of protection their practices were receiving.

Dr. JAMES GARDNER (Burnley) said, with regard to the Manchester meeting, that he came away from the Conference in London with the belief that the profession was to be organized at once. At Burnley they were of opinion that the Insurance Acts Committee had been very dilatory, and they thought they were justified in having a meeting to ascertain the actual situation. The resignations had not been sent in, and insurance practitioners were now bound to go on treating their patients for the whole of next year on the old basis. The Committee ought to have sent out notices at once to the Panel Committees asking them to consult their members as to the extreme step.

Dr. SIDLEY (Eccles) said that in his district the work of protecting the practices of the men on service was done for nothing by those at home, but they were ashamed.

nevertheless, of the smallness of the cheques they sent to the men who were away.

Another speaker thanked the Lancashire Panel Committee for calling the meeting, which he hoped would be a precedent. He added that Lancashire men did not wish the Insurance Act extended to dependants, as they valued their private practices much more than any kind of contract work.

Dr. MAIN (Salford) defended the Panel Medico-Political Union, which he said was not composed of scattered individuals but of blocks of men in various places. If it was not possible for a man to be a supporter of the Union and of the British Medical Association, one-third of the Union's council and a considerable proportion of its members would have to decide between the rival allegiances. As to the protection of the practices of absent men, it was often difficult to ascertain to what practitioner a patient belonged. The practice of one Salford doctor on service, originally worth £1,400 a year, had practically disappeared. The local committee had investigated the lists of all the men in the neighbourhood, but all except one showed decreased instead of increased income, and the exception was a man who had newly come into the neighbourhood and whose practice was growing, and even so, it in no degree explained the loss.

Dr. CAMPBELL (Wigan) spoke of his intention as secretary of the County Panel Committee to organize the county thoroughly, as it was felt that Lancashire was one of the most vital centres in the kingdom. He hoped that the Panel Committees of the various county boroughs would give their support.

A vote of thanks was heartily accorded to Dr. Cox and to the Chairman.

GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION.

WINTER SESSION, 1917.

SIR DONALD MACALISTER, K.C.B., President,
in the Chair.

EDUCATION COMMITTEE.

Inclusion of Latin in Preliminary Examination in General Knowledge.

THE Education Committee presented a further report on the compulsory inclusion of Latin in the preliminary examination in general knowledge. The report dealt with the part of the subject which in the session of November, 1916, was remitted for further consideration—namely, that dealing with the junior entrance examination, a test intended to meet the conditions of youths who leave school at the age of 15-16 years and of those who occupy a similar educational level. The considerations which led the Committee to take the view that Latin should be retained for the present in this examination were recapitulated, and further documents were put in, including a special report from the Rector of the Royal High School of Edinburgh (Mr. John Strong, M.A.), who agreed that there were no possible substitutes for Latin in the educational scheme suitable to a youth of 15 which could be said to be entirely satisfactory. The Committee recommended that for the present, in examinations which were entirely of the junior order and open to pupils of 16 and under, the subject of Latin should continue to be required. In the case of older candidates belonging to an intermediate group standing between the levels of the senior and junior certificates, who did not profess Latin, an intermediate portal might be established. The general standard of such an examination (for pupils of 17 to 18) would be distinctly higher than that of the present junior examination, and effect could be given to the proposal by appending a note to the present regulations governing the junior examination that an examination on the standard of the higher examination in science or in any one of the four subjects specified in the junior list might be substituted for Latin. The report also pointed out that for some years the number of entrants upon medical study had been increasing, from 1,397 in 1912 to 1,873 in 1916—a progressive increase, save for a slight falling-off in 1916 as compared with the previous year. The time seemed favourable for taking a first step towards the raising of the

standard of the entrance examination in medicine. If the conditions of entrance for the diploma in dentistry were relaxed, in view of the diminution in numbers of registered dentists, this should not be allowed to influence the discussion of the question. The Committee recalled the fact that in 1902 it had replied to a deputation from the British Medical Association to the effect that as soon as the Committee believed the requirement was practicable it was prepared to recommend to the Council the adoption as a general rule of the age of 17 for admission to the *Students' Register*. The report contained no recommendation.

Examinations in Secondary Schools in England.

The Education Committee submitted a report upon examinations in secondary schools in England. The Committee advised that until the new Board of Examiners, which was created in September last, had had time to complete the reorganization with which it was charged, no further action should be taken by the Council with reference to the conditions of the examination in general knowledge. If the scheme realized expectations the complicated problem with which the Council, in dealing with the preliminary education of the student, had been confronted in the past would be profoundly modified. Hitherto there had been no educational authority in the country to supervise and classify examinations; therefore the General Medical Council and the licensing bodies had been compelled to define and exact their own requirements in general education. Under the new arrangements all examinations to which the pupils of State-aided secondary schools were submitted would be under the control of a committee of experts representative in the broadest sense of purely educational interests. The Secondary Schools' Examination Council included representatives of all the universities, of the managing bodies of the State-aided schools, and of the teachers. The examination would be conducted under its supervision by the universities. There would be two examinations, the first the Schools' Examination, suitable for pupils of 16 and qualifying for university matriculation if passed with credit, and the second the Higher Schools' Examination, adapted for youths of about 18 years of age. Each school might be examined on its own syllabus; pupils would be put forward in classes rather than individually; in doubtful cases the school record would be taken into account, and the subjects included in the "pass" would be endorsed on the certificate. Admission to the examination would be, in the majority of instances, by way of a definite period of instruction in a secondary school, but arrangements would be made for the inclusion of those who approached by other than the usual channels. The success of the scheme demanded the co-operation of the universities and the professional bodies with the Board of Education. The great advantage which the scheme offered to this country could only be realized through the avoidance of any conflict of interests between the two grades of educational institutions and through granting to the schools complete freedom from external influences inimical to their true teaching work. In the near future probably all the general entrance examinations in the country which were conducted by or on behalf of the universities would be co-ordinated and classified, and it was to be hoped that those of the College of Preceptors would be included in the classification. The gradual advance of the standard of the entrance examination in medicine should then present no difficulty, as it would be possible to carry it out in strict harmony with the educational progress of the country. The Education Committee therefore expressed the view that the General Medical Council should be maintained in close touch with the Board of Education and the newly-established Secondary Schools' Examination Council. It would probably be found advantageous, however, to grant to the Students' Registration Committee even a greater measure of freedom than it had exercised in the past in dealing with the educational qualification of candidates who were above school age.

The report of the Committee embodied a report by two members who represented the General Medical Council at a conference of representatives of the professional bodies held in July. A proposal was then submitted that a Standing Committee of Representatives of the Professional Bodies should be formed, and that one member of this Standing Committee should have a place upon the

Secondary Schools' Examination Council. The latter part of this proposal was afterwards withdrawn, but the representatives of the Council held the opinion—which is endorsed by the Committee—that the purposes of the Council would be better served by direct relation with the Board of Education or any permanent committee it might appoint than they could be if approach were to be made through the suggested Standing Committee, though such direct relation need only come into action occasionally.

Dr. MACKAY said that the work of the secondary schools in England had been greatly hampered by the multiplicity of examinations. The establishment of the Secondary Schools' Examination Council made it possible to look forward to considerable progress in general education, the result of joint action by schools and universities, and each step would be taken in unison. His committee did not approve the proposal of Mr. Fisher to set up a standing committee from the professional bodies, which were 17 in number, and of extremely divergent aims.

Dr. MACKAY moved, and Sir ARTHUR CHANCE seconded, and it was agreed:

That as the professional bodies which demand an entrance examination are widely divergent in their aims, the Council is of opinion that they cannot be combined in a Joint Standing Committee, which might reasonably be expected to take united action. On the other hand, the Council would welcome the privilege of conference, from time to time, as occasion arises, with the Education Board or the Secondary Schools' Examination Committee.

Dr. MACKAY said that probably the Council would soon be called into consultation by the new examination body which was attempting to co-ordinate and standardize examinations, and accordingly moved the postponement of discussion of the subjects to be included in the junior examination in general education.

Dr. NORMAN MOORE seconded the motion, which was agreed to.

DENTAL EDUCATION AND EXAMINATION COMMITTEE.

Dental Nurses.

The Dental Education and Examination Committee reported that the Birmingham Education Committee, finding it difficult to secure suitable candidates for the normal dental staff of their school medical service, had inquired whether dental nurses comparable to medical nurses in respect of undertaking, under supervision, certain details of treatment could be employed without involving the supervising dentists in the liability to be charged with "covering." The President of the Council and the Chairman of the Committee were consulted, and a reply was sent to the effect that there would be no objection to the employment of dental nurses as proposed, provided that the supervision was of a real and not of a perfunctory nature.

Dental Education and Examination.

At the suggestion of Mr. C. S. TOMES it was agreed, in view of the appointment of a departmental committee on the Dentists Act, to postpone further a discussion on certain recommendations made in December, 1916, with regard to the course of study in dentistry.

REPRESENTATION OF REGISTERED DENTISTS ON THE COUNCIL.

THE PRESIDENT read a letter from the Lord President of the Privy Council stating the proposal of the resolution passed on the first day of the session affirming the advantage of some provision for the appointment to the Council of members representative of the dental profession appeared to require legislation, for which at present there seemed to be no adequate opportunity.

RESTORATION TO "MEDICAL REGISTER."

At the resumption of the public session on November 28th the PRESIDENT announced that the Acting Registrar was directed by the Council to restore to the *Medical Register* the name of William Joseph Ryan.

DISCIPLINARY CASES.

Sir Archibald Rodkin, the Legal Assessor, and Mr. Harper, the Solicitor to the Council, were in attendance.

The first case taken, adjourned from November 30th, 1916 (SUPPLEMENT TO BRITISH MEDICAL JOURNAL, December 9th, 1916, p. 161), was that of Robert Francis Ferris, M.B., Ch.B., of Burnopfield, co. Durham. At the former hearing the Council found the facts proved, but in view of the evidence as to general good character, suspended judgement until the present session.

Mr. Harper said that no further evidence against Dr. Ferris was alleged. Two medical men and three other men of high professional standing testified to his character and conduct in the interval, and the Birmingham Insurance Committee, the original complainant, expressed itself satisfied with the testimony. In reply to Mr. Steele, his solicitor, Mr. Ferris gave an undertaking as to his future conduct.

After the Council had considered the case in *camera*, the President announced the decision of the Council as follows:

Mr. Ferris, the Council has taken into consideration the evidence of good conduct during the interval which has been tendered in your behalf, and the assurance which you have given as to your future conduct, and has not seen fit to direct the Acting Registrar to erase your name from the *Medical Register*.

(To be continued.)

INSURANCE.

INSURANCE ACT IN PARLIAMENT.

THE TREATMENT OF DISABLED MEN.

MR. BUTCHER asked Sir Edwin Cornwall, on December 6th, whether he was aware that every one of the medical practitioners on the York panel, now resident in the area, had refused to attend upon invalid seamen and soldiers under the regulations recently issued by the National Insurance Commissioners (England), but had offered to continue to treat them upon the old (capitation) basis of treatment pending negotiations between the Commissioners and representatives of the medical practitioners, and were at present treating them gratuitously; whether he was aware that the Commissioners had refused to allow these persons to be treated upon the capitation basis provided for in the agreements between the Insurance Committee and the practitioners, and what provision was at present made by the Commissioners or the York Insurance Committee for adequate medical attention to the insured persons. Sir E. Cornwall, in reply to the first two parts of the question, referred to an answer given by him on November 26th, in which he said that the regulations were framed in accordance with the express desire of the authoritative representatives of the medical practitioners concerned, and that events subsequent to their issue had shown that the regulations were in fact acceptable to the great majority of such practitioners. As to the last part of the question, he said he was not aware that any insured persons were not receiving adequate medical attention in the area named, nor was there any reason why the attendance need be given gratuitously, for the Insurance Committee would pay any bills which were sent up in accordance with the authorized arrangements.

In reply to a similar question, on December 10th, by Mr. Ramsay MacDonald as to Leicestershire panel practitioners, Sir Edwin Cornwall replied in a written answer that the number of doctors referred to was not known to him; he was unaware of any medical practitioner who had refused to render treatment in any such case. He added that the doctors appeared to have been under some misunderstanding in the matter which a letter from the Commissioners, of which he was sending Mr. MacDonald a copy, would, he hoped, serve to remove. Sir Howell Davies received a similar reply to a question in regard to Bristol panel practitioners. It is understood that the reply of the Commissioners sent to Mr. MacDonald expresses the same views as were set out in the letter addressed to the Cheshire Medical Panel Committees, and published in the SUPPLEMENT of the JOURNAL on November 24th, p. 103.

INSURANCE GRANTS.

Mr. Duncan Miller asked the Chancellor of the Exchequer whether he was prepared to sanction the payment of the grants-in-aid for administration and medical benefits and for sanatorium benefit, the grants to provide for the expenses of medical referees, consultants, and of specialist consultants in connexion with medical benefit and the equipment, etc., of clinics, and also the nursing grant, all of which had been suspended since the outbreak of war, although appearing in the estimates for National Insurance. Mr. Bonar Law: The suggestion made in question will be carefully considered in connexion with the estimates of the Insurance Department for the coming year, but having regard to the general financial situation I cannot pledge myself to the revival of all or of any of those grants at the present time.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments are reported by the Admiralty: Fleet Surgeon J. A. Keogh, M.B., to the *Victory*, additional, for disposal. Staff Surgeon C. K. Bushe, M.D., to rank of Fleet Surgeon. Staff Surgeon L. P. Cope to the *Victory*, additional, for disposal. Temporary Surgeons: T. H. W. Idris to the *Esquad*; F. G. Hunt, M.B., to Chatham Hospital; H. Harvey to the *Amphitrite*; H. C. C. Joyce to the *Vindicta*, additional, for disposal. To be temporary Surgeon: D. M. Dickson.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon C. H. P. Atkinson to the *Vindicta*, for disposal. Surgeon Probationer W. E. McCormack to the *Alarm*. To be Surgeon Probationer: E. De L. W. Deane.

ARMY MEDICAL SERVICE.

Lieut.-Colonel A. W. N. Bowen, D.S.O., relinquishes the rank of temporary Colonel on re-posting.

Lieut.-Colonel S. A. Archer to be temporary Colonel whilst employed as Assistant Director of Medical Services of a Division.

Temporary Colonel Sir John Collier relinquishes his commission.

Temporary Lieut.-Colonel R. E. Kelly (Captain R.A.M.C.T.F.) to be temporary Captain.

ROYAL ARMY MEDICAL CORPS.

Temporary Colonel P. W. G. Sargent, D.S.O., M.B., F.R.C.S. (Lieutenant R.A.M.C.T.F.), relinquishes the rank of temporary Colonel and to be temporary Lieut.-Colonel on re-posting.

The following relinquish their commissions on appointment under the Ministry of National Service: Temporary Colonel J. Galloway, C.B. Temporary Majors W. B. Edwards, A. G. Andrews, N. S. Manning, F.R.C.S.I. Temporary Captains H. Owen, J. J. Robb, W. R. Reith, H. Bates, E. L. Jenkins, H. P. Gaston, J. C. Fisher, J. D. C. White, W. G. Galletly, J. Davies, T. W. E. Moreton. Temporary Lieutenants C. Alison, M.B., R. W. Johnstone, M.D., F.R.C.S.E.

Lieut.-Colonel A. R. Aldridge, C.S.I., C.M.G., M.B., relinquishes the acting rank of Colonel on re-posting.

Major A. S. J. Graham is seconded for employment under the Ministry of National Service.

Major P. J. Maret to be acting Lieut.-Colonel whilst in command of a medical unit.

Temporary Major E. D. Macnamara, M.D. (Captain R.A.M.C.T.F.), relinquishes his temporary commission on re-posting.

Temporary Majors relinquish their commissions: J. C. Briscoe, M.D., F.R.C.P., J. Kerr, M.D., W. A. Brend, M.B., J. F. Porter, M.D., T. M. Martin, M.D.

Temporary honorary Major B. Crothers relinquishes his commission.

Temporary Captain F. Herniman-Johnson relinquishes his commission on account of ill health and is granted the honorary rank of Captain.

Temporary Captains C. A. Dupont and J. D. Wilkinson relinquish their commissions on account of ill health contracted on active service.

The notifications regarding temporary Captains R. P. Nash and J. A. Smith published in the *London Gazette* of October 20th and November 14th respectively are cancelled.

Temporary Captain C. A. Keegan relinquishes his commission on account of ill health.

To be temporary Captains: Temporary Lieutenant H. T. H. Butt, W. T. Smith, M.B., A. C. Falkiner, M.B., J. N. Glaister, C. G. Monro, M.B.

Temporary Captains relinquish their commissions: J. R. Polson, M.D., W. W. Linington, F.R.C.S., J. B. Orr, D.S.O., M.C., M.B., D. E. Scott, M.D., J. E. Knox, M.B., R. I. Harris, A. R. Riddell, M.B., T. C. Routley, M.B., E. T. Jones.

Temporary Lieutenants to be temporary Captains: C. J. C. Macquarie, M.B., M. J. Ahern, C. W. Forsyth, M.B., R. Stansfeld, J. H. Hes, M.B., E. R. D. Macdonald, M.B., F.R.C.S.E., T. J. Lloyd, G. N. Kirkwood, M.B., A. W. Brodrick, M.B., G. W. Bury, M.D., F.R.C.S.E., F. B. Macdonald, M.D., P. A. Creux, J. F. H. Stallman, M.B., T. Marron, M.B.

The following are granted the honorary rank of captain: G. K. Allan, M.B., and C. H. Evers, late temporary Captains.

Temporary Lieutenant S. Y. Walsh, M.B., relinquishes his commission May 26th (substituted for announcement in the *London Gazette* of July 10th).

Temporary Lieutenants relinquish their commissions: W. Brennan, A. W. R. Stratton, J. A. A. Boddy, H. V. O'Shea, M.B., O. H. Woodcock, M.B., R. G. Griffin, J. G. Fleming, M.B., M. J. Walsh, M.B.

To be temporary Lieutenants: S. Spencer, C. Murphy, M.B., A. R. P. Scott, J. C. Johnson, G. C. Cossar, P. S. Clarke, F. J. Power, G. Ferguson, M.B., R. O'Connor, A. Bryans, H. S. Gabb, M.B., W. Cregar, M.B., H. Barber, M.D., F. Joyce, M.B., E. F. Lawson, M.B., M. J. O'Flynn, M.D., J. M. McCormack, M.B., A. G. Heron, M.D., F. C. Watson, R. J. MacMillan, M.B., A. S. Moorhead, M.B., F.R.C.S., F. Green, M.D.

Temporary Lieutenant Thomas Francis Collins is dismissed the service by sentence of a general court-martial October 22nd.

To be temporary honorary Lieutenants: G. H. V. Hunter, H. A. Haskell, C. S. Gilman.

TERRITORIAL FORCE.

ARMY MEDICAL SERVICE.

Temporary Colonel W. C. Beevor, C.M.G., M.B. (Lieut.-Colonel retired pay), relinquishes his temporary rank on vacating the appointment of Assistant Director of Medical Services, and is granted the honorary rank of Colonel.

ROYAL ARMY MEDICAL CORPS.

Majors (temporary Lieut.-Colonels) J. H. Ray, M.B., F.R.C.S., and A. Cooke, M.B., F.R.C.S., and Captains (temporary Majors) R. Ollershaw, M.D., F.R.C.S., and F. E. Tyldesley, M.D., relinquish their temporary rank and are restored to the establishment.

Major (temporary Lieut.-Colonel) R. M. West, D.S.O., M.D., to be Lieut.-Colonel.

Major J. A. Coupland, M.B., F.R.C.S., from permanent personnel, to be Major whose services are available on mobilization, and is restored to the establishment.

Major (temporary Lieut.-Colonel) G. A. Trapp, M.D., relinquishes his temporary commission on ceasing to command a field ambulance.

Major (acting Lieut.-Colonel) T. A. Barron relinquishes his temporary rank on ceasing to command a field ambulance, July 19th.

Major A. E. Hodder, D.S.O., to be acting Lieut.-Colonel whilst commanding a field ambulance, August 3rd.

Major A. Milne-Thomson, C.M.G., is seconded whilst holding an appointment as Assistant Director of Medical Services, and to be temporary Colonel whilst so employed.

Major L. P. Demetriadi, M.D., F.R.C.S., relinquishes his commission on account of ill health contracted on active service, and is granted the honorary rank of Lieut.-Colonel.

Majors J. W. Mackenzie, M.D., and J. B. Yeoman, M.D., F.R.C.S., and Captain D. Shannon, M.D., to be acting Lieut.-Colonels whilst commanding a stationary hospital.

Captain R. P. Pollard, from Attached to Units other than Medical, to be Captain.

Major (temporary Lieut.-Colonel) T. Kay, M.B., to be Assistant Director of Medical Services, and to be temporary Colonel whilst so employed.

Captains (acting Lieut.-Colonel) H. B. Low, M.C., M.D., and H. F. Wilkin, M.C., F.R.C.S., relinquish their acting rank on ceasing to command a field ambulance.

Captains (temporary Majors) A. C. H. McCullagh, M.B., J. R. Pooler, M.B., and R. S. Taylor, D.S.O., to be acting Lieut.-Colonels whilst commanding a field ambulance.

Captain (temporary Major) W. Cowie, M.B., relinquishes his commission on account of ill health contracted on active service, and is granted the honorary rank of Major.

Captain (temporary Major) J. M. Hunt, M.B., to be acting Lieut.-Colonel whilst performing the duties of administrator of a general hospital.

Captains F. W. C. Brown, M.B., and E. B. Argles are seconded whilst holding an appointment as Deputy Assistant Directors of Medical Services.

Captain (temporary Major) J. W. Keay, M.D., relinquishes his temporary rank on ceasing to command a field ambulance, November 8th, 1917.

Captain J. P. H. Davies, M.B., relinquishes his commission on account of ill health, and is granted the honorary rank of Captain, October 14th (substituted for notification in the *London Gazette* of October 3rd).

Captains C. R. Handfield-Jones, M.B., and P. G. Phillips, resign their commissions on account of ill health.

Captain J. F. Edmiston, M.B., from Deputy Assistant Director of Medical Services, to be Captain.

Captain B. Fawcett resigns his commission on account of ill health contracted on active service, and is granted the honorary rank of Captain.

Captain J. D. Allen, M.B., resigns his commission on account of ill health.

Captain J. S. Burton resigns his commission.

Captain A. S. Daly is seconded for duty with a general hospital.

Captain A. Gough, M.B., F.R.C.S., is restored to the establishment.

Captain P. W. Thompson resigns his commission on account of ill health contracted on active service, and is granted the honorary rank of Major.

Lieutenant H. J. Shanley, M.B., to be Captain.

Captains (temporary Majors) relinquish their temporary rank and are restored to the establishment: D. Douglas-Crawford, M.B., F.R.C.S.; J. Hay, M.D.

Captain H. W. Beedham, M.B., resigns his commission on account of ill health, November 15th (substituted for notification in the *London Gazette* of November 14th).

Captain E. Bromet relinquishes his commission on account of ill health contracted on active service, and is granted the honorary rank of Captain.

Captain J. Bradley, M.B., F.R.C.S., and Captain H. Mason, M.D., are seconded.

Captains G. M. A. Thomas, M.D., and W. W. Horton, M.D., resign their commissions on account of ill health.

Captains restored to the establishment: H. Armstrong, M.D.; W. C. Oram, M.D.; V. C. de Boynville, M.D.; J. Wharton, M.D.; W. R. Higgins, M.B.; R. H. Fagge, L. A. Rowden, M.B.

Captain J. MacMillan, M.C., M.B., to be acting Lieut.-Colonel whilst commanding a field ambulance.

Captain W. Brown, M.B. (acting Lieut.-Colonel) relinquishes his acting rank on ceasing to command a field ambulance, August 5th.

Lieutenant S. R. Walker to be Captain.

Lieutenant G. L. Matthews to be Captain, February 11th, 1916 (substituted for announcement in the *London Gazette* of March 14th, 1916).

VOLUNTEER FORCE.

City of Glasgow Regiment—3rd Battalion.—J. W. Methie, late Lieutenant R.A.M.C., to be Medical Officer with the temporary rank of Lieutenant.

Shropshire Regiment—1st Battalion.—J. McC. McCarthy to be Medical Officer with the temporary rank of Captain.

County of London Regiment—11th Battalion.—Medical Officer and temporary Lieutenant T. Halliwell to be temporary Captain.

Hampshire Medical Corps.—To be temporary Captains: A. E. Clark and A. C. D. Newton, late Lieutenants R.A.M.C.

Kent Medical Volunteer Corps.—T. W. Hinds, M.D., to be temporary Captain.

Suffolk Volunteer Regiment—1st Battalion.—A. Y. Pringle to be temporary Captain. 4th Battalion—H. G. Toombs to be temporary Lieutenant. 5th Battalion—T. H. Goodman to be temporary Lieutenant. 6th Battalion—C. W. Biden to be temporary Lieutenant.

City of Bristol Volunteer Regiment—2nd Battalion.—F. E. Peake to be Medical Officer and temporary Captain.

Midlothian Volunteer Regiment—11st Battalion.—R. Inch to be Medical Officer and temporary Lieutenant.

Somerset Volunteer Regiment—3rd Battalion.—Medical Officer and temporary Captain A. D. Willcocks, from 1st Battalion, to be Medical Officer and temporary Captain.

Glamorgan Medical Volunteer Corps.—Captain A. W. Anderson, late R.A.M.C., to be temporary Major.

Lancashire Medical Volunteer Corps.—T. B. Grimsdale to be temporary Major. H. E. Jones and J. Watson to be temporary Captains.

VACANCIES.

NOTICES REGARDING APPOINTMENTS.—Attention is called to a Notice (see Index to Advertisements—Important Notice re Appointments) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

BELFAST DISTRICT ASYLUM.—Medical Superintendent of Purdysburn Villa Colony Asylum. Salary, £700 per annum.

BRISTOL EYE HOSPITAL.—House-Surgeon. Salary, £120 per annum.

BRISTOL ROYAL INFIRMARY.—(1) House-Physician. (2) House-Surgeon. Salary, £120 per annum.

CARDIFF UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—Temporary Lecturer in Physiological Chemistry. Salary, £200 per annum.

CHELMSFORD: ESSEX EDUCATION COMMITTEE.—Assistant School Medical Inspector. Salary, £350 per annum.

CHILDREN'S INFIRMARY, Cleveland Street, W.—Assistant Medical Officer (female). Salary, £250 per annum.

DARLINGTON HOSPITAL.—House-Surgeon. Salary, £200 per annum.

FIFE COUNTY COUNCIL.—Assistant Tuberculosis Officer. Salary, £350 per annum.

GUILDFORD: ROYAL SURREY COUNTY HOSPITAL.—House-Surgeon. Salary, £250 per annum.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.—Two House-Surgeons. Salary at the rate of £100 per annum and £5 washing allowance.

HYDE BOROUGH EDUCATION COMMITTEE.—Woman Dentist to take charge of the dental clinic.

IVERNESS: NORTHERN INFIRMARY.—House-Surgeon. Salary, £3 3s. per week, and £1 1s. additional as war bonus.

KINGSTON-UPON-HULL CORPORATION.—Resident Medical Officer at the Infectious Diseases Hospitals. Salary, £400 per annum.

LEEDS CITY.—Woman Medical Assistant. Salary, £350 per annum.

LEWISHAM BOROUGH.—Assistant Medical Officer of Health and Medical Officer for the Municipal Maternity and Child Welfare Centre. Salary, £500 per annum.

NEW HOSPITAL FOR WOMEN, Euston Road, N.W.—Surgeon-in-Charge of Throat and Ear Department.

NOTTINGHAM CHILDREN'S HOSPITAL.—Resident Lady House-Physician and Anaesthetist. Salary, £250 per annum.

PLYMOUTH: SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House-Physician. Salary, £200 per annum.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.—Temporary Assistant Physician. Honorarium, £12 10s.

SOUTHAMPTON: ROYAL SOUTH HAMTS AND SOUTHAMPTON HOSPITAL.—Senior House-Surgeon. Salary, £300 per annum.

STOKE-ON-TRENT COUNTY BOROUGH.—Lady Medical Officer. Salary, £350 per annum.

STOKE-ON-TRENT: NORTH STAFFORDSHIRE INFIRMARY.—House-Surgeon (lady). Salary, £200 per annum.

SUNDERLAND: CHILDREN'S HOSPITAL IN CONNEXION WITH ROYAL INFIRMARY.—Resident Medical Officer. Salary, £200 per annum.

WALLASEY COUNTY BOROUGH.—Lady Assistant School Medical Officer. Salary, £300 per annum, plus war bonus of £37 10s.

WALSALL AND DISTRICT HOSPITAL.—Senior House-Surgeon. Salary, £250 per annum.

WEST HAM UNION INFIRMARY.—Temporary Assistant Medical Officer. Salary, £300 per annum.

WILLESDEN URBAN DISTRICT COUNCIL.—Temporary Assistant Medical Officer. Salary, £10 10s. per week.

CERTIFYING FACTORY SURGEONS.—The Chief Inspector of Factories announces the following vacant appointments: Kenilworth (Warwick), Killeshaundra (Cavan), Wolsingham (Durham), Yarmouth (Isle of Wight).

MEDICAL REFEREE.—Medical Referee under the Workmen's Compensation Act, 1906, for Hull, Hedon, Beverley, Great Driffield, Bridlington, Pocklington, Selby, Goole, and Howden County Courts, Circuit No. 16. Applications to the Private Secretary, Home Office, by December 27th.

To ensure notice in this column—which is compiled from our advertisement columns, where full particulars will be found—it is necessary that advertisements should be received not later than the first post on Wednesday morning. Persons interested should refer also to the Index to Advertisements which follows the Table of Contents in the JOURNAL.

APPOINTMENTS.

ATKINSON, H. L., M.R.C.S., L.R.C.P., District Medical Officer of the Cokermouth Union.

BOYES, A., M.B., Ch.B., Glas., Medical Officer for Mother and Infant Welfare and School Work in the County of Surrey.

FAIRCHILD, G. C., M.R.C.S., L.R.C.P., District Medical Officer of the Camelford Union.

JONES, C. R., M.B., Ch.B., Certifying Factory Surgeon for the Arnesby District, co. Leicester.

PATEY, W., M.D., District Medical Officer of the Newton Abbot Union.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

DEATHS.

FALENER.—On December 10th, at the Hermitage, Fulham Palace Road, S.W., Marie Louise (Minnie), the beloved wife of S. Falkner, M.R.C.S., L.R.C.P.

FISHER.—At Great Eccleston, Garstang, suddenly, on December 1st, Dr. Thomas Fisher, J.P., aged 63 years.

DIARY FOR THE WEEK.

FRIDAY.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos Street, W. 5.30 p.m.—Geographical Distribution of Human Diseases and their Control, by Colonel J. H. Tull Walsh, I.M.S. (ret.).

ROYAL SOCIETY OF MEDICINE.—Tuesday, 5 p.m., General Meeting of Fellows. Section of History of Medicine: Wednesday, 4.30 p.m., Exhibition of pictures, books, etc. 5 p.m., Dr. G. C. Peachey: The Two John Peacheys (Seventeenth Century). Dr. G. C. Cunston: (1) Morgagni and the Foramen Caecum; (2) The Death of King Henry II. Section of Dermatology: Thursday, 5 p.m., Cases. Section of Electro Therapeutics: Friday, 8.30 p.m., Mr. A. E. Baines: Interpretation of Certain Electro Physiological Phenomena.

INSURANCE.

THE DEMAND FOR AN INCREASED CAPITATION FEE.

THE Insurance Acts Committee of the British Medical Association has forwarded to the National Health Insurance Joint Committee the following memorandum on the reasons which led the last conference of representatives of Local Medical and Panel Committees to ask that the capitation fee for medical attendance under the National Insurance Acts should be raised to 10s.

Memorandum.

For more than two years past the stress of war conditions has been felt by the medical profession to an ever-increasing degree. In this, of course, their experience has only been the same as that of all classes in the nation who have not been profiting by those conditions, and members of the profession like many others have been willing as a patriotic duty to make the best of the circumstances and to work much more strenuously and much less profitably than would otherwise have been the case. Latterly, however, the economic stress has reached such a degree that practitioners in most areas have found it necessary to increase their fees either according to their individual necessities and methods or by local arrangements with their fellow practitioners. This may be supposed to meet the case as far as private practice is concerned, but in connexion with practice under the National Insurance Acts the contract is fixed according to an arrangement made in peace times, and with no reference to such economic conditions as now prevail.

Those members of the profession who are working under these Acts have been reluctant to raise any questions on this matter, or to make any actual proposals for increased remuneration, both because as part of an educated profession they wished to be fully persuaded as to the real necessity of the case and of the equity of any proposals they might make, and because they desired to act with the utmost degree of patriotism, and to bear on their own shoulders their increased burdens to the limit of what was fair to themselves and those dependent upon them.

At the conference of representatives of Local Medical and Panel Committees in June, 1915, representing the great majority of those committees throughout the country, resolutions were passed pointing out the need for a revision of the insurance rate of remuneration in so far as the war had led to a disturbance of the liability of medical attendance on the insured population, and the conference of October, 1916, declared that "owing to the great increase in the cost of living, insurance practitioners have a claim to an increase of remuneration, and that if such claim be not pressed at the present time this must be considered as a contribution to the national cause and without prejudice to the rate of remuneration after the war."

The profession is fully aware that if prices are proportionately raised all round no one is really any the better off for any increase that may be given in remuneration. But so general and considerable has been the rise in prices during the past year that it has become evident that if all classes except one or two raise the price of what they are able to contribute to the general well-being, those one or two classes are necessarily placed in a relatively disad-

vantageous position which eventually becomes almost intolerable. The conference of Local Medical and Panel Committees held in October last unanimously passed the following resolutions:

1. That because of the continuance of the war, and the uncertainty of its duration, it has become impossible to postpone the reconsideration of the rate of remuneration of medical practitioners under the Insurance Acts till the war is over.
2. That the increased cost of living and of carrying on practice, and other reasons, require an increase in the capitation fee as from January 1st, 1918.
3. That the present capitation fee of 6s. 6d., plus 6d. for domiciliary treatment, be raised to 10s., which shall cover the increased liabilities with regard to discharged sailors and soldiers and all the services now rendered to tuberculosis patients by panel practitioners.
4. That the Insurance Acts Committee be instructed to negotiate these terms with the Government, and to organize the profession forthwith in furtherance of this object.

Without prejudice to the consideration, some time in the not too distant future, of the general question of the adequacy or otherwise of the present remuneration for work under the Insurance Acts, the alteration in the situation brought about by the war amply justifies a demand for a substantial increase of that remuneration as long as that situation continues, at least to the extent indicated in the above resolutions. The present maximum capitation fee is 7s. 6d.; that asked for is 10s.

There are three ways in which conditions brought about by the war have affected disadvantageously to the medical profession financial arrangements agreed upon when service was accepted for National Insurance work. The most important of these is the great increase in the cost of living and of carrying on medical practice. The exact degree to which the cost of living has risen is probably more accurately known to the Government than to the profession, but it is admittedly very great. In the case of the medical profession it is peculiarly difficult to make a clear distinction, in respect of every item, between the cost of living and the cost of carrying on practice, but in a number of practices in which accounts have been carefully kept it has been found that quite apart from the cost of food and other necessities, and without taking into account the cost of drugs, the expense of carrying on practice has risen by 37 per cent. or more—that is to say, it has risen by 10 to 15 per cent. on the income derived from the practice. As compared with other professional men—for example barristers and civil servants—whose expenses have been increased by war conditions, medical men are under a peculiar disadvantage—namely, that whereas it is possible for most people to reduce their expenses to almost any degree they find necessary, the professional expenses of a doctor are to a large degree fixed; his travelling and surgery expenses cannot be cut down, and the fact that his practice ties him to a particular locality and often practically to a particular house, makes it extremely difficult to reduce his household expenses without injury to his professional income.

Secondly, the insurance risk of medical attendance has been increased by the withdrawal of millions of the more healthy lives among that part of the insured population (men) which makes the smaller call upon the profession in this respect, and the addition of considerable numbers of women and of elderly men who have returned to work

who make a relatively larger call. The total amount of work required has probably been diminished owing to the reduction in the total number of insured persons in civil life, but this diminution of work is relatively less than the reduction of total remuneration owing to the causes mentioned. The amount of medical attendance necessitated has also been relatively increased by the desire of the great majority of insured persons to be helped to keep on working even while unwell instead of taking more readily that rest of which they really stand in need. Returns of sickness benefit, which is only granted when the recipient is unable to work, are very fallacious as a guide in this matter.

Thirdly, in a great many cases the daughters of well-to-do families and the wives of men in comfortable circumstances who had to join the forces, or whose economic position has been adversely affected by the war, have entered into employment either from a wish to take their share in national service, or because work is easier to obtain and the opportunity of earning larger amounts than was previously possible has made work more attractive when obtained. These women thus added to the number of insured persons were as private persons a source of considerable income to medical men practising amongst them, and would have remained so under normal conditions.

The effect of these and other circumstances of minor importance has been entirely to alter the appropriateness of the present fee for National Insurance work, and it is safe to say that if these conditions had obtained at the time when the arrangements were made with the profession, the terms agreed upon would have been materially different. Those practitioners who are doing National Insurance work now feel that there is most urgent need of readjustment. It is eminently undesirable that a sense of economic injustice should in any case be allowed to stand in the way of the best possible work for insured persons, and the profession desires to bring its collective influence to bear upon each of its members to keep the work up to the highest standard. It is the more easy to do this if the rate of remuneration be raised in accordance with the altered conditions now prevalent, and for as long as they prevail. The profession feels that its present demand is justified both by the merits of the case and by comparison with the increases of remuneration that have been granted to other classes of the community that are doing work of national importance.

MEETINGS OF BRANCHES AND DIVISIONS.

MIDLAND BRANCH: HOLLAND DIVISION.

A MEETING of the Holland Division was held at Boston on November 26th, when Dr. WITHAM was in the chair. Dr. Wright was elected the representative of the Division on the Branch Council. The action of the Insurance Acts Committee as set forth in M. 17 was approved. Various matters affecting local conditions were reported by the SECRETARY, and the action taken by the members residing in Boston approved.

SOUTHERN BRANCH.

At the half-yearly general meeting of the Southern Branch, held in Southampton on November 22nd, 1917, when Dr. H. J. MAY was in the chair, Major H. S. SOUTTAR read the paper on the treatment of nerve injuries which is published in full this week. A discussion followed and a vote of thanks to Major Souttar was carried by acclamation. With the view of improving the attendance at the annual clinical meeting, the desirability of holding it either early in the autumn or in the spring was suggested.

MEETINGS OF THE PROFESSION.

SOUTHAMPTON.

At a meeting of the medical profession in the Southampton area held on July 13th it was resolved:

That in view of the difficulty of the "remaining" doctors getting accurate information this meeting recommends that each "absent" doctor on his return to Southampton should call on his old patients and obtain from them particulars of their having consulted any "remaining" doctors, and the "absent" doctor should be and is hereby authorized to make application to the "remaining" doctors for particulars of any attendance given, and for payment of the half fees earned, and that all doctors be so informed.

That this meeting recommends that the individual members of the profession should, owing to the difficulty of selling a practice, pay to the representative of any "absent" doctor (general practitioner) who dies on service, or to himself if

permanently and totally disabled on service, £10 if such dead or disabled practitioner was in practice on his own account, or £5 if in partnership, and that all doctors be so informed.

The two following riders to the second resolution were also adopted:

That it should apply to general practitioners only, and that the benefits should apply to those general practitioners absent from the town and from their practices.

That the widow of any doctor who received the benefit should have the right to succeed, so far as the grant would be concerned, to such practice.

THE ORGANIZATION OF THE PROFESSION.

THE Medical Secretary requests us to publish the following letter reparing an omission in his speech at Preston reported under this heading last week, p. 118:

Sir,

The York Panel Committee is anxious that I should publicly repair an omission in my speech at Preston where I referred to two Panel Committees—London and Kent—as having advised their constituents not to attend discharged disabled men under the new regulations. Dr. Lyth, Honorary Secretary of the York Committee, informs me that his own Committee took the same line, as also did the North Riding Panel Committee. I did not know these facts when I spoke at Preston, or I should certainly have included these two Committees among those which, by declining to be bound by the overwhelming vote of the Conference at which they were represented, had, in my opinion, acted in opposition to one of the fundamental principles of democratic government.

Yours faithfully,

ALFRED COX.

MOTOR CAR BADGE FOR MEMBERS OF THE ASSOCIATION.

THE motor car badge referred to on page 101 of the SUPPLEMENT of November 24th is now ready for issue to members of the Association, and may be obtained at the cost of 1s. on application to the Financial Secretary and Business Manager, 429, Strand, London, W.C.2. The badge is intended to be affixed by gum or paste to the inner surface of the wind screen. The badge will only be issued on the distinct understanding that the member to whom it is supplied will only use it when his car is engaged on professional or other purposes expressly authorized in the Motor Spirit Restriction Order No. 2 of 1917, and that the Association does not accept any responsibility for any improper use that may be made of the badge.

GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION.

WINTER SESSION, 1917.

SIR DONALD MACALISTER, K.C.B., President,
in the Chair.

(Concluded from p. 121.)

THE APOTHECARIES' HALL OF IRELAND.

SIR FREDERICK TAYLOR, in submitting the report of the Examination Committee on various matters relating to the Apothecaries' Hall of Ireland, said that the Final Examinations were taking place during that week, and the result of the examinations held in July called for no comment. He moved, and Dr. NORMAN WALKER seconded, a recommendation that the Irish Branch Council again be authorized to appoint for one year a deputy to be present on behalf of the Council at the professional examinations.

Dr. EDWARD MAGENNIS moved a contrary amendment, which found no seconder. He said that his desire had always been to find out in what respect the examinations of the Apothecaries' Hall had failed to satisfy the Council. Why was not the Hall reported to the Privy Council and given a chance to prove that it compared favourably with any licensing body in the kingdom, and that its examinations were conducted with strictness and impartiality? The Council had not even appointed an English or Scottish deputy, as it should have done; its deputies were nominees of rival licensing bodies.

The PRESIDENT pointed out that the resolution proposed by the Examination Committee was in accordance with a general instruction given to that Committee two years ago, and it was simply an administrative matter at that stage to pass the resolution in order that the Council might get what it was hoped would be a final report upon the examinations.

Sir JOHN MOORE said that there was no "inspection" of the Apothecaries' Hall. The examinations were, at the instance of the Privy Council, a conjoint matter between the Apothecaries' Hall government and the General Medical Council. In the table showing the results of the examinations held in July, 1917, two out of the three candidates had left the bodies to which they belonged, and had gone to the Apothecaries' Hall. That fact alone would justify a very close supervision over the examinations of the Hall.

Dr. MAGENNIS said that he was perfectly aware that there was no inspection, but he had an objection to a deputy. He proceeded to defend the status of the examiners.

The recommendation authorizing the Irish Branch Council to appoint a deputy was carried, with Dr. Magennis the only dissident.

DISCIPLINARY CASES.

Professional Relationship in Adultery Cases.

The Council considered, on November 30th and December 1st the case of Bertie Cecil Eskell, registered as of 26, Zealand Road, Bristol, M.R.C.S., L.R.C.P., Captain R.A.M.C., who was summoned on the charge that, being a registered practitioner, he abused his position by committing adultery with Mrs. Kathleen Margaret Dobson Mercer Adam, with whom and whose husband he stood in professional relationship. Two days previously to the hearing a decree *nisi* had been granted in the Divorce Court, and £2,000 damages awarded the petitioner, Mr. J. B. Mercer Adam, who was the complainant in this case. Mr. Horace Rowlands opened the case on behalf of Mr. Adam, who gave evidence as to the professional treatment of himself by Dr. Eskell, and stated that the defendant had also treated his wife medically. He had offered to pay Dr. Eskell for his professional services, but the doctor refused to accept any fee. Dr. E. C. Robertson-Pullarton, of Hampstead, said that he attended Mrs. Adam in her confinement in April last. He was of opinion that it would have been undesirable for her to have remained in India, as she had albuminuria. Dr. Eskell, in his evidence, denied professional relationship, and said that fees were never mentioned by Mr. Adam from first to last. Mr. R. W. Turner, who appeared for Dr. Eskell, claimed that his client's relationship with Mr. and Mrs. Adam was simply that of a guest, and that the adultery did not arise out of the relationship of medical man and patient. After the Council had deliberated in private, the President announced the Council's decision as follows:

Mr. Eskell, I have to announce that the facts alleged against you in the notice of inquiry have been carefully considered by the Council, and have been found proved to its satisfaction; and that the Council has, on the facts proved, judged you to have been guilty of infamous conduct in a professional respect, and has directed the Acting Registrar to erase from the *Medical Register* the name of Bertie Cecil Eskell.

James George Silver Jamieson, formerly in practice in London, was summoned to appear on the charge that, being a registered practitioner, he abused his position by committing adultery with a lady with whom and whose family he stood in professional relationship, of which adultery he had been found guilty in the Divorce Court in 1915, in a case in which he was co-respondent. Mr. Booth, solicitor for Mr. Jamieson, said that Mr. Jamieson had transmitted to him a document acknowledging receipt of a notice with regard to the charge, and admitting that the statements contained in that notice were substantially true, and that consequently he must submit to his name being removed from the *Register*. He stated, however, that professional relationship had ceased to exist some time before the occasion of the charge, and that many statements made against him in the Divorce Court were wholly untrue and others greatly exaggerated. He added that he married the respondent in 1915. The solicitor said that Mr. Jamieson admitted the charge and accepted the consequences, and put in his plea as in some degree mitigation, but not in any sense justification. The case having been considered *in camera*, the President announced that the Council had directed the name to be erased from the *Medical Register*.

Part-heard Case.

The case was opened before the Council on November 30th of Arthur Edward Gladstone, M.R.C.S., L.R.C.P., now of

Alexandria, New Zealand, whose counsel, Mr. Craig Henderson, pleaded for postponement on the ground that the doctor's statutory declaration, which was an essential part of his defence, was on its way from New Zealand and had not yet arrived. It was agreed to take the statutory declaration of the petitioner in the divorce suit out of which the charge arose as he might not be able to attend at a later session, and after this gentleman had been examined by Mr. Harper, the Council's solicitor, and cross-examined by the counsel for Dr. Gladstone, the further hearing of the case was adjourned till the next session.

Name Erased.

Ernest Wardman Wilbourn, L.R.C.P., L.R.C.S., of Huthwaite, Nottingham, was summoned to appear on the charge that, being a registered medical practitioner, he was, at the Nottingham Assizes in June last, convicted of feloniously having carnal knowledge of a woman without her consent, and was sentenced to three years' penal servitude. Mr. Harper said that the accused had applied to the Home Office for leave to be present that day, but leave had been refused.

Sir A. Bodkin read a letter from the defendant, dated November 15th, admitting the fact of his conviction and sentence, but absolutely denying that the offence was committed or even intended. He admitted that he had been guilty of grave indiscretion in allowing the woman in question to come into the tuberculosis dispensary, of which he was officer, when no third party was present, but his desire was not to send her away without attending to her case as she had come a distance of three or four miles. He pleaded for a certain period of probation, during which he would undertake not to engage in private practice.

The Council considered the case *in camera*, and the President announced that the conviction had been proved to the satisfaction of the Council, and that the Acting Registrar had been directed to erase the name from the *Medical Register*.

Charge of Covering Uncertified Midwife.

The case of Edward White, L.S.A., M.R.C.S., L.R.C.P., of 2, Green Park, Bath, which had been adjourned from May, 1917 (SUPPLEMENT TO BRITISH MEDICAL JOURNAL, June 2nd, 1917, p. 125), in order to give the defendant an opportunity of reconsidering his whole position in relation to the matter, was next taken. The charge was of covering a woman whose name had been removed by the Central Midwives Board from the roll of midwives.

Dr. White now attended and produced certain testimonials, including one from Dr. Francis Fosbery of Bath, who said that he had known him for twenty years in Bath, and could testify that since his appearance before the Council in May his practice had been conducted with the utmost propriety. The clerk of the Bath Insurance Committee also wrote that Dr. White had been on the panel since the beginning, and had been one of the most careful of practitioners in granting certificates for sickness and disablement benefit. Two other testimonials from medical men were put in.

Mr. Bertram, who represented the Central Midwives Board, the complainants in the case, said that, following a practice which he understood the Council did not disapprove of, the Central Midwives Board had made inquiries from the local authority regarding the case, and he read a letter from the town clerk of Bath, dated October 22nd, in which it was stated that Dr. W. H. Symons, the medical officer of health for the city, died in August last, but the present acting medical officer had no adverse report to make upon Dr. White's conduct since May, and, moreover, that Dr. Symons shortly before his death had stated to the writer that it was his intention to submit a favourable report upon Dr. White's conduct.

After the case had been considered *in camera*, the President announced the decision of the Council as follows:

Mr. White, I have to announce that the Council, having considered the testimonials as to character which have been tendered on your behalf, and the assurance which you have given as to your professional conduct in future, has not seen fit to direct the Acting Registrar to erase your name from the *Medical Register*.

Dental Case.

The Council considered, on November 30th, the case of John Stanley Francis, L.D.S., of 59, Cambridge Street, W., with regard to whom a report was presented by the Dental Committee. Mr. Francis was originally registered in 1902, but in 1905 his name was erased from the *Dentists' Register* because no answer had been received to the customary notices sent to him. In 1908 he telephoned to the Registrar on the subject of the erasure of his name, but, although letter and application form for restoration were sent to him, no reply was received. The Committee reported that in 1910 he was convicted at Marylebone Police Court of assault and wilful damage, and later at the same police court, and again at another, of being drunk and disorderly and using obscene language. In August last he applied for restoration to the *Register*, and as his papers were in order the restoration certificate was issued, but his record of convictions was referred to the Dental Committee. He maintained that the first was a wrongful conviction; the other convictions he did not question. The Council, after deliberating in private, decided that the convictions had been proved, but, in order to give Mr. Francis the opportunity of showing that he had reformed, judgement was deferred until November, 1918, when he would be called upon to produce references as to his character and conduct in the interval.

Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are announced by the Admiralty: Staff Surgeon T. R. L. Jones to the *Pembroke*, additional, for disposal; Temporary Surgeons: C. Gardiner Hill to the *Frid*, additional, for disposal; C. M. Ryley, M.B., to Chatham Hospital; W. J. Tison to Hospital ship *Garth Castle*.

ROYAL NAVAL VOLUNTEER RESERVE.

To be Surgeon Probationer: W. W. Dow.

ARMY MEDICAL SERVICE.

Temporary Colonels to be temporary Surgeon-Generals: Sir Willmot T. Herringham, C.B., M.D.; Sir J. Rose Bradford, K.C.M.G., C.B., F.R.S., M.D.; Sir Bertrand E. Dawson, K.C.V.O., C.B., M.D.; Cuthbert S. Wallace, C.M.G., F.R.C.S.; Sir Berkeley G. A. Moynihan, C.B., M.B., F.R.C.S.

Lieut.-Colonel K. J. Greig, C.M.G., Reserve of Officers, relinquishes the rank of temporary Colonel on reposting.

Lieut. Colonels to be temporary Colonels whilst employed as Assistant Directors of Medical Services of Divisions: E. W. W. Cochran, M.B., L. N. Lloyd, C.M.G., D.S.O., J. H. Campbell, D.S.O.

Temporary Lieut.-Colonel R. E. Kelly (Captain R.A.M.C.T.F.) to be temporary Colonel (correction of announcement published last week).

ROYAL ARMY MEDICAL CORPS.

Major B. S. Bartlett retains the acting rank of Lieut.-Colonel whilst commanding a casualty clearing station.

The undermentioned relinquish the acting rank of Lieut.-Colonel on reposting: Major (temporary Lieut.-Colonel) T. J. Wright, D.S.O., Captain (temporary Lieut.-Colonel) A. Irvine-Fortescue, M.B.

Majors to be acting Lieut.-Colonels whilst in command of a medical unit: P. C. T. Davy, C.M.G., M.B., R. H. Bridges, D.S.O.

Major E. T. Potts, D.S.O., M.D., to be acting Lieut.-Colonel whilst employed as Assistant Director of Medical Services of an army.

Temporary Major F. L. Collie, M.B., relinquishes his commission.

Captain H. A. T. Fairbank, F.R.C.S. (R.A.M.C.T.F.), to be temporary Lieut.-Colonel.

Temporary Captain F. F. Muecke, M.B., F.R.C.S., relinquishes the acting rank of Lieut.-Colonel on reposting.

Temporary honorary Captain A. M. Westwater to be temporary honorary Major.

Temporary Captain J. B. Scott, M.B., relinquishes his commission on appointment to the Ministry of National Service.

Temporary Captains relinquish their commissions: F. A. Anderson, M.C., M.B., D. Macnish, M.B., P. M. Ragg, M.B., A. F. Elliott, M.B., A. Burns, M.B., C. W. Ensor, H. A. Cutler, M.B., W. Jameson, A. R. Muir, R. E. Thomas, M.D., T. Davidson, M.B., A. J. Couper, M.B., C. C. Bullmore, F. E. Wynne, M.B., K. J. Aveling, M.B., G. Pollock, M.D., F. J. McGlade, M.B., R. S. Jenkins, T. W. G. Hoeg, M.B., L. J. H. Oldmeadow, M.D., F.R.C.S.E., J. E. R. Orchard, J. J. Anning, T. J. Simpson, M.B.

Temporary Captains relinquish their commissions on account of ill health: A. J. Anderson, M.B., G. B. Flux, M.D.

Temporary Lieutenants to be temporary Captains: A. W. P. Pirle, M.B., J. Paterson, M.B., J. R. Fleming, D. O. Richards, M.B., W. C. P. Barrett, M.B., G. O'N. Waddington, T. P. Lincham, M.B., L. G. White, M. Golding, W. Simpson, M.B., J. B. Lester, M.D., V. C. Montgomery, M.B., A. H. Macklin, M.B., W. D. Kirkwood, M.D., F. A. Godson, M.B., E. W. Hall, J. J. O'Mullane, W. M. G. Guinness, M.D., B. G. H. Connolly, M.B., C. L. Warke, R. Cope, J. G. Macqueen, M.B., J. C. L. Day, A. Leeming, M.B., G. Cooper, M.D., C. Murphy, M.B., W. E. Harrows, M.D., E. W. Milne, M.B., S. E. Holder, T. F. Murphy, R. C. Corbett, M.B., A. MacMillan.

Temporary honorary Lieutenants W. F. Matthews, of St. John Ambulance Brigade Hospital, and C. G. Hitchcock to be temporary honorary Captains.

Temporary Lieutenants relinquish their commissions: W. T. Morton, W. L. Walker, M.B., T. B. Stedman, M.D., J. B. McEwan, M.B., R. C. de C. Wheeler, M.B.

C. R. Bird to be temporary honorary Lieutenant.

INDIAN MEDICAL SERVICE.

Lieut.-Colonel P. P. Kilkelly, I.M.S., to be Residency Surgeon in the Western States of Rajputana, August 3rd.

Captains to be Majors, September 1st, 1917: C. E. Palmer, M.B., P. E. M. Newland, L. A. H. Lack, M.B., E. J. C. McDonald, J. F. Boyd, N. S. Sodhi, W. C. Gray, M.B.

The services of Lieut.-Colonel C. H. James, C.I.E., have been placed temporarily at the disposal of the Chief Commissioner, Delhi, from October 1st, or subsequent date on which he takes up his duties as Professor of Operative Surgery at the King Edward Medical College, Lahore.

Lieut.-Colonel W. W. Clemesha, M.D., to be temporary Colonel whilst employed as Assistant Director of Medical Services, July 1st (substituted for notification under "Army Medical Service" in the *London Gazette* of August 31st).

SPECIAL RESERVE OF OFFICERS.

ROYAL ARMY MEDICAL CORPS.

Lieutenants to be Captains: R. V. Clarke, W. Yeoman, M. A. White, S. C. Swinburne.

Lieutenant Alexander Duguid, M.B., is dismissed the service by sentence of a general court-martial (August 13th).

To be Lieutenants: K. J. A. Gillanders, M.R., from Glasgow University Contingent O.T.C.; W. H. Rowden, M.B., from Leeds University Contingent O.T.C.; J. Thompson, M.B., from Edinburgh University Contingent O.T.C.; W. B. Buer, G. E. Birkett, M. B. Gunn.

OVERSEAS CONTINGENTS.

CANADIAN ARMY MEDICAL SERVICE.

D.A.D.M.S.: Temporary Major G. G. Greer, M.C., C.A.M.C., vice Major J. S. Jenkins, D.S.O., C.A.M.C.

CANADIAN ARMY MEDICAL CORPS.

Temporary Major C. F. C. Hazzard, from Canadian Light Horse, to be temporary Major.

Temporary Captain (acting Major) A. L. Jones to be temporary Major.

Temporary Major (acting Lieut.-Colonel) R. Wilson relinquishes the acting rank of Lieut.-Colonel on ceasing to be specially employed.

Temporary Captain (acting Major) A. MacKay relinquishes the acting rank of Major.

Temporary Captain F. V. Woodbury to be acting Major.

TERRITORIAL FORCE.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel (Brevet Colonel) F. H. Westmacott, F.R.C.S., and Captains H. H. Markham and M. D. Wood, M.D., are restored to the establishment.

Major (temporary Lieut.-Colonel) W. A. Wetwan relinquishes his temporary rank on ceasing to command a casualty clearing station.

Major G. Hall, C.M.G., M.D., is restored to the establishment.

Captain (temporary Major, acting Lieut.-Colonel) W. D. Sturrock, M.D., reverts to the temporary rank of Major on ceasing to command a field ambulance, with precedence as from September 11th, 1915.

Captain (temporary Major) E. R. Carling, M.B., F.R.C.S., relinquishes his temporary rank, and is restored to the establishment.

Captain J. Grace, M.B., and C. A. Moore, M.B., are seconded.

Captain J. H. Baldwin resigns his commission on account of ill health, and is granted the honorary rank of Captain.

Captain D. MacP. Taylor, M.D., relinquishes his commission on account of ill health contracted on active service, and is granted the honorary rank of Captain.

Captain H. A. P. Robertson, M.B., from a field ambulance to be Captain.

EXCHANGE.

M.O. with Field Artillery brigade in France desires exchange to hospital or other unit in England.—Address, No. 4100, BRITISH MEDICAL JOURNAL Office, 429, Strand, W.C.2.

VACANCIES.

NOTICES REGARDING APPOINTMENTS.—Attention is called to a Notice (see Index to Advertisements—Important Notice re Appointments) appearing in our advertisement columns, giving particulars of vacancies as to which inquiries should be made before application.

BARNSELY BECKETT HOSPITAL.—Second Lady House-Surgeon, Salary, £225 per annum.

BEDFORD COUNTY HOSPITAL.—(1) House-Surgeon; (2) House-Physician. Salary, £174 10s. and £152 10s. per annum respectively.

BIRKENHEAD BOROUGH HOSPITAL.—Junior House-Surgeon, Salary, £170 per annum.

BRISTOL EYE HOSPITAL.—House-Surgeon. Salary, £120 per annum.

BRISTOL ROYAL INFIRMARY.—(1) House-Physician; (2) House-Surgeon. Salary, £120 per annum.

CARDIFF UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—Temporary Lecturer in Physiological Chemistry. Salary, £200 per annum.

HOSPITAL FOR SICK CHILDREN. Great Ormond Street, W.C.—Two House-Surgeons. Salary at the rate of £100 per annum and £5 washing allowance.

KINGSTON-UPON-HULL CORPORATION.—Resident Medical Officer at the Infectious Diseases Hospitals. Salary, £400 per annum.

MANCHESTER ROYAL INFIRMARY.—Resident Surgical Registrar at the Central Branch. Salary, £200.

NOTTINGHAM CHILDREN'S HOSPITAL.—Resident Lady House-Physician and Anaesthetist. Salary, £250 per annum.

QUEEN'S HOSPITAL FOR CHILDREN. Hackney Road, E.—Temporary Assistant Physician. Honorarium, £12 10s.

ROCHESTER: ST. BARTHOLOMEW'S HOSPITAL.—Senior Resident House-Surgeon. Salary, £300 per annum.

SALOP COUNTY COUNCIL.—Temporary Assistant School Medical Officer. Salary, £400 per annum.

SOUTHAMPTON: ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Senior House-Surgeon. Salary, £300 per annum.

STOKE-ON-TRENT: NORTH STAFFORDSHIRE INFIRMARY.—House-Surgeon (lady). Salary, £200 per annum.

WALLASEY COUNTY BOROUGH.—Lady Assistant School Medical Officer. Salary, £300 per annum, plus war bonus of £37 10s.

WALSALL AND DISTRICT HOSPITAL.—Senior House-Surgeon, Salary, £250 per annum.

To ensure notice in this column—which is compiled from our advertisement columns, where full particulars will be found—it is necessary that advertisements should be received not later than the first post on Wednesday morning. Persons interested should refer also to the Index to Advertisements which follows the Table of Contents in the JOURNAL.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 5s., which sum should be forwarded with the notice not later than the first post on Wednesday morning in order to ensure insertion in the current issue.

BIRTH.

KEELING.—On December 16th, at Attleborough, Norfolk, the wife of G. S. Keeling, M.D.—a son.

DEATHS.

ANDERSON.—On December 17th, at Alde House, Aldeburgh, Suffolk, Elizabeth Garrett Anderson, M.D., aged 81. Funeral Friday, December 21st, 2.30 p.m., Aldeburgh. Memorial service at Christ Church, Endell Street (Military Hospital), on Saturday, December 22nd, at 11 a.m. No flowers by request.

ROBSON.—Killed in action, on December 2nd, 1917, aged 30 years, Captain Charles Henry Robson, M.B., R.A.M.C., the dearly loved husband of Winifred Irene Robson (née Taylor), of 47, Roxburgh Terrace, Whitley Bay, and oldest son of Mr. and Mrs. Alfred Robson, of 25, Victoria Avenue, Whitley Bay.

SWANN.—On November 28th, through sinking of ss. *Apapa* by enemy action, Alexander James Thompson Swann, M.B., Ch.M., D.P.H., Medical Officer, West African Medical Staff, Nigeria, beloved husband of Effie Jemima Cassels or Swann, L.R.C.P. and S.S. Eddlehurst, Eastwood Avenue, Giffnock, near Glasgow.

THOMPSON.—On December 5th, at Boxford, Suffolk, Alfred Thompson, L.R.C.P. Lond., M.R.C.S. Eng., aged 65.

RURAL PRACTITIONERS AND MILEAGE.

The last conference of Local Medical and Panel Committees passed three resolutions on the subject of mileage. The first asked the Insurance Acts Committee to take steps to have the arrangements for mileage improved under the scheme for treating discharged disabled sailors and soldiers; the second recorded strong objection to the mileage allowance for this purpose, and pressed for the same scale of payment as that allowed for attendance on serving soldiers; while the third instructed the Insurance Acts Committee to press for an increased mileage grant to rural practitioners generally. These, together with the other resolutions of the conference, were communicated in writing to the Insurance Commissioners on November 5th. On November 15th a deputation from the Executive Subcommittee of the Insurance Acts Committee waited upon the Insurance Commissioners, and after discussion of the mileage question it was agreed that certain detailed figures from members of the deputation in rural practice should be forwarded to the Commissioners. On November 20th the Medical Secretary wrote to the Insurance Commissioners stating the case for a review of mileage allowances, both general and in connexion with attendance on invalided sailors and soldiers, and pressing the Commissioners to induce the Treasury to make an immediate increase in the amount.

The result of the action of the Insurance Acts Committee on behalf of rural practitioners was announced briefly last week. The full text of the letter from the Commissioners is as follows:

December 19th, 1917.

Sir,

I am directed by Sir Edwin Cornwall to refer to your letter of November 20th, and to the representations which were made on behalf of rural practitioners at the conference with the Insurance Acts Committee on November 15th, and to state that the Joint Committee have been authorized to disburse an additional mileage grant as from January 1st, 1917, which will permit of a substantial increase in the special payments made to rural practitioners in respect of mileage, and will also permit of extra payments for mileage under the scales laid down in Regulations for the treatment of temporary residents and for invalided soldiers and sailors.

Sir Edwin Cornwall would be glad if two or three representatives of your Committee could attend here at an early date with a view to a discussion on points of detail with representatives of this department as to the general basis of distribution of this additional grant.

I am to add that this question has, as you are aware, been considered, on the request of your Committee, as a separate question, not involving the larger issues raised by the general application for increased remuneration put forward by the Conference of Panel Committees for the consideration of the Government.

I am, Sir, your obedient servant,

(Signed) E. HACKFORTH.

Thus the Insurance Acts Committee, acting on behalf of the Panel Committees, has succeeded in securing a prompt and satisfactory settlement of one of the important matters discussed at the recent conference.

SELF-GOVERNMENT OF THE MEDICAL PROFESSION.*

BY

JOHN CAMPBELL, M.A., M.D., F.R.C.S. ENG.,

BELFAST.

THERE has recently been some correspondence in the *BRITISH MEDICAL JOURNAL* regarding the organization of the medical profession. This brings to mind some of the various attempts in the same direction which have been made at various times during the past thirty years, and also recalls local efforts towards co-operation which have engaged the attention of the Ulster Branch and of the Ulster Medical Society on several occasions. These movements have been spasmodic; they have been brought about by some more or less temporary irritation; and they have subsided without leaving the profession in a much better position than it was. They failed to lead to any substantial general improvement, because they only arose to meet some pressing local requirement, and, on that account, did not go to the root of the matter.

The time is appropriate for considering the present and the future position of the profession, owing to the fact that the victorious ending of the war, for which we all hope, will set free a large number of men, some of whom will return to gather up the remnants of the practices which they left at the call of duty, others of whom will desire to settle down as newly-qualified practitioners, to make their way as best they can, and all of whom will have to engage in the struggle for existence with those who have been steadily pursuing their work at home. Beyond all these there are the students now attending the medical schools who will be coming into competition with the men already qualified. We have at present 403 medical students in Queen's University. Whatever the condition may be in England and Scotland, the information to be got about the Irish schools shows them to be very flourishing. These considerations suggest that there is probably a hard time before the medical profession. In the past the profession has been at best a struggling one. In the future the total amount of remuneration available from the community will be spread over a larger number of men and women doctors than hitherto, which is equivalent to saying that the average income will be less for the individual man. The difficulty of making ends meet will be greater even than it has been. We, as a profession, must look at the matter from this point of view. There will probably be work enough for all, but we all know that the doctor may be very busy and, at the same time, be making only a small income. Every medical man, from the nature of his calling, must do a considerable amount of gratuitous work.

The problem is how to make the available income equal to the demands of the members of the profession, or to keep the numbers of those entering the profession within such limits as to enable every man to get a decent living. The plan of setting out a local scale of fees has been tried time after time and found wanting. We have in our own

* Read at a meeting of the Ulster Branch of the British Medical Association on November 22nd, 1917.

society meetings agreed to a minimum standard of fees and forgotten our pious resolutions as soon as we were outside the room in which we had met. The alternative of cutting down numbers on the threshold of the profession has not been attempted. Any one who can pass the meagre standard of the entrance examinations can begin his studies, and, with a moderate amount of exertion, can become fully qualified. The majority of those who enter the profession are without capital. Necessity compels them to scramble for what they can get, and the lot of many is in consequence far from enviable.

How can we improve the position? I wish to suggest that we can most readily do so by getting more representation for the profession on the General Medical Council. At first sight it may appear that because the General Medical Council is wholly composed of medical men it is quite representative of the great body of medical practitioners. This is not so. The Council is composed of thirty-eight members. Of these, five are chosen by the King on the advice of the Privy Council, and twenty-seven are chosen by the Universities, the Colleges of Physicians and Surgeons, and the Apothecaries' Halls. This leaves only six direct representatives chosen by the profession—an inadequate number to look after the interests of 43,000 men, the number on the *Medical Register* for 1915. The twenty-seven representatives of the teaching and examining bodies are, as individuals, no doubt sympathetic to the struggling practitioner, but they are on the Council not to represent him but to protect the interests of the corporations which selected them. Now, the interest of a teaching or examining body is by no means the interest of the practising profession. Indeed, it may be fairly regarded as hostile in fact though not in intention. The universities and colleges desire to attract students. The more students they have the more successful they are, and the better their teachers are remunerated. But the more students they can draw in the larger will be the number of qualified men they will turn out, and the more severe will be the competition in the professional struggle for existence.

Ireland had one member for its 3,060 practitioners in 1915; Scotland had one for its 4,173; England and Wales had four members for 26,470, or one representative for each 6,617 practitioners. There were also 8,867 men serving in the navy and army or resident abroad who have no representation. If we take the Irish proportion as fair, obviously England and Scotland are entitled to at least ten representatives instead of five. Practitioners in the services and those resident abroad are entitled to three representatives. This makes an addition of eight to the General Medical Council, giving, with the present six, a total of fourteen direct representatives from the profession. While such an arrangement as this would not give the direct representatives a preponderance in the Council, it would greatly increase their influence. Amongst reforms which might be accomplished under such a scheme of self-government for the profession priority of place should be given to a uniform entrance examination for the medical students of the whole three kingdoms. A higher minimum standard of entrance examination would raise the position of the profession, and at the same time give the profession control over the candidates for admission and enable it to prevent overcrowding. Moreover, the individual medical schools would not suffer as they do now when one of them raises its standard, and so empties its class-rooms.

The British Medical Association could perform a useful and necessary work by taking steps to obtain greater proportional representation for the profession on the General Medical Council.

SOUTH AFRICAN COMMITTEE.

A MEETING of the South African Committee was held at the Institute of Medical Research, Johannesburg, on June 26th. The following members were present: Drs. Watkins-Pitchford, Baumann, Bidwell, Dr. Drury, Napier, Howell-Davies, and A. Jasper Anderson (Honorary Secretary). In the absence of the President (Sir Kendal Franks), Dr. WATKINS-PITCHFORD was elected to the chair.

Representatives on South African Committee.—The HONORARY SECRETARY read the names of the Representatives on the Committee appointed by the Branches:

Cape of Good Hope—Western Province Branch: Professor Jolly (President), Dr. A. Jasper Anderson, Dr. Hugh Smith, Dr. I. A. W. Beck.

Cape of Good Hope—Eastern Province Branch: Dr. H. F. Bell-Walker (President), Dr. Dr. Drury.

Border Branch: Dr. Lowndes (President), Dr. Ganteaume, Dr. Barcroft Anderson.

Orange Free State and Basutoland Branch: Dr. Manning (President), Dr. de Keek.

Pretoria Branch: Dr. Howell-Davies (President), Dr. Dunstan.

Witwatersrand Branch: Dr. Watkins-Pitchford (President), Sir Kendal Franks, Dr. E. P. Baumann, Dr. F. Napier.

Rhodesian Branch: Dr. W. M. Eaton (President), Dr. E. H. Strong.

Natal Coastal Branch: Dr. Aymer Dumat (President), Dr. Campbell-Watt.

Resignation of President and Election of Officers.—A letter was read from Sir Kendal Franks stating that he did not wish to be elected President of the newly elected Committee on the grounds that his health was not sufficiently good for him to devote the amount of time and energy required for that office and thanking the Committee for the honour and support given to him. Sir Kendal Franks's resignation was accepted with regret, and a resolution was passed thanking him for the great services which he had rendered to the Committee and expressing the hope that he would still be able to take an active part in the work of the Committee. Dr. A. Jasper Anderson was unanimously elected President, Dr. Watkins-Pitchford Vice-President, and Dr. A. W. Reid, Assistant Medical Officer of Health for Cape Town, Secretary. Dr. J. Barcroft Anderson was unanimously re-elected Honorary Treasurer. Dr. Bidwell agreed to act as Secretary to the Committee during the meeting.

Formation of New Branches and Alteration of Branch Rules.—Correspondence was read between the Honorary Secretary and the Medical Secretary of the British Medical Association with regard to the formation of new Branches and the alteration of rules of Branches. It was proposed by Dr. Bidwell and carried that the alteration of rules of any existing Branch in South Africa should be subject to the approval of the South African Committee and that the Secretary should write to the Medical Secretary to see if that power can be given to the South African Committee. It was also resolved that a copy of the Memorandum and Articles of Association and By-laws of the British Medical Association and the Regulations of the South African Committee should be supplied to the Secretary of each Branch to be kept in a place of security accessible to the President and Secretary of each Branch.

Medical Defence.—The HONORARY SECRETARY reported that arrangements had been made with Lloyd's agents, Messrs. C. L. Andersson and Co., Johannesburg, with regard to medical defence. The arrangements were that Lloyd's had agreed to insure medical practitioners through the South African Committee for the sum of £2 plus 2s. 6d. stamp duty against actions for alleged professional malpraxis, neglect, or mismanagement. The policy to cover £1,000 in any one action with a maximum of £3,000 per annum. Messrs. Andersson had agreed to hold a practitioner covered from the date he advised the Honorary Secretary of his intention to take out a policy.

Medical and Pharmacy Bill.—The PRESIDENT reported that the Subcommittee of Representatives of the Cape of Good Hope Western Province Branch with regard to the Medical and Pharmacy Bill had met and had appointed Professor Jolly and himself to give evidence before the Select Committee of the Senate on this bill. They gave evidence on two occasions and handed in memoranda containing suggested amendments to the bill.

Medical Inspection of Schools.—Correspondence was read from several Branches with regard to the medical inspection of scholars and school buildings. It was resolved that the opinion of the South African Committee and that of the Provincial Education Department was that a whole-time medical inspector of schools should be appointed, with such assistance as might be required.

District Surgeons' Grievances.—Correspondence was read with regard to the grievances of district surgeons. It was resolved to appoint a deputation to interview the Minister of the Interior on the subject and that Dr. W. A. Cameron, Secretary of the District Surgeons' Association, should be asked to co-operate.

On September 24th a special meeting of the South African Committee was held at the Defence Head Quarters, Pretoria, when Colonel Stock, D.M.S., by invitation of the

President, made an important statement with regard to the medical needs of the Defence Department of the Union. After discussion it was unanimously resolved to adopt the principle of voluntary conscription of all members of the British Medical Association in South Africa, and to recommend that each Branch should appoint a Medical Services Committee, whose business it would be to select practitioners for military duty, and to safeguard the interests of those absent on service. A special sub-committee of six was appointed to represent the committee on all questions relating to military medical services, and to act as an intermediary between the Branches of the Association and the Defence Department.

Meetings of Branches and Divisions.

EDINBURGH BRANCH: EDINBURGH AND LEITH DIVISION.

A MEETING of the Division was held on December 11th, when Dr. W. STEWART presided.

The Executive intimated that congratulations had been sent to Dr. George Mackay on his receiving a bar to the M.C., and to Dr. J. H. H. Pearson on receipt of a Belgian honour; also condolence on the decease of Dr. Elsie Inglis.

Increase of Fees.—The subject of the increase of fees was considered on receipt of a letter from the Scottish Committee. The SENIOR SECRETARY summarized correspondence and information received from the clerk to the Scottish Committee on action taken by the Aberdeen, Perth and Glasgow and West of Scotland Branches, and reported that the Leith practitioners had agreed to raise the ordinary fee where practicable; and the general feeling was that the fees should be left to the discretion of each practitioner, but that an increase could be made. After much deliberation it was unanimously resolved:

That this Division is of opinion that professional fees should be increased where circumstances will permit.

A motion that the resolution be sent to the whole profession in Edinburgh and Leith was lost.

City Welfare Nurses.—Questions in the schedule of the City Welfare Nurses were discussed and the following motion carried:

That the schedule of questions of the City Welfare Nurses should not be asked in cases where the patients employ a private registered medical attendant.

It was also resolved to send the resolution to the Medical Officer of Health, the Convener of the Public Health Committee, and the Town Clerk. Dr. R. ROBERTSON protested against this last motion.

INSURANCE.

LOCAL MEDICAL AND PANEL COMMITTEES.

Cheshire.—At a meeting of the Local Medical and Panel Committee on October 7th Dr. Picton was appointed representative of the Committee on the Joint Disablement Subcommittee for the county. It was decided to draw attention to the inadequate representation of the interests of panel practitioners upon the medical section of the Statutory Advisory Committee under the Insurance Acts.

At a meeting on October 28th it was resolved to inform the Commissioners that no system of payment by capitation could, in the opinion of the Committee, be satisfactory to the profession unless based upon the actual lists at some given date in arrears, and not, as at present, on a system of estimate and conjecture.

At a meeting on November 11th it was decided to issue the following document to each member of the panel for signature and immediate return to the secretary, but that the forms be not issued as resignations without the further consent of the signatories:

I hereby give notice in accordance with Medical Benefit Regulations (England) 1913, 17(2), that I desire to discontinue Panel Service on the present terms of payment at the expiry of the current year; but that I will undertake service at the capitation rate of 10s. per head per annum (exclusive of drugs and appliances) calculated on the list of persons accepted by or assigned to me under Section 25 of Part III of Medical Benefit Regulations.

At a meeting on November 17th it was resolved to recommend to the district Medical Committees that the

resignations be sent in to the Cheshire Insurance Committee, with a covering letter. On November 19th, 170 resignations were handed in, with a long covering letter stating that they were subject to the qualifications:

1. The signatories are willing to accept service at the rate of 10s. per head per annum (exclusive of drugs and appliances) calculated on the list of persons accepted by or assigned to them under Section 25.

2. Should the Insurance Acts Committee of the British Medical Association, after the negotiations which they are at present conducting with the Commissioners, conclude a settlement satisfactory to the whole profession, then the signatories would be willing to accept that settlement and withdraw their resignations.

The letter went on to state that the Local Medical and Panel Committee would have advised its constituents to await the result of these negotiations before taking action had it not been that the terms of the Regulations required six weeks' notice of resignation before the commencement of any insurance year.

Birmingham.—At a meeting of the Panel Committee on December 4th it was reported that the prescriptions in the local pharmacopoeia had been reviewed by representatives of the Panel, Pharmaceutical, and Insurance Committees, and that alterations necessitated by the conjoint action of the British Medical Association and the Pharmaceutical Society had been made. It was decided to sign Memo. 19 supporting the Insurance Acts Committee of the British Medical Association should it be found necessary to carry into effect the scheme for collective bargaining as approved by the October, 1917, Conference of Local Medical and Panel Committees.

Nottingham.—At a joint meeting of the Nottingham City and County panel practitioners on November 27th it was decided loyally to support the Insurance Acts Committee of the British Medical Association if it should be necessary to use the scheme of collective bargaining as set out in Memo. 18.

Warwickshire.—At a meeting of the Panel Committee on November 21st it was resolved that the Insurance Committee be asked to arrange for payment of medicines supplied to invalided men under the new arrangements at a flat rate based upon the average cost per prescription for 1916. It was resolved loyally to support the Insurance Acts Committee of the British Medical Association should it be found necessary to carry into effect the scheme for collective bargaining as approved by the October (1917) Conference. A report was received as to the settlement for 1916 showing that the capitation fee for dispensing was 1s. 9.21d. and for ordinary patients 6s. 7d. It was agreed that the War Emergency Formularies be adopted from December 1st unless otherwise expressly ordered by the prescriber.

Forfarshire.—At a general meeting of the Local Medical and Panel Committees on October 3rd it was agreed to endeavour to carry out as far as possible the regulations in reference to discharged disabled sailors and soldiers, but to inform the British Medical Association that the meeting considered the adoption of these regulations was *ultra vires* without consultation with and the approval and knowledge of Local Medical and Panel Committees in the first instance, and to call upon the Association without undue delay to have the regulations rescinded and a scheme laid before practitioners for their opinion, especially in regard to adequate remuneration for attendances including mileage.

Renfrewshire.—At a meeting of the Panel Committee on October 24th the Secretary reported that he had drawn the attention of the British Medical Association to the fact that the dividend rate of remuneration for attendance on temporary residents was very much lower in Scotland than in England, and that the point had been noted by the Insurance Acts Subcommittee (Scotland) for discussion with the Commissioners on the occasion of the first conference. The Secretary was instructed to add a clause to the Renfrewshire agreement authorizing a levy up to 1d. per insured person for the Committee's administrative expenses.
